TORONTO NOTES

COMPREHENSIVE MEDICAL REFERENCE & REVIEW FOR MCCQE I & USMLE II

Editors-in-Chief:
Yingming Amy Chen & Christopher Tran

THE TORONTO NOTES 2011

Comprehensive medical reference and review for the
Medical Council of Canada Qualifying Exam Part 1 and the
United States Medical Licensing Exam Step 2

27th Edition

Editors-in-Chief:

Yingming Amy Chen and Christopher Tran

*Wherever the art of medicine is loved,
there is also a love of humanity.*

Notice:

THIS PUBLICATION HAS NOT BEEN AUTHORED, REVIEWED OR OTHERWISE SUPPORTED BY THE MEDICAL COUNCIL OF CANADA NOR DOES IT RECEIVE ENDORSEMENT BY THE MEDICAL COUNCIL AS REVIEW MATERIAL FOR THE MCCQE. THIS PUBLICATION HAS NOT BEEN AUTHORED, REVIEWED OR OTHERWISE SUPPORTED BY THE NATIONAL BOARD OF MEDICAL EXAMINERS U.S.A. NOR DOES IT RECEIVE ENDORSEMENT BY THE NATIONAL BOARD AS REVIEW MATERIAL FOR THE USMLE.

The editors of this edition have taken every effort to ensure that the information contained herein is accurate and conforms to the standards accepted at the time of publication. However, due to the constantly changing nature of the medical sciences and the possibility of human error, the reader is encouraged to exercise individual clinical judgement and consult with other sources of information that may become available with continuing research. The authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this textbook, atlas, or software and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. In particular, the reader is advised to check the manufacturer's insert of all pharmacologic products before administration.

Library of Congress Cataloging-in-Publication Data is available upon request

To the contributors of past, present and future editions,

and

*To the families, friends, and loved ones of those who participated
in the Toronto Notes 2011 production – your support and
understanding were invaluable in the success of this project!*

Thank You!

The Toronto Notes is dedicated to helping fund many charitable endeavours and medical student initiatives at the University of Toronto's Faculty of Medicine. Programs that have received Toronto Notes funding include:

Community Affairs Projects

- Saturday Program for Inner City High School and Grade 8 students
- St. Felix Mentorship Program for Inner City children
- Parkdale Mentorship Program for Grade 10-12 students
- WoodGreen Community Centre
- Let's Talk Science
- Growing Up Healthy

Annual Faculty Showcase Events

- Daffydil, in support of the Canadian Cancer Society
- Earthtones Benefit Concert
- Clerkship Luncheon

Medical School Clubs

- Books with Wings
- Women in Medicine
- University of Toronto International Health Program
- Complementary and Alternative Medicine
- Peer Support for Students
- History of Medicine Society
- Faculty of Medicine Yearbook

Graduating Class

- Bruce Tovee Lecture Series
- Convocation and Ceremonies
- Scholarships and Bursaries

NOTE:

Many of you have wondered about the *Toronto Notes* logo, which is based on the rod of Asclepius, the Greek god of medicine. The rod of Asclepius consists of a single serpent entwined around a staff. This icon symbolizes both rebirth, by way of a snake shedding its skin, and also authority, by way of the staff.

In ancient Greek mythology, Asclepius was the son of Apollo and a skilled practitioner of medicine who learned the medical arts from the centaur Chiron. Asclepius' healing abilities were so great that he was said to be able to bring back people from the dead. These powers displeased the gods, who punished Asclepius by placing him in the sky as the constellation Orphiuchus.

The rod of Asclepius is at times confused with the caduceus, or wand, of Hermes, a staff entwined with two serpents and often depicted with wings. The caduceus is often used as a symbol of medicine or medical professionals, but there is little historical basis for this symbolism.

As you may have guessed, our logo uses the rod of Asclepius that is modified to also resemble the CN Tower – our way of recognizing the university and community in which we have been privileged to learn the art and science of medicine.

Thomas O'Brien, HBSc, MD
Class of 2009
M.D. Program, University of Toronto

Preface – From the Editors

Dear Readers,

Toronto Notes is a concise and comprehensive medical review revised annually by the University of Toronto graduating medical class under the guidance of leading experts within the Faculty of Medicine. This reference text started as a compilation of notes written by and shared among University of Toronto students to study for their medical licensing exams. After 27 years, it has become a reputable study guide used by medical students across Canada and around the world. This transformation could not have happened without the dedication of students who ensure that each edition contains the latest evidence-based information on 29 subspecialties of Medicine. This year has been no different: over 100 staff worked tirelessly to complete this edition.

Since its inception, *Toronto Notes* has been a non-profit organization where revenue is used to fund University of Toronto medical student initiatives including community outreach, international health projects, charitable performances, and graduating class scholarships and bursaries. On behalf of the *Toronto Notes* production team, we would like to thank the support from thousands of medical students around the world by purchasing our book.

The 27th edition of *Toronto Notes* offers exciting new changes to further enhance your exam preparation. We have included over 20 new original medical illustrations, updated our online colour atlas with new images and annotations, and revised our evidence-based medicine reviews. We also have a new learning module: the Approach to Ultrasound in the Emergency Department, created to help medical students understand the basics of ultrasound imaging in trauma and other emergencies. In addition, we have included over 50 Objective Structured Clinical Examination (OSCE) scenarios with history and physical exam checklists for practice purposes that can be found online. We have also separated our popular *Clinical Handbook* into four pocket reference guides for easy portability.

As readers, we appreciate your feedback. This year, we have spent considerable time improving the scientific and writing accuracy of our publications. Many of those changes originated from your comments submitted online on our website. Having travelled across the country for electives, we appreciate how so many medical students value *Toronto Notes* for studying during clinical rotations and exam preparation. We therefore understand the trust placed in our publication and realize our crucial task in upholding the accuracy of our content.

Thank you very much for purchasing the 2011 edition of *Toronto Notes*. We hope it will serve you well in all of your future medical endeavours.

Sincerely,

Yingming Amy Chen

How to Use This Book

This book has been designed to remain as one book or to be taken apart into smaller booklets. Identify the beginning and end of a particular section, then carefully bend the pages along the perforated line next to the spine of the book. Then tear the pages out along the perforation.

The layout of *Toronto Notes 2011* allows easy identification of important information. These items are indicated by icons interspersed throughout the text:

Icon	Significance
	The 'key' icon, found next to headings in the text, identifies key objectives and causal conditions as defined by the Medical Council of Canada or the National Board of Medical Examiners USA. If it appears beside a 'black-bar' title, all subsequent subheadings should be considered key topics.
	The 'pearl' icon, found in the sidebar, identifies concise, important information which will aid in the diagnosis and/or management of conditions discussed in the accompanying text.
	The 'light bulb' icon indicates helpful mnemonic devices and other memory aids.
	The 'flag' icon indicates information or findings that require urgent management or specialist referral.
	The 'camera' icon indicates topics that correspond with images found in the Colour Photo Atlas available online.
	The 'X-ray' icon indicates topics that correspond to information or images contained within the Radiology Atlas located online.
	The 'computer' icon indicates topics that correspond with electronic resources such as Functional Neuroanatomy™ or ECG Made Simple™ located online.

Chapter Divisions

To aid in studying and finding relevant material quickly, each chapter is organized in the following general framework:

Basic Anatomy/Physiology Review

- features the high-yield, salient background information students are often assumed to have remembered from their early medical school education

Common Differential Diagnoses

- aims to outline a clinically useful framework to tackle the common presentations and problems faced in the area of expertise

Diagnoses

- the bulk of the book
- etiology, epidemiology, pathophysiology, clinical features, investigations, management, complications, and prognosis

Common Medications

- a quick reference section for review of medications commonly prescribed

Ethical, Legal and Organizational Aspects of Medicine

Trevor Arnason and Shuo Chen, chapter editors
Christopher Kitamura and Michelle Lam, associate editors
Janine Hutson, EBM editor
Dr. Philip Hébert, staff editor

Legal Matters 2

The Doctor-Patient Relationship under the Law

Legal Matters

The Doctor-Patient Relationship under the Law

N.B.: Canadian law applicable to medical practice varies between jurisdictions and changes over time.

- Criminal law is nationwide, but non-criminal (civil) law varies between provinces.
- This section is meant to serve only as a guide; students and physicians should ensure that their practices conform to local and current laws.

Fiduciary duty: obligation to act in the patient's best interests

- laws which regulate doctor-patient relationship function to protect patients
- derived from three sources: 1) **common law** (in Quebec, the *Civil Code of Quebec*), 2) **statutes** and 3) **the Constitution**
- **common law:** body of legal rules and principles derived from judges' decisions that forms the basis of the Anglo-Canadian legal system, includes:
 - *tort law* that allows patients to recover damages for wrongful acts committed against them. The most important are 1) *negligence* (see *Negligence and Liability*, ELOAM6) and 2) *battery* (the application of force to a person's body without their consent)
 - the doctor-patient relationship is a contract of *contractual rights and obligations* that if breached may result in the award of damages
 - a doctor also has a *fiduciary* duty to their patient
- **statutes** are laws passed by provincial legislatures and the federal parliament, for example:
 - in Ontario, the *Health Care Consent Act* regulates consent to treatment (see *Consent under the Law*, ELOAM2)
 - the *Personal Health Information Protection Act* regulates the collection, use and disclosure of health records (see *Privacy of Medical Records*, ELOAM5)
- **the Constitution** is the supreme law of Canada; all other laws must be consistent with it
 - the *Canadian Charter of Rights and Freedoms* guarantees the rights of life, liberty, security of the person, and equality under the law (among others)
 - these rights are subject only to such reasonable limits as can be demonstrably justified in a free and democratic society

Consent under the Law

- consent of the patient must be obtained before any medical intervention is provided. Consent can be:
 - oral or written, although written is usually preferred
 - implied (e.g. a patient holding out their arm for an immunization) or expressed
- consent is an ongoing process and can be withdrawn or changed after it is given
- *Health Care Consent Act* covers consent to treatment, admission to a facility, and personal assistance services (e.g. home care)

Exceptions to Consent

1. Emergencies

- treatment can be provided without consent where a patient is experiencing severe suffering, OR where a delay in treatment would lead to serious harm or death AND consent cannot be obtained from the patient or their substitute decision maker (SDM)
- emergency treatment should not violate a prior expressed wish of the patient (e.g. a signed Jehovah's Witness card)
- if patient incapable, MD must document reasons for incapacity and why situation is emergent
- if a SDM is not available, MD can treat without consent until the SDM is available or the situation is no longer emergent

2. Legislation

- Mental Health legislation allows for:
 - ♦ the detention of patients without their consent (see *Consent*, ELOAM8)
 - ♦ psychiatric outpatients to be compelled to adhere to a care plan in accordance with Community Treatment Orders (see *Psychiatry*, PS51)
- Public Health legislation allows medical officers of health to detain, examine, and treat patients without their consent (e.g. a patient with TB refusing to take medication) to prevent transmission of communicable diseases (see *Population and Community Health*, PH4)

3. Special Situations

- public health emergencies (e.g. an epidemic or communicable disease treatment)
- warrant for information by police

Major Exceptions to Consent

- Emergencies
- Communicable diseases
- Mental Health legislation

Four Basic Requirements of Valid Consent

1. Voluntary

- consent must be given free of coercion or pressure
- the physician must not deliberately mislead the patient about the proposed treatment

2. Capable

- the patient must be able to understand the nature and effect of the proposed treatment

3. Specific

- the consent provided is specific to the procedure being proposed and to the provider who will carry out the procedure (i.e. the patient must be informed if students will be involved in providing the treatment)

4. Informed

- sufficient information must be provided to allow the patient to make choices in accordance with their wishes. This information should include:
 - ◆ the nature of the treatment or investigation proposed and its expected effects
 - ◆ all significant risks and special or unusual risks
 - ◆ alternative treatments or investigations and their anticipated effects and significant risks
 - ◆ the consequences of declining treatment
 - ◆ risks that are common sense need not be disclosed (i.e. bruising after venipuncture)
- **the reasonable person test** – the physician must provide all information that would be needed “by a reasonable person in the patient’s position” to be able to make a decision
 - ◆ disclose common adverse events (>1/200 chance of occurrence) and serious risks (e.g. death) even if remote
- it is the physician’s responsibility to make reasonable attempts to ensure that the patient understands the information
- physicians cannot withhold information about a therapeutic option based on personal conscience (e.g. not discussing the option of emergency contraception)

The Supreme Court of Canada expects physicians to disclose the risks that a “reasonable” person would want to know. In practice, this means disclosing minor risks that are common as well as serious risks that happen infrequently.

Consequences of Failure to Obtain Valid Consent

- treatment without consent is battery, even if the treatment is life-saving
- treatment of a patient on the basis of poorly informed consent may constitute negligence
- the onus of proof that valid consent was not obtained rests with the plaintiff (usually the patient)

Capacity and Substitute Decision Makers (see *Assessing Capacity*, ELOAM9)

- capable patients are entitled to make their own decisions
- capacity assessments must be conducted by a physician and, if appropriate, in consultation with other health care professionals (e.g. another physician, a mental health nurse)
- capable patients can refuse treatment even if it leads to serious harm or death; however, decisions that put patients at risk of serious harm or death require careful scrutiny

Consent

Treatment without consent = battery, including if NO consent or if **WRONG** procedure

Treatment with poor or invalid consent = negligence

Substitute Decision Makers (SDMs)

- SDM must follow the following principles when giving informed consent:
 - act in accordance with wishes previously expressed by the patient while capable
 - if wishes unknown, act in the patient’s best interest, taking the following into account:
 1. values and beliefs held by the patient while capable
 2. whether well-being is likely to improve with vs. without treatment
 3. whether the expected benefit outweighs the risk of harm
 4. whether a less intrusive treatment would be as beneficial as the one proposed
 - the final decision of the SDM may and should be challenged by the MD if the MD believes the SDM is not abiding by the above principles
- most provinces have legislated hierarchies for SDMs; the hierarchy in Ontario is:
 1. legally appointed guardian
 2. appointed attorney for personal care, if a power of attorney confers authority for treatment consent (see *Power of Attorney*, ELOAM4)
 3. representative appointed by the Consent and Capacity Board
 4. spouse or partner
 5. child (age 16 or older) or parent (unless the parent has only a right of access)
 6. parent with only a right of access
 7. sibling
 8. other relative(s)
 9. public guardian and trustee

If the MD feels the SDM is not acting in the patient’s best interest, the MD can apply to Consent and Capacity Board for another SDM.

Administration of treatment for an incapable patient in an emergency situation is applicable if the patient is:

1. Experiencing extreme suffering
2. At risk of sustaining serious bodily harm if treatment is not administered promptly

Treatment of the Incapable Patient

- obtain informed consent from SDM
- an incapable patient can only be detained against his/her will to receive treatment if he/she meets criteria for certification under the *Mental Health Act* (see *Psychiatry*, PS51). In such a situation:
 - document assessment in chart
 - notify patient of assessment using appropriate Mental Health Form(s) (Form 42)
 - notify Rights Advisor

There is no age of consent.

Pediatric Aspects of Capacity Covered by the HCCA

- no age of consent; consent depends on patient's decision-making ability (capacity) N.B. PEI, NB, QC, SK, BC have specific age of consent, but common law and case law deem underage legal minors capable, allowing them to make their own choices
- infants and children are assumed to lack mature decision-making capacity for consent but they should still be involved (i.e. be provided with information appropriate to their comprehension level)
- adolescents are usually treated as adults
- preferably, assent should still be obtained from patient, even if not capable of giving consent
- in the event that the physician believes the SDM is not acting in the child's best interest, an appeal must be made to the local child welfare authorities
- under normal circumstances, parents have right of access to the child's medical record

Criteria for Financial Competence

- covered by the *Mental Health Act* and *Substitute Decision Act*
- patient must:
 - appreciate importance of financial capability and reason for exam
 - have realistic appreciation of own strengths/weaknesses in managing finances
 - understand nature and extent of assets, liabilities, income, and expenses
 - have recently demonstrated ability to make reasonable financial decisions and be expected to do so in future
 - have appropriately used available resources and indicate willingness to do so in future
- if MD determines the patient incapable of managing property, a Form 21 is completed and the Public Guardian and Trustee becomes the temporary guardian until a substitute can be found; eligible substitute guardians are patient's spouse/partner, relative, or attorney
- Form 21 can only be filled out if the patient is an inpatient of a psychiatric facility; to continue financial incapacity after discharge, fill out Form 24

Other Types of Capacity Not Covered by the HCCA

- Testamentary (ability to make a will)
- Fitness (ability to stand trial)
- Financial (ability to manage property – Form 21 of the *Mental Health Act*)
- Personal (ability to care for oneself on a daily basis)

Instructional Advance Directives

- allow patients to exert control over their care once they are no longer capable
- the patient sets out their decisions about future health care, including who they would allow to make treatment decisions on their behalf and what types of interventions they would want
- takes effect once the patient is incapable with respect to treatment decisions
- in Ontario, a person can appoint a power of attorney for personal care to carry out his/her advance directives
- patients should be encouraged to review these documents with their family and physicians and to reevaluate them often to ensure they are current with their wishes

Power of Attorney (POA)

LEGAL TERMS AND DEFINITIONS

- all Guardians and Attorneys for Personal Care have fiduciary duties for the dependent person

Power of Attorney for Personal Care

- a legal document in which one person gives another the authority to make personal care decisions (health care, nutrition, shelter, clothing, hygiene, safety) on their behalf if they become mentally incapable

Guardian of the Person

- someone who is appointed by the Court to make decisions on behalf of an incapable person in some or all areas of personal care, in the absence of a POA for personal care

Continuing Power of Attorney for Property

- a legal document in which a person gives another the legal authority to make decisions about their finances if they become unable to make those decisions

Guardian of Property

- someone who is appointed by the Public Guardian and Trustee or the Courts to look after an incapable person's property or finances

Public Guardian and Trustee

- acts as a SDM of last resort on behalf of mentally incapable people who do not have another individual to act on their behalf

Confidentiality and Reporting Requirements

- the legal duty to maintain patient confidentiality is imposed by provincial health information legislation and precedent-setting cases in the common law
- the right to confidentiality is not absolute
- disclosure of health information can take place with the patient's consent or without the patient's consent in certain circumstances defined by statutory and common law

Statutory Reporting Obligations

- legislation has defined specific instances where public interest overrides the patient right to confidentiality; varies by province, but may include:
 1. suspected child abuse or neglect – report to local child welfare authorities (e.g. Children's Aid Society)
 2. fitness to drive a vehicle or fly an airplane – report to provincial Ministry of Transportation (see *Geriatric Medicine*, GM9)
 3. communicable diseases – report to local public health authority (see *Population and Community Health*, PH27)
 4. improper conduct of other physicians or health professionals – report to college or regulatory body of the health professional (sexual impropriety by physicians is required reporting in some provinces)
 5. vital statistics must be reported; reporting varies by province (in Ontario, births are required to be reported within 30 days to Office of Registrar General or local municipality; death certificates must be completed by a MD then forwarded to municipal authorities)
 6. reporting to coroners (see *Physician Responsibilities Regarding Death*, ELOAM20)
- physicians who fail to report in these situations are subject to prosecution and penalty, and may be liable if a third party has been harmed

Duty to Protect/Warn

- the physician has a duty to protect the public from a known dangerous patient; this may involve taking appropriate clinical action (e.g. involuntary detainment of violent patients for clinical assessment), informing the police, or warning the potential victim(s) if a patient expresses an intent to harm
- first established by a Supreme Court of California decision in 1976; supported by Canadian courts
- obliged by the CMA Code of Ethics and recognized by some provincial/territorial regulatory authorities
- concerns of breaching confidentiality should not prevent the MD from exercising the duty to protect; however, the disclosed information should not exceed that required to protect others
- applies in a situation where:
 1. there is a clear risk to identifiable person(s);
 2. there is a risk of serious bodily harm or death; and
 3. the danger is imminent (i.e. more likely to occur than not)

Disclosure for Legal Proceedings

- disclosure of health records can be compelled by a court order, warrant, or subpoena

Privacy of Medical Records

- privacy of health information is protected by professional codes of ethics, provincial and federal legislation, the *Canadian Charter of Rights and Freedoms*, and the fiduciary duty
- the federal government created the *Personal Information Protection and Electronic Documents Act* (PIPEDA), which established principles for the collection, use, and disclosure of information that is part of commercial activity (e.g. physician practices, pharmacies, private labs)
- PIPEDA has been superseded by provincial legislation in many provinces, such as the *Ontario Personal Health Information Protection Act*, which applies more specifically to health information

Duties of Physicians with Regards to the Privacy of Health Information

- inform patients of information-handling practices through various means (e.g. posting notices, brochures and pamphlets, and/or through discussions with patients)
- obtain the patient's express consent to disclose information to third parties
 - under Ontario privacy legislation, the patient's express consent needs not be obtained to share information between health care team members involved in the "circle of care." However, the patient may withdraw consent for this sharing of information.
- provide the patient with access to their entire medical record; exceptions include instances where there is potential for harm to the patient or a third party
- provide secure storage of information and implement measures to limit access to patient records
- ensure proper destruction of information that is no longer necessary

Legal Aspects of Confidentiality

Advice should always be sought from provincial licensing authorities and/or legal counsel when in doubt.

Ontario's Medical Expert Panel on Duty to Warn

Ferris et al., 1998

There should be a duty to inform when a patient reveals that he/she intends to do serious harm to another person(s) and it is more likely than not that the threat will be carried out.

Where a threat is directed at a person or group and there is a specific plan that is concrete and capable of commission and the method for carrying it out is available to the threatener, the physician should immediately notify the police and, in appropriate circumstances, the potential victim. The report should include the threat, the situation, the physician's opinion and the information upon which it is based.

CMA Code of Ethics

- Protect the health information of your patients.
- Provide information reasonable in the circumstances to patients about the reasons for the collection, use and disclosure of their health information.
- Be aware of your patient's rights with respect to the collection, use, disclosure and access to their health information; ensure that such information is recorded accurately.

Negligence and Liability

- **negligence**: breach of a legal duty of care which results in damage
 - legal finding, not a medical one
- physicians may be found negligent when the following four conditions are met:
 1. the physician owed a **duty of care to the patient** (the existence of a doctor-patient relationship generally suffices)
 2. the **duty of care was breached** (e.g. by failure to provide the **standard of care**)
 3. the patient was **injured or harmed**
 4. the harm or injury **was caused** by the breach of the duty of care
- the **standard of care** is one that would reasonably be expected under similar circumstances of an ordinary, prudent physician of the same training, experience, and specialization
- errors of judgement are not necessarily negligent
 - making the wrong diagnosis is not negligent if a reasonable doctor might have made the same mistake in the same circumstances
 - failure to reconsider the diagnosis if the patient does not respond to treatment may be negligent
- physicians can be held liable for the negligent actions of their employees or other individuals they are supervising

Physician Competence and Conduct

- the competence and conduct of physicians is legally regulated in certain respects to protect patients and society
- physicians are legally required to maintain a license with the appropriate authority
- physicians must ensure that patients have access to continuous on-call coverage and are never abandoned
- sexual conduct with patients, even when consented to by the patient, is a serious matter that can lead to criminal, civil, and disciplinary action
 - sexual conduct includes intercourse, undue touching, inappropriate reference to sexual matters, sexual jokes, and physician presence when capable patients undress or dress
 - physicians may have a personal relationship with a patient providing a year has passed since the last therapeutic contact
 - physicians are prohibited from personal relationships with patients whom they saw for psychotherapy
 - in Ontario, physicians must report any colleagues of whom they have information regarding sexual impropriety
- physicians must maintain adequate records for each patient, including:
 - showing that care has been continuous and comprehensive
 - minimal standards for record-keeping include diagnosis, differential diagnosis, appropriate tests and referrals, coherent patient record (full standards available at www.cpsso.on.ca)
 - keeping records for 10 years in most jurisdictions
 - although the medical record is the property of the physician or an institution, the patient or the patient's delegate must be allowed full access to information in the medical record upon (usually written) request
- in the hospital, physicians must ensure their own competence, respect hospital by-laws and regulations, practice only within the limits of granted privileges, cooperate with other hospital personnel, and maintain adequate hospital records

CMA Code of Ethics

Report any unprofessional conduct by colleagues to the appropriate authority.

Ethics

Principles of Ethics

- ethics deals with 1) the principles and values that help define what is morally right and wrong, and 2) the rights, duties and obligations of individuals and groups
- there are two broad approaches to ethics: **consequentialism** and **deontology**
 - consequentialism distinguishes right from wrong according to an action's outcomes (i.e. the right thing to do is minimize suffering) while deontology is rule or duty-based (i.e. it is always wrong to punish the innocent)
 - there is no one agreed upon ethical theory but most contemporary writers combine both approaches
 - most widely used approach is '**principlism**'

The Four Principles Approach to Medical Ethics ('principlism')

1. Respect for Autonomy

- recognizes an individual's right and ability to decide for themselves according to his/her beliefs and values
- respecting and promoting an individual patient's values in decision making to empower him or her
- a patient's decision may differ from the recommendation of the physician and the physician should understand, appreciate, and respect the patient's perspective
- patients are not expected to act in ways considered reasonable by others as long as they do not harm others (this principle is not applicable to newborn children or situations where informed consent and choice are not possible or may not be appropriate)
- autonomy also requires showing fidelity to incapable patients' prior capable views if known, and treating them with worth and dignity

2. Beneficence

- acting in the patient's 'best interests', where these represent the patient's values, beliefs, and preferences, so far as these are known
- the aim is to minimize harmful outcomes and maximize beneficial ones
- physicians recommend treatment based on evidence and professional experience to patients and help them weigh the risks and benefits of various options
- autonomy should be integrated with the physician's conception of a competent patient's best interests
- paramount in situations where consent/choice is not possible or may not be appropriate

3. Non-Maleficence

- obligation to avoid causing harm; *primum non nocere* ("First, do no harm")
- efforts should be made to reduce error and adverse events and ensure patient safety
- a limit condition of the Beneficence principle

4. Justice

- fair distribution of benefits and harms within a community, regardless of geography or privilege
- scarce resources are distributed based on the needs of patients and the benefit they would receive from obtaining a specific resource (e.g. organs for transplantation are fairly distributed if they go to those who are the most unwell, who are the most likely to survive the longest with the transplant, and who have waited the longest to receive a transplant)
- concept of fairness: Is the patient receiving what he/she deserves? How do treatment decisions impact on others?
- respects rules of fair play and basic human rights, such as freedom from persecution and the right to have one's interests considered and respected

Four Ethical Principles

1. Autonomy
2. Beneficence
3. Non-maleficence
4. Justice

Autonomy vs. Competence

Autonomy: the right that patients have to make decisions according to their beliefs and preferences

Competence: the ability or capacity to make a specific decision for one's self

Adverse Event (AE)

An unintended injury or complication from health care management resulting in disability, death or prolonged hospital stay.

The Canadian Adverse Events Study: The Incidence of Adverse Events among Hospital Patients in Canada

CMAJ 2004; 170(11):1678-86

Study: Review of random sample of charts in four randomly selected Canadian hospitals for the fiscal year 2000.

Patients: 4174 patient charts sampled, 3745 eligible charts (>18 years of age; nonpsychiatric, nonobstetric, minimum 24 hour admission).

Results: AE rate was 7.5% per 100 hospital admissions (95% CI 5.7-9.3). Highly preventable AEs occurred in 36.9% of patients with AEs (95% CI 32.0-41.8%) and death occurred in 20.8% (95% CI 7.8%-33.8%). An estimated 1521 additional hospital days were associated with AEs. Patients with AEs were significantly older than those without (mean age [and standard deviation] 64.9 [16.7] v. 62.0 [18.4] years; $p=0.016$). Men and women experienced equal rates of AEs.

Conclusions: The overall incidence rate of AEs of 7.5% suggests that, of the almost 2.5 million annual hospital admissions in Canada similar to the type studied, about 185 000 are associated with an AE and close to 70 000 of these are potentially preventable.

Code of Ethics

- the CMA has developed and approved a **Code of Ethics** that acts as a common ethical framework for Canadian physicians
 - sources include the Hippocratic Oath, developments in human rights, recent bioethical discussion
 - may set out different standards of behaviour than does the law
 - prepared by physicians for physicians
 - based on the fundamental ethical principles of medicine
 - statements are general in nature
 - applies to physicians, residents, and medical students

The CMA Code of Ethics is a quasi-legal standard for physicians. If the law sets a minimal moral standard for doctors, the Code ratchets up these standards.

- **CMA policy statements** address specific ethical issues not mentioned by the code (e.g. abortion, transplantation, and euthanasia)
- the American Medical Association (AMA) has a **Code of Medical Ethics**
 - articulates the values of medicine as a profession
 - defines medicine's integrity and is the source of the profession's authority to self-regulate
 - considered an evolving document that changes as new questions arise concerning medicine's core values and its application to daily practice
- the AMA develops policy positions ("AMA Policy") regarding health care issues, the health care system, internal organizational structure, decision-making processes, and medical science and technology

Confidentiality

Reasons to Breach Confidentiality

- Child abuse
- Fitness to drive
- Communicable disease
- Coroner report
- Duty to inform/warn

CMA Code of Ethics

"Disclose your patients' personal health information to third parties only with their consent, or as provided for by law, such as when the maintenance of confidentiality would result in a significant risk of substantial harm to others or, in the case of incompetent patients, to the patients themselves. In such cases take all reasonable steps to inform the patients that the usual requirements for confidentiality will be breached."

- a full and open exchange of information between patient and physician is central to a therapeutic relationship
- privacy is a **right** of patients (which they may forego), while confidentiality is a **duty** of doctors (which they must respect barring patient consent or the requirements of the law)
- if inappropriately breached by a doctor, he/she can be sanctioned by the hospital, by the court or by his or her regulatory authority (see *Confidentiality and Reporting Requirements*, ELOAM5)
- based on the ethical principal of patient autonomy, patients have the right to:
 - control their own information
 - expect information concerning them will receive proper protection from unauthorized access by others (see *Privacy of Medical Records*, ELOAM5)
- **confidentiality may be ethically and legally breached in certain circumstances**, e.g. the threat of harm to others (see *Confidentiality and Reporting Requirements*, ELOAM5)
- unlike the solicitor-client privilege, there is no 'physician-patient privilege' by which a physician, even a psychiatrist, can promise the patient absolute confidentiality
- physicians should seek advice from their local health authority or the Canadian Medical Protective Association (CMPA) before disclosing HIV status of a patient to someone else
 - many jurisdictions make mandatory not only the reporting of serious communicable diseases (e.g. AIDS), but also the reporting of those who harbour the agent of the communicable disease
 - physicians failing to abide by such regulations could be subject to professional or civil actions

Consent

CPSO Policy Consent

Obtaining valid consent before carrying out medical, therapeutic and diagnostic procedures has long been recognized as an elementary step in fulfilling the doctor's obligations to the patient.

- the autonomous authorization of a medical intervention by a patient
- applies to acceptance and refusal of treatment
- also see *Consent under the Law*, ELOAM2

Ethical Principles Underlying Consent

- usually the principle of respect for patient autonomy overrides the principle of beneficence
- where a patient cannot make an autonomous decision, it is the duty of the SDM (or the physician in an emergency) to act on the patient's known prior wishes or, failing that, to act in the patient's best interests
- there is a duty to discover, if possible, what the patient would have wanted when capable
- central to determining best interests is understanding the patient's values, beliefs, and cultural or religious background since these may affect the patient's perception of treatments as beneficial or harmful
- more recently expressed wishes should take priority over remote ones
- patient preferences may be given orally (i.e. do not have to be in written form)

Obtaining Consent

- a signed consent form only documents the consent – it does not replace the process for obtaining valid consent (see Figure 1)
- what matters is what the patient understands and appreciates, not what the signed consent form states
- consent can be withdrawn at any point, unless stopping a procedure would put the patient at risk of serious harm
- consent is not required in certain situations (see *Consent under the Law*, ELOAM2)

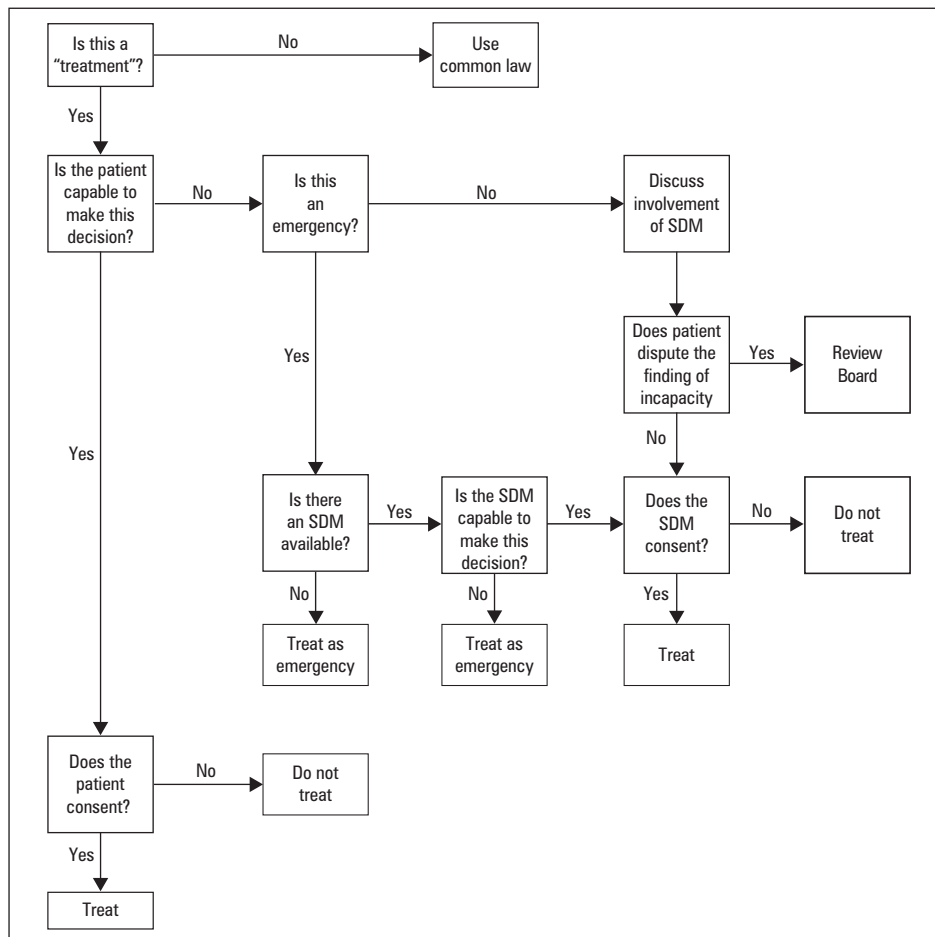

Figure 1. Consent Flowchart

SDM = substitute decision maker

Adapted by P. Hébert from Sunnybrook Health Sciences Centre Consent Guidelines

Assessing Capacity

- a person is presumed capable unless there is good evidence to the contrary
- capacity is the ability to:
 - understand information relevant to a treatment decision
 - appreciate the reasonably foreseeable consequences of a decision or lack of a decision
- **capacity is specific** for each decision (e.g. a person may be capable to consent to having a chest x-ray, but not for a bronchoscopy)
- most Canadian jurisdictions distinguish capacity to make health care decisions from capacity to make financial decisions. A patient may be deemed capable of one, but not the other.
- **capacity can change over time** (e.g. temporary incapacity secondary to delirium)
- clinical capacity assessment may include:
 - specific capacity assessment (i.e. capacity specific to the decision at hand)
 1. effective disclosure of information and evaluation of patient's reason for decision
 2. understanding of:
 - his/her condition
 - the nature of the proposed treatment
 - alternatives to the treatment
 - the consequences of accepting and rejecting the treatment
 - the risks and benefits of the various options (test: can the patient recite back what you have disclosed?)
 3. for the **appreciation** needed for decision making capacity, a person must:
 - acknowledge the condition that affects him/herself
 - be able to assess how the various options would affect him or her
 - be able to reach a decision and adhere to it, and make a choice, not based primarily upon delusional belief (test: are their beliefs responsive to evidence?)
 - general impressions
 - input from psychiatrists, neurologists, etc.
- employ "Aid to Capacity Evaluation" (see Table 1)

CPSO Policy Capacity

Capacity is an essential component of valid consent, and obtaining valid consent is a policy of the CMA and other professional bodies.

Table 1. Aid to Capacity Evaluation

Ability to understand the medical problem
Ability to understand the proposed treatment
Ability to understand the alternatives (if any) to the proposed treatment
Ability to understand the option of refusing treatment or of it being withheld or withdrawn
Ability to appreciate the reasonably foreseeable consequences of accepting the proposed treatment
Ability to appreciate the reasonably foreseeable consequences of refusing the proposed treatment
Ability to make a decision that is not substantially based on delusions or depression

Adapted from *Etchells et al.* (1996).

- a decision of incapacity may warrant further assessment by psychiatrist(s), legal review boards (e.g. in Ontario, the Consent and Capacity Review Board), or the courts
- judicial review is open to patients if found incapable
- see *Consent under the Law*, ELOAM2
- ethical principles underlying capacity
 - patient autonomy and respect for persons
 - physician beneficence requires that incapable persons be protected from making harmful decisions
 - even patients found incapable to make a specific decision should still be involved in that decision as much as possible (seek assent and cooperation and explore reasons for dissent)
 - people should be allowed to make their own informed decisions, or to appoint their own SDM
 - agreement or disagreement does not equal capacity

Truth Telling

Ethical Basis

- helps to promote and maintain a trusting physician-patient relationship
- patients have a right to be told important information that physicians have regarding their care
- enables patients to make informed decisions about health care and their lives

Legal Basis

- required for valid patient consent (see *Consent under the Law*, ELOAM2)
 - goal is to disclose information that a reasonable person in the patient's position would need in order to make an informed decision ("standard of disclosure")
- withholding information can be a breach of fiduciary duty and duty of care
- obtaining consent on the basis of misleading information can be seen as negligence

Evidence about Truth Telling

- most patients want to know what is wrong with them
- although many patients want to protect family members from bad news, they themselves would want to be informed in the same situation
- truth telling improves compliance and health outcomes
- informed patients are more satisfied with their care
- negative consequences of truth telling can include decreased emotional well-being, anxiety, worry, social stigmatization, and loss of insurability

Challenges in Truth Telling

- **medical error**
 - many jurisdictions and professional associations expect and require physicians to disclose medical error; any event that harms or threatens to harm patients must be disclosed to the patient or the patient's family and reported to the appropriate health authorities
 - physicians should disclose to patients the occurrence of adverse events or errors caused by medical management, but should not suggest that they resulted from negligence because:
 - a) negligence is a legal determination and b) error is not equal to negligence (see *Negligence and Liability*, ELOAM6)
 - disclosure allows the injured patient to seek appropriate corrective treatment promptly
 - ♦ physicians should avoid simple attributions as to cause and sole responsibility of others or oneself
 - ♦ physicians should offer apologies or empathic expressions of regret ("I wish things had turned out differently") as these can increase trust and are not admissions of guilt or liability
 - ♦ uniform *Apology Acts* across Canada protect apologies, both as expressions of regret and admissions of responsibility, from being used as evidence of liability and negligence
- **breaking bad news**
 - adequate support should be provided along with the disclosure of difficult news
 - SPIKES protocol was developed to facilitate "breaking bad news"

CPSO Policy Truth Telling

Physicians should provide patients with whatever information that will, from the patient's perspective, have a bearing on medical decision-making and communicate that information in a way that is comprehensible to the patient.

Protocol to Break Bad News: SPIKES

S **Setting** the scene and listening skills
P patient's **perception** of condition and seriousness
I **Invitation** from patient to give information
K **Knowledge** – giving medical facts
E **Explore** emotions and empathize
S **Strategy** and **summary**

WF Baile and R Buckman, 2000.

Arguments Against Truth Telling

- may go against certain cultural norms and expectations
- may lead to patient harm and increased anxiety
- 10-20% of patients prefer not to be informed
- medical uncertainty may result in the disclosure of uncertain or inaccurate information

Exceptions to Truth Telling

- waiving the right to know: patient declines information that would normally be disclosed
- physicians should explore such decisions and determine if patient is capable
- strong cultural or ethnic preferences for withholding information should be explored with the patient and it should be ascertained if the patient subscribes to these preferences
- if patients continue to decline important information, the patient's consent to inform someone else on their behalf should be sought
- a patient may waive their right to know the truth about their situation when
 - disclosure would in itself cause physical or mental harm to the patient
 - a strong cultural component exists that must be respected and acknowledged
 - the patient is incapacitated
 - he/she is in a medical emergency
 - the more weighty the consequences for the patient from non-disclosure, the more carefully one must consider the right to ignorance; arguably, such a patient could be considered as incapacitated and a SDM may need to be found to whom disclosure can be made
- the doctrine of therapeutic privilege is rarely acceptable in Canadian courts
 - refers to the withholding of information by the clinician in the belief that disclosure of the information would lead to anxiety, psychological distress or even self-harm. Such concerns have been found to be exaggerated and should not be grounds to deceive patients.
 - clinicians should avoid invoking therapeutic privilege and allow patients to make decisions based on an accurate description of their medical situation

Resource Allocation

- the distribution of goods and services to programs and people
- physicians have the duty to inform patients about therapeutic options even if they are not available
- ethics relate to **justice**: physicians must make health care resources available to patients in a manner which is fair and equitable, without bias or discrimination
 - need and benefit are morally relevant criteria for resource allocation
 - gender, sexual orientation, religion, level of education or age alone are morally irrelevant criteria
- ethical **dilemmas** that arise when deciding how best to allocate resources
 - fair chances versus best outcome – favouring best outcome vs. giving all patients fair access to limited resources (e.g. transplant list prioritization)
 - priorities problem – how much priority should treating the sickest patients receive?
 - aggregation problem – modest benefits to many vs. significant benefits to few
 - democracy problem – when to rely on a fair democratic process as the only way to arrive at a decision
- guidelines for appropriately allocating resources
 - the physician's primary obligation is to protect and promote the welfare and best interests of his or her patients
 - choose interventions known to be beneficial on the basis of evidence of effectiveness
 - seek the tests or treatments that will accomplish the diagnostic or therapeutic goal for the least cost
 - advocate for one's patients but avoid manipulating the system to gain unfair advantage for them
 - resolve conflicting claims for scarce resources justly, on the basis of morally relevant criteria such as need and benefit, using fair and publicly defensible procedures
 - inform patients of the impact of cost constraints on care, but in a sensitive way
 - seek resolution of unacceptable shortages at the level of hospital management or government

CPSO Policy Resource Allocation
Physicians should "recognize [their] responsibility to promote fair access to health care resources" and should "use health care resources prudently."

Research Ethics

Guiding Principles for Research Ethics

1. **Respect for persons**
(i.e. informed consent)
2. **Beneficence**
(i.e. balancing benefits and harms)
3. **Justice**
(i.e. avoiding exploitation or unjustified exclusion)

- involves the systematic analysis of ethical dilemmas arising during research involving human subjects to ensure that:
 - study participants are protected
 - clinical research is conducted to serve the interests of the participants and/or society as a whole
- major ethical dilemmas arise when a physician's obligation to the patient comes into conflict with other obligations and incentives
- any exceptions to disclosure for therapeutic consent do not apply in an experimental situation

Table 2. Ethical Principles for Research Involving Human Subjects

Patient's participation in research should not put him/her at a known or probable disadvantage with respect to medical care

Participant's voluntary and informed choice is usually required

Consent may not be required in special circumstances: chart reviews without patient contact; emergency situations for which there is no accepted or helpful standard of care and the proposed intervention is not likely to cause more harm than such patients already face

Access to the treatment that is considered standard

Placebo-controlled trials are generally acceptable where patients still receive the standard of care and are informed about the placebo arm and what that entails

Must employ a scientifically valid design to answer the research question

Scientific rigour ensured via peer review, expert opinion

Must demonstrate sufficient value to justify the risk posed to participants

Must be conducted honestly (i.e. carried out as stated in the approved protocol)

Findings must be reported promptly and accurately without exaggeration, to allow practicing clinicians to draw reasonable conclusions

Patients must not be enticed into risky research by the lure of money and investigators must not trade the interests of patients for disproportionate recompense by a sponsor; both participants and investigators are due fair recompense for their time and efforts

Any significant interventional trial ought to have a data safety monitoring board that is independent of the sponsor and can ensure safety of the ongoing trial

Laid out in the Declaration of Helsinki, the Belmont Report, etc.

Informed Consent for Research

- The nature of informed consent differs in the contexts of research and clinical practice in that the potential research subject must be informed about:
 - Purpose of the study
 - Source of funding
 - Nature and relative probability of harms and benefits
 - Nature of the physician's participation including any compensation
- Proposals for research must be submitted to a research ethics board to be scientifically and ethically evaluated and approved.

Physician-Industry Relations

- health care delivery in Canada involves collaboration between physicians and the pharmaceutical and health supply industries in the areas of research, education, and clinical evaluation packages (e.g. product samples)
- physicians have a responsibility to ensure that their participation in such collaborative efforts is in keeping with their duties to their patients and society
- gifts or free products from the pharmaceutical industry are inappropriate
 - sponsorship for travel and fees for conference attendance may be accepted only where the physician is a conference presenter and not just in attendance
 - physicians receiving such sponsorship must disclose this at presentations or in written articles
- CMA and CPSO guidelines for ethically appropriate physician-industry relations
 - the primary goal should be the advancement of the health of Canadians
 - relationships should be guided by the *CMA Code of Ethics*
 - the physician's primary obligation is to the patient
 - physicians should avoid any self-interest in their prescribing and referral practices
 - physicians should always maintain professional autonomy, independence, and commitment to the scientific method
- the *AMA Code of Medical Ethics* has a number of opinions on "Practice Matters" including "Industry representatives in clinical settings," "Financial incentives and the practice of medicine," and "Gifts to physicians from industry," (see www.ama-assn.org/ama/pub/physician-resources/medical-ethics/code-medical-ethics.shtml)

Doctor-Patient Relationship

- a partnership based on the physician providing expert opinion, information, options, and interventions that allows the patient to make informed choices about their health care
- within this relationship, the doctor and patient share the goals of positive health outcomes, good communication, honesty, flexibility, sensitivity, informed consent, and respect
- this relationship has the potential to be unequal due to a power difference
 - patients are ill and lack medical knowledge
 - physicians possess medical knowledge and skills and have their patients' trust

- due to the nature of the doctor-patient relationship, the physician will:
 - place the best interests of the patient first
 - establish a relationship of trust with the patient
 - follow through on undertakings made to the patient in good faith
- the physician will accept or refuse patients requesting care:
 - without consideration of race, gender, age, sexual orientation, financial means, religion or nationality
 - without arbitrary exclusion of any particular group of patients, such as those known to be difficult or afflicted with serious disease
 - except in emergency situations, in which case care must be rendered
- once having accepted a patient into care, the physician may terminate the relationship providing:
 - it is not an emergency
 - care has been transferred
 - adequate notice has been given to allow the patient to make alternative arrangements
 - they have other options to find 'medically necessary care'
- the physician will not exploit the doctor-patient relationship for personal advantage – financial, academic or otherwise
- the physician will disclose limitations to the patient where personal beliefs or inclinations limit the treatment the physician is able to offer
- the physician will maintain and respect professional boundaries at all times
 - including physical, emotional, and sexual boundaries
 - regarding treatment of themselves, their families, and friends

CPSO Policy: Treating Self and Family Members

Physicians will not diagnose or treat themselves or family members except for minor conditions or in emergencies and then only if no other physician is readily available.

CPSO Policy: Ending the Physician-Patient Relationship

Discontinuing services that are needed is an act of professional misconduct unless done by patient request, alternative services are arranged, or adequate notice has been given.

Personal and Professional Conduct

CanMEDS Competencies

- a framework of professional competencies established by the Medical Council of Canada (MCC) as objectives for the Medical Council of Canada Qualifying Exam (MCCQE)
- further information on MCC objectives can be found at www.mcc.ca

1. Communicator; Culturally Aware

- display sensitivity to people of all ages, races, cultures, religions, sexual orientations, and genders
- accept or refuse patients without consideration of age, race, culture, religion, sexual orientation, and gender
- understand the variation in values and morals and their impact on approaches to care and decision-making
- elicit patients' beliefs, concerns, and expectations about their illness
- conduct patient-centered interviews, ensure patient comprehension

2. Collaborator

- respect all members of the health care team
- identify the roles and competencies of each member, and delegate tasks appropriately
- consult other physicians and health care professionals effectively and appropriately
- consult with patients and families regarding continuing care plans
- be able to outline co-ordination of services (e.g. Public Health, Home Care, Social Services, Workers' Compensation, Children's Aid Society, etc.)

3. Health Advocate

- identify determinants of health:
 - biological (e.g. genes, impact of lifestyle)
 - physical (e.g. food, shelter, working conditions)
 - social (education, employment, culture, access to care)
- influence public health and health policy to protect, maintain, and promote the health of individuals and the community

4. Manager

- meet regulatory requirements in an office practice (e.g. medical record-keeping, narcotic control, infection control, etc.)
- be prudent in utilization of health care resources, based on anticipated cost-benefit balance
- regulate work schedule such that time is available for continuing education

5. Professional

- maintain standards of excellence in clinical care and ethical conduct
- exhibit appropriate personal and interpersonal behaviour
- enhance clinical competence through lifelong learning
- accept responsibility for personal actions
- do not exploit the physician-patient relationship for personal advantage (e.g. financial, academic)

6. Scholar

- commitment to critical appraisal, constructive skepticism
- participate in the learning of peers and others (e.g. students, health care professionals, patients)

Professional Considerations

Elderly Patient

- Identify their resuscitation options (CPR vs. DNR), if applicable
- Check for documentation of advance directives and POA where applicable
- For further details, see [Geriatric Medicine, GM11](#)

Pediatric Patient

- Identify the primary decision-maker (parents, guardian, wards-of-state, emancipated)
- Regarding capacity assessment see *Pediatric Aspects of Capacity Covered by the HCCA (ELOAM4)*
- Be wary of custody issues if applicable

Terminally Ill or Palliative Patient

- Consider the SPIKES approach to breaking bad news
- What are their goals of care, i.e. disease vs. symptom management?
- Identify advance directives, POA, or SDM, if applicable
- Check for documentation of resuscitation options (CPR vs. DNR) and likelihood of success
- For further details, see [Geriatric Medicine, GM11](#)

Incapable Patient

- If not already present, perform a formal capacity assessment
- Identify if the patient has a SDM or who has their POA
- Check the patient's chart for any Mental Health Forms (e.g. Form 1) or any forms they may have on their person (e.g. Form 42)

Areas of Controversy

Dealing with Controversial and Ethical Issues in Practice

- Discuss in a non-judgmental manner
- Ensure patients have full access to relevant and necessary information
- Identify if certain options lie outside of your moral boundaries and refer to another physician if appropriate
- Consult with appropriate ethics committees or boards
- Protect freedom of moral choice for students or trainees

Source: MCC-CLEO Objectives, 1998

Euthanasia: Ethically Appropriate Actions

- Respect competent decisions to forgo treatment
- Provide appropriate palliative measures
- Decline requests for euthanasia and assisted suicide

Euthanasia and Physician-Assisted Suicide

- **euthanasia**: a deliberate act undertaken by one person with the intention of ending the life of another person to relieve that person's suffering where the act is the cause of death
- **physician-assisted suicide**: the act of intentionally killing oneself with the assistance of a physician who deliberately provides the knowledge and/or the means
- ethical issues and arguments:
 - right to make autonomous choices about the time and manner of own death
 - belief that there is no ethical difference between the acts of euthanasia/assisted suicide and foregoing life-sustaining treatments
 - belief that these acts benefit terminally ill patients by relieving suffering
 - patient autonomy has limits
 - death should be the consequence of the morally justified withdrawal of life-sustaining treatments only in cases where there is a fatal underlying condition, and it is the condition (not the withdrawal of treatment) that causes death
- law
 - Canada: euthanasia and physician-assisted suicide are punishable offences under the Criminal Code of Canada
 - US: euthanasia is punishable under general homicide laws; Oregon and Washington are the only states to have enacted legislation allowing physicians to actively assist patients who wish to end their lives
- the use of palliative sedation with opioids in end-of-life care, knowing that death may occur as an unintended consequence (**principle of double effect**) is distinguished from euthanasia and assisted suicide where death is the primary intent
- the appropriate withdrawal of life-support is distinguished from euthanasia and assisted suicide as it is seen as allowing the underlying disease to take its 'natural course'

Maternal-Fetal Conflict of Rights

- conflict between maternal autonomy and the best interests of the fetus
- ethical issues and arguments
 - principle of reproductive freedom: women have the right to make their own reproductive choices
 - coercion of a woman to accept efforts to promote fetal well-being is an unacceptable infringement of her personal autonomy
- law: upholds a woman's right to life, liberty, and security of person and does not recognize fetal rights
 - if a woman is competent and refuses medical advice, her decision must be respected even if the fetus will suffer
 - the fetus does not have legal rights until it is born alive and with complete delivery from the body of the woman
- *Royal Commission on New Reproductive Technologies* recommendations:
 - medical treatment must never be imposed upon a competent pregnant woman against her wishes
 - no law should be used to confine a pregnant woman in the interest of her fetus
 - the conduct of a pregnant woman in relation to her fetus should not be criminalized
 - child welfare should never be used to control a woman's behaviour during pregnancy
 - civil liability should never be imposed upon a woman for harm done to her fetus during pregnancy
- ethically appropriate actions
 - a woman is permitted to refuse HIV testing during pregnancy, even if vertical transmission to fetus results
 - a woman is permitted to refuse Caesarean section in labour that is not progressing, despite evidence of fetal distress

Advanced Reproductive Technologies: Ethically Appropriate Actions

- Educate patients and address contributors to infertility (e.g. stress, alcohol, medications, etc.)
- Investigate and treat underlying health problems causing infertility
- Wait at least one year before initiating treatment with ART (exceptions – advanced age or specific indicators of infertility)
- Educate and prepare patients for potential negative outcomes of ART

Advanced Reproductive Technologies (ART)

- includes non-coital insemination, hormonal ovarian stimulation, and *in vitro* fertilization (IVF)
- ethical issues and arguments
 - donor anonymity vs. child-centred reproduction (i.e. knowledge about genetic medical history)
 - preimplantation genetic testing for diagnosis before pregnancy
 - lack of sufficient data regarding efficacy and complications to provide the full disclosure needed for truly informed consent
 - use of new techniques without patients appreciating their experimental nature
 - embryo status – the Supreme Court of Canada maintains that fetuses are “unique” but not persons under law; this view would likely apply to embryos as well
 - access to ART
 - ♦ private vs. public funding
 - ♦ social factors limiting access to ART (e.g. same-sex couples)
 - commercialization of reproduction; reimbursement of gamete donors is currently illegal in Canada

Fetal Tissue

- pluripotent stem cells have been derived from human embryonic and fetal tissue
- potential uses of stem cells in research:
 - studying human development and factors that direct cell specialization
 - evaluating drugs for efficacy and safety in human models
 - cell therapy: using stem cells grown *in vitro* to repair or replace degenerated/destroyed/malignant tissues (e.g. Parkinson's disease)
 - genetic treatment aimed at altering somatic cells (i.e. myocardial or immunological cells) is acceptable and ongoing
 - genetic treatment aimed at altering germ cells is prohibited in Canada and elsewhere
- *Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans* (Government of Canada, 2003)
 - embryo research is permitted up to 14 days post-fertilization
 - embryos created for reproductive purposes that are no longer required may be used
 - gamete providers must give free and informed consent for research use
 - no commercial transactions in the creation and use of the embryos is permitted
 - creation of embryos solely for research purposes is prohibited
 - human cloning is strictly prohibited
- risks of coercion must be minimized:
 - may not pressure fertility treatment team to generate more embryos than necessary
 - only discuss option of using fetal tissue for research after free and informed choice to have a therapeutic abortion has been made
 - physicians responsible for fertility treatment may not be part of a stem cell research team

The CMA remains neutral on the issue of embryonic stem cell research.

Abortion

- abortion: the active termination of a pregnancy before fetal viability
 - **fetal viability:** fetus >500 g, or >23-24 weeks gestational age
 - in the case of multiple pregnancy, selective termination of the non-viable or less viable fetus is allowed
- ethical and legal issues and arguments:
 - according to common law, the rights of a fetus are not equal to those of a human being
 - who should have input into the abortion decision (e.g. male partners, patient's guardians)
 - ♦ no law currently regulates abortion in Canada – it is a woman's medical decision to be made in consultation with whom she wishes; no mandatory role for spouse/family
- CMA policy on induced abortion:
 - induced abortion should not be used as an alternative to contraception
 - counselling on contraception must be readily available
 - full and immediate counselling services must be provided in the event of unwanted pregnancy
 - there should be no delay in the provision of abortion services
 - no patient should be compelled to have a pregnancy terminated
 - physicians should not be compelled to participate in abortion – if morally opposed, the physician should inform the patient so she may consult another physician
 - no discrimination should be directed towards either physicians who do not perform or assist at induced abortions or physicians who do
 - induced abortion should be uniformly available to all women in Canada and health care insurance should cover all the costs (N.B. the upper limit of gestational age for which coverage is provided varies between provinces)

Genetic Testing

- uses:
 - confirm a clinical diagnosis
 - detect genetic predisposition to a disease
 - ♦ allows preventative steps to be taken and helps patient prepare for the future
 - give parents the option to terminate a pregnancy or begin early treatment
- ethical dilemmas arise because of the nature of genetic information:
 - it has individual and familial implications
 - it pertains to future disease
 - it often identifies disorders for which there are no effective treatments or preventive steps
- ethical issues and arguments:
 - obtaining informed consent is difficult due to the complexity of genetic information
 - doctor's duty to maintain confidentiality vs. duty to warn family members
 - risk of social discrimination (e.g. insurance) and psychological harm
- law:
 - no current specific legislation exists
 - testing requires informed consent
 - no standard of care exists for clinical genetics but physicians are legally obligated to inform patients that prenatal testing exists and is available
 - breach of confidentiality – duty to warn family members
 - ♦ only acceptable if can likely prevent serious harm, such as if treatment or prevention is available (e.g. familial adenomatous polyposis)

Genetic Testing: Ethically Appropriate Actions

- Thorough discussion and realistic planning with patient before testing is done
- Genetic counselling for delivery of complex information, supportive discussion

Organization of Health Care in Canada

- one federal, three territorial, and ten provincial systems
- federal system provides care to Aboriginal groups, the RCMP, and the armed forces
- financed by both the public (70%) and private (30%) sectors
- each provincial plan must cover all medically necessary health services delivered in hospitals and by physicians; may choose to cover additional services such as home care and prescription drugs
- non-insured health services and fees are either covered by private insurance or by the individual
- workers' compensation funds cover treatment for work-related injuries and diseases

The current legal foundation of the Canadian health system is based on three statutes:

1. **Constitution Act** (1867) – deals primarily with the jurisdictional power between federal and provincial governments
2. **Canada Health Act** (1984) – outlines the national terms and conditions
3. **Canada Health and Social Transfer Act** (1996) – sets the conditions for fiscal transfers from the federal government to the provinces and territories

History

- 1867 *British North America Act* (now *Constitution Act*) establishes Canada as a confederacy
 - government has minimal role in health care at this time
 - “establishment, maintenance, and management of hospitals” under provincial jurisdiction
- 1947 Saskatchewan introduces universal hospital insurance
 - based on taxes and premiums
 - other provinces follow
- 1957 Federal government passes *Hospital Insurance and Diagnostic Services Act*
 - provinces with universal hospital insurance receives federal funds
 - federal government pays for approximately 50% of insured services
- 1962 Saskatchewan implements universal medical care insurance
 - physician services included
- 1965 *Royal Commission on Health Services (Hall Commission)* recommends federal leadership and financial support with provincial government operation
- 1966 **Medical Care Act** passed by federal government
 - federal government contribution maintained at 50% on average, with poorer provinces receiving more funds
 - medical insurance must be
 - Comprehensive ▪Portable
 - Universal▪Publicly administered
- 1977 *Established Programs Financing Act* passed by federal government
 - federal government gives “tax points” to provinces by reducing federal taxes and allowing provinces to collect more
 - funding no longer tied to direct services → federal influence wanes
 - provinces bear greater costs and impose restrictions on physicians
 - physicians respond with “extra-billing:” patients pay a supplementary fee
- 1984 **Canada Health Act** passed by federal government
 - replaced *Medical Care Act* and *Hospital Insurance and Diagnostic Services Act*
 - extra-billing banned by new fifth criterion: **Accessibility**
- 1996 *Canada Health and Social Transfer Act* passed by federal government
 - federal government gives provinces a single grant for health care, social programs, and post-secondary education; division of resources at provinces' discretion
- 1999 *Social Union Framework Agreement* signed by the Prime Minister and all Premiers and territorial leaders except Quebec
 - federal and provincial/territorial governments vow to concentrate their efforts to modernize Canadian social policy
- 2001 *Kirby and Romanow Commissions* appointed
 - Kirby Commission* (final report, October 2002)
 - one-member committee of the Senate: examined history of health care system in Canada, pressures and constraints of current health care system, role of federal government, and health care systems in foreign jurisdictions
 - Romanow Commission* (final report, November 2002)
 - one-member royal commission (former Saskatchewan Premier Roy Romanow) appointed by the Prime Minister to inquire into and undertake dialogue with Canadians on the future of Canada's public health care system

- 2003 *First Ministers' Accord on Health Care Renewal* signed
- First Ministers agreed on an action plan to improve access to quality care for all Canadians and to prepare an annual public report on primary and home care
 - 1st Health Council (composed of government and expert/public representatives) appointed to improve accountability in the health care system
- 2004 *First Ministers' Meeting on the Future of Health Care* produces a 10-year plan
- priorities include reductions in waiting times, development of a national pharmacare plan, and primary care reform
- 2005 *Chaoulli v. Quebec*, Supreme Court of Canada Decision
- ruled that banning private insurance is unconstitutional under the Quebec Charter of Rights, given that patients do not have access to those services under the public system in a timely way

Key Principles of the *Canada Health Act*

1. Public Administration

- provincial health care programs must be administered by public authorities

2. Comprehensiveness

- provincial health care programs must cover all necessary diagnostic, physician, and hospital services

3. Universality

- all eligible residents must be entitled to health care services

4. Portability

- emergency health services must be available to Canadians who are outside their home province, paid for by the home province

5. Accessibility

- user fees, charges, or other obstructions to insured health care services are not permitted

The federal government can reduce its contributions to provinces that violate the key principles of the *Canada Health Act*.

Health Care Expenditure and Delivery in Canada

- projected total health care expenditure in 2006 was \$148 billion, 10.0% of the GDP, approx. \$3678 USD per capita; this includes out-of-pocket, government-funded and third-party expenditures (*Canadian Institute of Health Information*)
- the 2006 Canadian health care expenditure increased 5.8% over 2005 spending (*Canadian Institute of Health Information*)
- the 2006 Canadian health care expenditure as a percentage of GDP ranked eighth out of 30 Organization for Economic Cooperation and Development (OECD) member nations
- 70.4% of health care spending came from public sector sources in 2006, as compared to 45.8% in the US
- in 2006 there were 2.1 physicians per 1000 population, ranking 26th out of OECD member countries

Payments for Care at Private For-Profit and Private Not-for-Profit Hospitals:

A Systematic Review and Meta-analysis

CMAJ 2004; 170(12):1817-24

Meta-analysis of 8 US observational studies involving more than 350 000 patients. Concluded that care provided by private for-profit hospitals was more expensive (Relative payments for care=1.19; 95% CI=1.07-1.33; p=0.001). If half of Canadian hospitals were converted to private for-profit institutions, an extra \$3.6 billion would be paid annually.

Delivery of Health Care

- hospital services in Canada are publicly funded but delivered through private, not-for-profit institutions owned and operated by communities, religious organizations, and regional health authorities
- this differs from other countries, such as the US (a mix of public and private funding, as well as private-for-profit and private not-for-profit delivery) and the UK (primarily public funding and delivery)

Figure 3. Canadian Health Care Dollars by Source of Funds, 2007

Source: Canadian Institute for Health Information, *National Health Expenditure Trends, 1975 to 2009*

Role of the Provincial Licensing Authorities

- the medical profession in Canada self-regulates under the authority of provincial legislation; Canada is the only country in the world where the medical profession still regulates itself
- physicians in each province are self-regulated by a licensing authority (see *Role of Professional Associations*); membership is **mandatory** to practice in that province
- system of self-regulation is based on the premise that the licensing authority must act first and foremost in the interest of the public
- Licensing Authority functions include
 - issuing non-transferable licenses allow doctors to practice only in that province
 - maintaining ethical, legal, and competency standards and developing policies to guide doctors
 - investigating complaints against doctors
 - disciplining doctors guilty of professional misconduct or incompetence (in most Canadian jurisdictions there is zero tolerance for sexual misconduct by physicians, resulting in harsh penalties including permanent suspension from the profession)

Distinction Between Licensure and Certification

- provincial licensing authorities provide non-transferable licensure to physicians
- the *Medical Council of Canada* (MCC) certifies physicians
 - certification is known as the Licentiate of the MCC (LMCC)
 - LMCC is acquired by passing the MCC Qualifying Examination Parts I and II
- the *Royal College of Physicians and Surgeons of Canada* (RCPSC) certifies specialists who complete an accredited residency program and pass the appropriate exam
 - voluntary membership of RCPSC is designated FRCPC or FRCSC (Fellow of the Royal College of Physicians/Surgeons of Canada)
- the *College of Family Physicians of Canada* (CFPC) certifies family physicians who complete an accredited residency program and pass the Certification Examination in Family Medicine
- the RCPSC and CFPC are responsible for monitoring ongoing continuing medical education (CME) and professional development

Certification by the LMCC plus either the RCPSC or CFPC is a minimum requirement for licensure by most provincial licensing authorities.

Role of Professional Associations

- provincial medical associations represent the economic and professional interests of doctors; membership is voluntary, although fee payment is mandatory in some provinces
- the *Canadian Medical Association* (CMA) is a national association that provides leadership to doctors and advocates for access to high quality health care in Canada; membership is voluntary and requires provincial medical association membership
- the CMA represents physicians' concerns at the national level, while the provincial medical associations negotiate fee and benefit schedules with provincial governments
- medical residents are represented nationally by the *Canadian Association of Interns and Residents*, and provincially by *Provincial Housestaff Organizations*, which uphold the economic and professional interests of residents
- medical students are represented at their universities by student societies; these bodies collectively form the *Canadian Federation of Medical Students*; francophone medical schools participate in the *Federation of Quebec Medical Student Societies*
- the *Canadian Medical Protective Association* (CMPA), a physician-run organization, is a voluntary insurance association that protects the integrity of member physicians by providing legal defense against allegations of malpractice or negligence and by providing risk management and educational programs, and general advice

The US Health Care System

- the United States health care system is market-based
- it is funded and delivered by a mixture of the public, private, and voluntary sectors; private-for-profit is the prevailing method of delivery
- public funding is derived from taxes raised at both the federal and state government levels

Health Care Expenditure and Delivery in the US

- health care spending in the US represents a large economic sector
 - health care comprises over 15% of the gross domestic product (GDP) (highest in the OECD), amounting to \$6714 USD per capita in 2006
 - one advantage is the widespread availability of technology – the US has 4 times as many MRI machines per capita than Canada
- the US scores poorly on some indicators of population health, with a life expectancy below the OECD average and infant mortality above the OECD average. Possible factors that account for this discrepancy are:
 - poor health of large uninsured population
 - high cost of health care administration
 - the provision of inefficient high-cost, high-intensity care
 - the higher-spending regions in the US do not provide any better quality of care, access to care, health outcomes or satisfaction with care when compared to the lower-spending regions
- the US has the highest level of obesity of all OECD nations at 34.3%; this has major implications for future health care spending

Cost of Health Care Administration in the United States and Canada

NEJM 2003; 349:768-75

Administrative costs were estimated from data on insurance overhead, employers' costs to manage benefits, and the administrative costs of hospitals, practitioners' offices, nursing homes, and home care. In 1999, the cost of U.S. health administration was \$1,059 per capita, more than three times greater than the cost in Canada (\$307 per capita).

Figure 5. Personal Health Care Expenditure in USA by Type, 2007

Source: National Center for Health Statistics. *Health, United States, 2009: With Special Feature on Medical Technology*. Hyattsville, MD. 2010.

Access to Health Services

- 70% of Americans under the age of 65 have private health insurance, either employer-sponsored or individually purchased; 12% receive health care through public health insurance; 18%, mainly the poor, have no health insurance
- access to publicly funded health services occurs primarily through two programs, Medicare and Medicaid (see Table 3), which were created by the 1965 *Social Security Act*
- other federal government-funded health programs include the Military Health Services System, the Veterans Affairs Health Services System, the Indian Health Service, and the Prison Health Service

Table 3. Medicare and Medicaid Program Information

	Medicare	Medicaid
Eligibility	People over the age of 65 People with end stage renal disease People of any age meeting the Medicare definition of disability	People who receive funds through social assistance programs Pregnant women People with developmental disabilities Low-income children through the 1997 State Children's Health Insurance Program
Coverage	Basic "Part A" providing inpatient hospital care, home care, limited skilled nursing facility care, and hospice care Supplemental "Part B" covers outpatient physician and clinic services, and requires payment of a further monthly fee	Basic coverage involves inpatient and outpatient hospital care, laboratory and x-ray services, skilled nursing care, home care, physician services, dental services, and family planning Financing for Medicaid is provided jointly by the federal and state governments, and program details vary greatly between states
Co-payment	To help pay for out-of-pocket expenditures, and to cover many of the services not insured by Medicare, the majority of Medicare beneficiaries buy supplemental private health insurance	States may impose deductibles, coinsurance, or co-payments on some Medicaid recipients for certain services Medicaid is not health insurance – coverage is unreliable as improvement in an individual's financial status can lead to a loss of Medicaid eligibility

Source: Centers for Medicare and Medicaid Services; www.cms.gov

Health Care Reform

- *Patient Protection and Affordable Care Act* and the *Health Care and Education Reconciliation Act of 2010* are federal statutes signed into law in March 2010 that include a number of new healthcare provisions to be implemented over 8 years
 - expand Medicaid eligibility, provide subsidies for insurance premiums and incentives for businesses to provide health care benefits, prohibit denial of coverage/claims for pre-existing conditions, and establish health-insurance exchanges
 - costs are offset by a number of health care related taxes, including a tax penalty for citizens with no health insurance (low income persons are exempt)

Physician Responsibilities Regarding Death

- physicians are required by law to complete a medical certificate of death unless the coroner needs notification (see *Role of the Coroner*); failure to report death is a criminal offence

Role of the Coroner

Notify Coroner if Death Occurs due to:

- Violence, negligence, misconduct
- Pregnancy
- Sudden or unexpected causes
- Disease **NOT** treated
- Cause other than disease
- Suspicious circumstances

- *Coroner's Act* (specific to Ontario, similar in other provinces) requires physicians to notify a coroner or police officer if death occurs:
 - due to violence, negligence, misconduct, misadventure, or malpractice
 - during pregnancy or is attributable to pregnancy
 - suddenly and unexpectedly
 - from disease which was not treated by a legally qualified medical practitioner
 - from any cause other than disease
 - under suspicious circumstances
- coroner investigates these deaths, as well as deaths that occur in psychiatric institutions, jails, foster homes, nursing homes, hospitals to which a person was transferred from a facility, institution or home, etc.
- in consultation with forensic pathologists and other specialists, the coroner establishes:
 - the identity of the deceased
 - where and when the death occurred
 - the medical cause of death
 - the means of death (i.e. natural, accidental, suicide, homicide or undetermined)
- coroners do not make decisions regarding criminality or legal responsibility

Palliative and End-of-Life Care

- focus of care is comfort and respect for person nearing death and maximizing quality of life for patient, family, loved ones
- appropriate for any patient at any stage of a life-threatening illness
- may occur in a hospital, hospice, in the community or at home
- often an interdisciplinary team of caregivers
- addresses the medical, psychosocial, and spiritual dimensions of care

Anesthesia Basics

6 A's of General Anesthesia

1. Anesthesia
2. Anxiolysis
3. Amnesia
4. Areflexia (muscle relaxation not always required)
5. Autonomic Stability
6. Analgesia

Types of Anesthesia

- **general**
 - general anesthesia
 - total IV anesthesia (TIVA)
- **regional**
 - spinal, epidural
 - peripheral nerve block
 - IV regional
- **local**
 - local infiltration
 - topical
- **sedation**
 - monitored anesthesia care
- note that different types of anesthesia can be combined (e.g. general + regional)

Pre-Operative Assessment

- to identify the patient's medical and surgical issues; to allow for the arrangement of further investigations, consultations and treatments for patients not yet optimized; and to plan anesthetic techniques

History and Physical

History

- indication for surgery
- surgical/anesthetic Hx: previous anesthetics/complications, previous intubations, medications, drug allergies
- PMHx
 - CNS: seizures, stroke, raised intracranial pressure (ICP), spinal disease
 - CVS: coronary artery disease (CAD), myocardial infarction (MI), congestive heart failure (CHF), hypertension (HTN), valvular disease, dysrhythmias, peripheral vascular disease (PVD), conditions requiring endocarditis prophylaxis, exercise tolerance, CCS class, NYHA class (see Cardiology and Cardiovascular Surgery, C33 for NYHA classification)
 - respiratory: smoking, asthma, chronic obstructive pulmonary disease (COPD), recent upper respiratory tract infection (URTI), sleep apnea
 - GI: gastroesophageal reflux disease (GERD), liver disease
 - renal: insufficiency, dialysis, CKD
 - hematologic: anemia, coagulopathies, blood dyscrasias
 - MSK: conditions associated with difficult intubations – arthritides (e.g. rheumatoid arthritis), cervical tumours, cervical infections/abscess, trauma to cervical spine, Down syndrome, scleroderma, obesity, conditions affecting neuromuscular junction (e.g. myasthenia gravis)
 - endocrine: diabetes, thyroid, adrenal disorders
 - other: morbid obesity, pregnancy, ethanol/other drug use
- FHx: malignant hyperthermia, atypical cholinesterase (pseudocholinesterase), other abnormal drug/anesthetic reactions

Physical Examination

- oropharynx and airway assessment to determine the likelihood of difficult intubation
- ability to assume “sniffing position” – upper cervical spine extension, lower cervical spine flexion (assesses likelihood of difficult intubation)
- no single test is specific or sensitive – all aid in determining the ease of intubation
 - Mallampati Classification (Figure 1)
 - thyromental distance (the distance of the lower mandible in the midline from the mentum to the thyroid notch)
 - ♦ with the adult patient's neck fully extended, <3 finger breadths (<6 cm) is associated with difficult intubation

- mouth opening (<2 finger breadths is associated with difficult intubation)
- tongue size
- dentition, dental appliances/prosthetic caps – must inform patients of the rare possibility of damage
- nasal passage patency (if planning nasotracheal intubation)
- bony landmarks and suitability of anatomy for regional anesthesia (if relevant)
- focused physical exam of the CNS, CVS, and respiratory systems
- general assessment of nutrition, hydration, and mental status
- pre-existing motor and sensory deficits
- sites for IV, central venous pressure (CVP), and pulmonary artery (PA) catheters

Figure 1. Mallampati Classification of Upper Airway Visualization

Pre-Operative Investigations

Table 1. Suggested Indications for Specific Investigations in the Pre-Operative Period

Test	Indications
CBC	Major surgery requiring group and screen or cross and match; chronic cardiovascular, pulmonary, renal, or hepatic disease; malignancy; known or suspected anemia; bleeding diathesis or myelosuppression in patient less than 1 year of age
Sickle cell screen	Genetically predisposed patient (hemoglobin electrophoresis if screen is positive)
INR, aPTT	Anticoagulant therapy, bleeding diathesis, liver disease
Electrolytes and Creatinine	Hypertension, renal disease, diabetes, pituitary or adrenal disease; digoxin or diuretic therapy, or other drug therapies affecting electrolytes; age >50
Fasting glucose level	Diabetes (repeat on day of surgery)
Pregnancy (beta-HCG)	Women of childbearing age
ECG	Heart disease, hypertension, diabetes, other cardiac risk factors (may include age), subarachnoid hemorrhage, CVA, head trauma, age (male >40 y.o., female >50 y.o.)
Echocardiogram	CHF, cardiomyopathy, valvular pathology, limited cardiac reserve, stroke of unknown etiology
Chest radiograph	Cardiac or pulmonary disease, malignancy, age >60

Guidelines to the Practice of Anesthesia, Revised 2006. Supplement to the Canadian Journal of Anesthesia, Vol 53(12), Dec. 2006. Reproduced with permission © Canadian Anesthesiologists' Society.

Fasting Guidelines

Fasting Guidelines Prior to Surgery (Canadian Anesthesiologists' Society)

- **8 hours** after a meal that includes meat, fried or fatty foods
- **6 hours** after a light meal (such as toast, crackers and clear fluid) or after ingestion of infant formula or nonhuman milk
- **4 hours** after ingestion of breast milk or jello
- **2 hours** after clear fluids (water, black coffee, tea, carbonated beverages, juice without pulp)

Impact of Anesthesia Management Characteristics on Severe Morbidity and Mortality

Anesthesiology 2005; 102(2):257-258

Study: Case-control study of patients undergoing anesthesia.

Patients: 803 cases and 883 controls were analyzed among a cohort of 869,483 patients undergoing anesthesia between 1995-1997. Cases were defined as patients who either remained comatose or died within 24 hours of receiving anesthesia. Controls were defined as patients who neither remained comatose nor died within 24 hours of receiving anesthesia.

Intervention: General, regional, or combined anesthesia to patients undergoing a surgical procedure.

Main Outcome: coma or death within 24 hours of receiving anesthesia

Results: The incidence of 24-hour postoperative death was 8.8 per 10,000 anesthetics (95% CI, 8.2-9.5) and the incidence of coma was 0.5 (95% CI, 0.3-0.6). Anesthesia management risk factors that were associated with a decreased risk of morbidity and mortality were: equipment check with protocol and documentation, directly available anesthesiologist with no change during anesthesia, 2 persons present at emergence of anesthesia, reversal of muscle relaxation, and postoperative pain medication.

American Society of Anesthesiology (ASA) Classification

- common classification of physical status at the time of surgery
- a gross predictor of overall outcome, NOT used as stratification for anesthetic risk (mortality rates)
- **ASA 1:** a healthy, fit patient
- **ASA 2:** a patient with mild systemic disease, e.g. controlled Type 2 diabetes, controlled essential HTN, obesity, smoker
- **ASA 3:** a patient with severe systemic disease that limits activity, e.g. stable CAD, COPD, DM, obesity
- **ASA 4:** a patient with incapacitating disease that is a constant threat to life, e.g. unstable CAD, renal failure, acute respiratory failure
- **ASA 5:** a moribund patient not expected to survive 24 hours without surgery, e.g. ruptured abdominal aortic aneurysm (AAA), head trauma with increased ICP
- for emergency operations, add the letter E after classification (e.g. ASA 3E)

Pre-Operative Optimization

- in general, any fluid and/or electrolyte imbalance should be corrected prior to elective surgery

Medications

- pay particular attention to cardiac and respiratory meds, narcotics and drugs with many side effects and interactions
- **pre-operative medications to start**
- prophylaxis
 - risk of GE reflux: sodium citrate 30 mL PO or ranitidine 150-300 mg PO 30 min to 1 hour pre-op
 - risk of infective endocarditis, GI/GU interventions: antibiotics
 - risk of adrenal suppression: steroid coverage
 - risk of DVT: heparin SC
 - consider oral benzodiazepines for the anxious patient
- optimization of co-existing disease: bronchodilators (COPD, asthma), nitroglycerin and beta-blockers (CAD risk factors)
- **pre-operative medications to stop**
 - oral hypoglycemics: stop on morning of surgery
 - antidepressants (tricyclics, MAOIs): stop on morning of surgery
- **pre-operative medication to adjust**
 - insulin, prednisone, coumadin, bronchodilators

Hypertension

- mild to moderate HTN is not an independent risk factor for peri-operative cardiovascular complications (*Lette et al. Ann. Surg.* 1992; 216:192-204)
- target sBP <180 mmHg, dBP <110 mmHg
- assess for absence/presence of end-organ damage and treat accordingly

Coronary Artery Disease (CAD)

- ACC/AHA Guidelines (2007) recommend postponing elective surgery 4-6 weeks following an MI
- this period carries an increased risk of reinfarction/death
 - <3 months after MI – 37% patients may reinfarct
 - 3-6 months after MI – 15%
 - >6 months after MI – risk remains constant at 5%
- if operative procedure is essential, and cannot be delayed, invasive intra and post-operative ICU monitoring reduces the risk to 6%, 2% and 1% respectively for the above time periods
- mortality with peri-operative MI is 20-50%
- initiation of peri-operative beta-blockade in patients with increased risk of CVA
 - beta-blockade should be continued if already started
 - initiate beta-blockade if inducible ischemia, CAD or multiple cardiac risk factors and undergoing high risk surgery
 - consider initiating beta-blockade if CAD or multiple cardiac risk factors and undergoing intermediate risk surgery
 - treatment with beta-blockers should be optimized well in advance of any surgery

Risk Assessment

1. Reconcile patient factors with surgical needs and devise a safe and effective anesthetic plan
2. Optimize co-morbidities

Effects of Extended-release Metoprolol Succinate in Patients Undergoing Non-Cardiac Surgery (POISE trial): A Randomised Controlled Trial.

Lancet 2008; 371:1839-47

Purpose: To investigate the role of beta-blockers (metoprolol) peri-operatively in patients with known vascular disease, undergoing non-cardiac surgery.

Methods: Patients from 190 centres in 23 countries were eligible if they were >45, undergoing non-cardiac surgery and were known to have significant vascular disease. Patients were randomised to either the metoprolol group or placebo. Participants received metoprolol (or placebo) 100 mg 2.4 hours before surgery and again 6 hours after surgery and following that 200 mg daily for 30 days. The primary endpoint was a composite of cardiovascular death, non-fatal myocardial infarction and non-fatal cardiac arrest. Analyses was by intention to treat.

Results: 8351 patients were recruited into the study, with 8331 completing the 30 day course. Use of metoprolol was found to significantly reduce the risk of cardiovascular death, non-fatal MI or non-fatal cardiac arrest vs. placebo (hazard ratio 0.84, $p < 0.05$) but significantly increased the rate of stroke (hazard ratio 2.17, $p < 0.01$) and overall risk of death (hazard ratio 1.33, $P < 0.05$).

Conclusion: Use of peri-operative beta-blockers (metoprolol) in patients with known vascular disease provides both risks and benefits, and these must be considered for each patient individually.

Endocrine Disorders

- diabetes mellitus
 - hypoglycemia
 - ♦ caused by drugs and surgical stresses and masked by anesthesia
 - ♦ prevent with dextrose/insulin infusion and blood glucose monitoring
 - end organ damage: be aware of damage to CVS, renal and nervous systems, including autonomic neuropathy
- hyperthyroidism
 - can experience sudden release of thyroid hormone (thyroid storm)
 - treatment: beta-blockers + pre-op prophylaxis
- adrenocortical insufficiency e.g. Addison's, exogenous steroid use
 - steroid coverage suggested if steroid use of >1 week in past 6 months

Respiratory Diseases

- asthma
 - bronchospasm from intubation, delivery of inhaled anesthetics
 - pre-op inhaled salbutamol may mitigate risk
 - avoid non-selective beta-blockers, caution with beta2 specific
 - cancel/delay elective surgery for poorly controlled asthma
- smoking
 - adverse effects: altered mucus secretion and clearance, decreased small airway caliber and altered immune response
 - abstain at least 8 weeks pre-op, if possible
 - if unable, abstaining even 24 hours pre-op has shown benefit
- COPD
 - anesthesia, surgery and analgesia predispose to atelectasis, bronchospasm, pneumonia, prolonged mechanical ventilation and respiratory failure
 - cancel/delay elective surgery for acute exacerbation
 - optimize with bronchodilators ± inhaled corticosteroids ± antibiotics

Aspiration

- risk of aspiration in gastroesophageal (GE) sphincter incompetency, GERD or hiatus hernia
- avoid inhibiting airway reflexes; reduce gastric volume and acidity
- employ rapid sequence induction if increased risk (see RSI, A9)
- increased risk with laryngeal mask (instead of ETT)

Monitoring

Canadian Guidelines to the Practice of Anesthesia and Patient Monitoring

- an anesthetist present: "the only indispensable monitor"
- a completed pre-anesthetic checklist: including ASA class, NPO policy, Hx and investigations
- a peri-operative anesthetic record: HR and BP q5min, dose and route of drugs and fluids
- continuous monitoring:
 - oxygenation
 - ventilation
 - circulation
 - temperature

Routine Monitors for All Cases

- **BP cuff, telemetry, pulse oximeter** (O₂ saturation), stethoscope, temperature probe, gas analyzer, capnometer (end tidal CO₂ to assess adequacy of ventilation)

Elements to Monitor (Figure 2)

- anesthetic depth
 - inadequate: blink reflex present when eyelashes lightly touched, HTN, tachycardia, tearing or sweating
 - excessive: hypotension, bradycardia
- oxygenation: pulse oximetry, inspired O₂ concentration (FiO₂)
- ventilation: verification of correctly positioned ETT, chest excursions, breath sounds, end tidal CO₂ analysis, end tidal inhaled anesthesia analysis
- circulation: pulse, heart sounds, BP, telemetry, oximetry, central venous pressure (CVP), pulmonary capillary wedge pressure
- temperature: temperature probe

Pre-Anesthetic Checklist

SAMMM

Suction – connected and working
Airways – laryngoscope and blades, ETT, syringe, stylet, oral and nasal airways, tape, bag and mask
Machine – connected, pressures okay, all meters functioning, vaporizers full
Monitors – available, connected and working
Medications – IV fluids and kit ready, emergency medicines in correct location and accessible

Figure 2. Typical Anesthesia Monitor

Induction Agents

- induction may be achieved with intravenous agents, volatile agents or both

Intravenous Agents

- Table 11, A25
- the IV induction agents include a selection of non-opioid drugs used to provide amnesia and blunt reflexes. These are initially used to draw the patient into the maintenance phase of general anesthesia rapidly, smoothly, and with little adverse effects
 - e.g. propofol, sodium thiopental or ketamine
 - propofol and ketamine are also used for the maintenance phase of GA

Volatile Inhalational Agents

- Table 13, A26
- general concepts of volatile agents are discussed below
 - e.g. sevoflurane, desflurane, isoflurane, enflurane, halothane and nitrous oxide

MAC (minimum alveolar concentration)

- definition: the alveolar concentration of an agent at one atmosphere (atm) of pressure that will prevent movement in 50% of patients in response to a surgical stimulus (e.g. abdominal incision)
- often 1.2-1.3 times MAC will ablate response in the general population
- potency of inhalational agents is compared using MAC
- MAC values are roughly additive when mixing N₂O with another volatile agent (i.e. 0.5 MAC of a potent agent + 0.5 MAC of N₂O = 1 MAC of potent agent; however, this only applies to movement, not other effects such as blood pressure changes and does not hold over the entire N₂O dose range)
- MAC-intubation: the MAC of anesthetic that will inhibit movement and coughing during endotracheal intubation, generally 1.3 MAC
- MAC-block adrenergic response (MAC-BAR): the MAC necessary to blunt the sympathetic response to noxious stimuli, generally 1.5 MAC
- MAC-awake: the MAC of a given volatile anesthetic at which a patient will open their eyes to command, usually 0.3-0.4 of the usual MAC value

Determinants of Speed of Onset of Volatile Anesthetics

- Solubility:** decrease solubility, increase rate of induction
- Cardiac Output (CO):** as CO increases, anesthetic uptake to blood increases and alveolar gas concentration decreases, thus delaying induction
- Partial pressure difference between alveolar and venous blood:** increase gradient, decrease rate of induction
- Inspired Gas Concentration:** increase inspired concentration, increase rate of induction
- Alveolar Ventilation:** increase alveolar ventilation, increase rate of induction
- Second Gas Effect:** when 2 gases are administered together, uptake of the first gas (e.g. N₂O) increases the alveolar concentration of the second gas (e.g. desflurane), increase rate of induction

Solubility of Volatile Anesthetics in Blood Least soluble → Most soluble

Nitrous oxide < desflurane < sevoflurane < isoflurane < halothane

Muscle Relaxants and Reversing Agents

- depolarizing muscle relaxants: succinylcholine (SCh)
- non-depolarizing: rocuronium, mivacurium, vecuronium
- specific muscle relaxants are described in Tables 14 and 15

Figure 3. Anatomy and Physiology of the Neuromuscular Junction (NMJ)

Muscle Relaxants

- muscle relaxation produces the following desired effects:
 1. facilitates intubation
 2. assists with mechanical ventilation
 3. prevents muscle stretch reflex and decreases muscle tone
 4. allows access to the surgical field (intracavitary surgery)
- never use without adequate preparation and equipment to maintain airway and ventilation
- blocks nicotinic cholinergic receptors in NMJ
- provides skeletal muscle paralysis, including the diaphragm, but spares involuntary muscles such as the heart and smooth muscle
- nerve stimulator is used intraoperatively to assess the degree of nerve block; no twitch response seen with complete neuromuscular blockade

Reversing Agents for Non-Depolarizing Muscle Relaxants (e.g. neostigmine, pyridostigmine, edrophonium)

- reversal agents are acetylcholinesterase inhibitors
 - inhibits enzymatic degradation of ACh; increases amount of ACh at nicotinic and muscarinic receptors, displacing non-depolarizing muscle relaxant
- anticholinergic agents, such as atropine or glycopyrrolate, are simultaneously administered to minimize muscarinic effect of reversal agents (i.e. bradycardia, salivation and increased bowel peristalsis)

Plasma Cholinesterase

Plasma cholinesterase is produced by the liver and metabolizes SCh, ester local anesthetics, and mivacurium. A prolonged duration of blockade by SCh occurs with:

- (a) decreased quantity of plasma cholinesterase, e.g. liver disease, pregnancy, malignancy, malnutrition, collagen vascular disease, hypothyroidism.
- (b) abnormal quality of plasma cholinesterase, i.e. normal levels but impaired activity of enzymes, genetically inherited.

Airway Management

Airway Anatomy Review

- normal airway: nares → nasal cavities → nasal pharynx → laryngeal pharynx → trachea
- resistance to airflow through nasal passages accounts for approximately 2/3 of total airway resistance
- pharyngeal airway extends from posterior aspect of the nose to cricoid cartilage
- the glottic opening (triangular space formed between the true vocal cords) is the narrowest segment of the laryngeal opening in adults
- when intubating, the glottic opening is used as the space through which one visualizes proper placement of the endotracheal tube (ETT)
- the trachea begins at the level of the thyroid cartilage at the level of C6
- the trachea bifurcates into the right and left main bronchi at the level of T5

Figure 4. Landmarks for Intubation

Table 2. Methods of Supporting the Airway

	Bag and Mask	Laryngeal Mask Airway (LMA)	Endotracheal Tube (ETT)
Advantages/Indications	<ul style="list-style-type: none"> • Basic • Non-invasive • Readily available 	<ul style="list-style-type: none"> • Easy to insert • Less airway trauma/irritation than ETT • Frees up hands (vs. face mask) • Primarily used in spontaneously ventilating patient 	<p>"The 5 P's"</p> <ul style="list-style-type: none"> • Ensures airway Patency • Protects against aspiration • Allows Positive pressure ventilation • Allows suctioning i.e. "Pulmonary toilet" • A route for Pharmacological administration
Disadvantages/Contraindications	<ul style="list-style-type: none"> • Risk of aspiration if ↓ LOC • Cannot ensure airway patency • Inability to deliver precise tidal volume • Operator fatigue 	<ul style="list-style-type: none"> • Risk of gastric aspiration • PPV > 20 cm H₂O needed • Limited TMJ mobility • C-spine or laryngeal cartilage fracture • Oropharyngeal, retropharyngeal pathology or foreign body 	<ul style="list-style-type: none"> • Insertion can be difficult • Muscle relaxant usually needed • Laryngospasm may occur on failed intubation or extubation • Sympathetic stress due to intubation
Other	<ul style="list-style-type: none"> • Facilitate airway patency with jaw thrust and chin lift • Can use oropharyngeal/nasopharyngeal airway 	<ul style="list-style-type: none"> • Does NOT protect against laryngospasm or gastric aspiration • Sizing (approx): 40-50 kg: 3 50-70 kg: 4 70-100 kg: 5 	<ul style="list-style-type: none"> • Auscultate to avoid endobronchial intubation • Sizing (approx): Male: 8.0-9.0 mm Female: 7.0-8.0 mm Pediatric: (age/4) + 4 mm

Tracheal Intubation

Equipment for Intubation

- oxygen source and self-inflating bag
- face mask (appropriate size and one size larger and smaller)
- oropharyngeal and nasopharyngeal airways
- endotracheal tubes (appropriate size and one size smaller)
- tracheal stylet
- syringe for tube cuff inflation
- suction
- laryngoscopes

Preparing for Intubation

- failed attempts at intubation can make further attempts more difficult due to tissue trauma
- plan, prepare and assess for potential difficulties (see *Pre-operative Assessment*, A2)
- ensure equipment is available and working (e.g. test ETT cuff, check laryngoscope light, machine check)
- pre-oxygenate/denitrogenate: patient breathes 100% O₂ for 3-5 min or for 4 vital capacity breaths
- may need to suction mouth and pharynx first

Proper Positioning for Intubation

- "sniffing position": flexion of lower C-spine (C5,6), i.e. bow head forward and extension of upper C-spine at atlanto (C1)-occipital joint, i.e. nose in the air
- aligns the three axes of mouth, pharynx and larynx to allow visualization from the oral cavity to the glottis (Figure 5)
- proper position for laryngoscope tip to visualize cords is in the epiglottic vallecula
- contraindicated in known/suspected C-spine fracture/instability

Tube Insertion

- ETT insertion can incite a significant sympathetic response due to a "foreign body reflex" in the trachea, including: tachycardia, dysrhythmias, myocardial ischemia, increased BP and coughing
- a malpositioned ETT is a potential hazard for the intubated patient
 - if too deep, may result in right endobronchial intubation, which is associated with left-sided atelectasis and right-sided tension pneumothorax
 - if too shallow, may lead to accidental extubation, vocal cord trauma or laryngeal paralysis as a result of pressure injury by the ETT cuff
- the tip of ETT should be located at the midpoint of the trachea at least 2 cm above the carina and the proximal end of the cuff should be placed at least 2 cm below the vocal cords
 - approximately 20-23 cm mark at the right corner of the mouth for men and 19-21 cm for women

Figure 5. Anatomic Considerations in Laryngoscopy

A. neutral position, B. C-spine flexion, C. C-spine flexion with atlanto-occipital extension.

Confirmation of Tracheal Placement of ETT

- direct
 - visualization of ETT passing through cords
 - bronchoscopic visualization of ETT in trachea
- indirect
 - end-tidal CO₂ in exhaled gas measured by capnograph
 - auscultate for equal breath sounds bilaterally and absent breath sounds over epigastrium
 - chest movement and no abdominal distention
 - feel the normal compliance of lungs when ventilating patient
 - condensation of water vapour in ETT visible during exhalation
 - refilling of reservoir bag during exhalation
 - AP or lateral CXR: ETT tip at midpoint of thoracic inlet and carina (lateral CXR more sensitive and specific)

Complications During Laryngoscopy and Intubation

- mechanical
 - dental damage
 - laceration (lips, gums, tongue, pharynx, esophagus)
 - laryngeal trauma
 - esophageal or endobronchial intubation
 - accidental extubation
 - insufficient cuff inflation or cuff laceration: results in leaking and aspiration
- systemic
 - laryngospasm
 - bronchospasm
- esophageal intubation suspected when
 - end-tidal CO₂ zero or near zero on capnograph
 - abnormal sounds during assisted ventilation
 - impairment of chest excursion
 - hypoxia/cyanosis
 - presence of gastric contents in ETT
 - distention of stomach/epigastrium with ventilation

Intubation Tools

MD SOLES
Monitoring
Drugs
Suction
Oxygen
Laryngoscopes
ETT
Stylet, Syringe

Medications that can be given through the ETT

NAVEL
Naloxone
Atropine
Ventolin
Epinephrine
Lidocaine

Differential Diagnosis of Poor Bilateral Breath Sounds after Intubation

DOPE
Displaced ETT
Obstruction
Pneumothorax
Esophageal intubation

Rapid Sequence Induction (RSI)

- indicated when patient has “full stomach”, i.e. predisposed to regurgitation/aspiration:
 - decrease level of consciousness (LOC)
 - trauma
 - meal within 6 hours
 - sphincter incompetence suspected (GERD, hiatus hernia, nasogastric tube)
 - increased abdominal pressure (pregnancy, obesity, bowel obstruction, acute abdomen)
- pre-oxygenate/denitrogenate: patient breathes 100% O₂ for 3-5 minutes or for 4 vital capacity breaths prior to induction of anesthesia (do NOT bag ventilate)
- assistant performs Sellick's maneuver: pressure on cricoid cartilage to compress esophagus between cartilage and C6 to prevent reflux/aspiration
- administration of induction agent immediately followed by fast acting muscle relaxant (e.g. SCH)
- intubate shortly after administration of muscle relaxant (approximately 45-60 seconds) with no bag-mask ventilation in between induction and intubation
- must use cuffed ETT to prevent aspiration of gastric contents
- inflate cuff, verify correct placement of ETT, release cricoid cartilage pressure
- ventilate when ETT in place and cuff inflated

Difficult Airway

- difficulties with bag-mask ventilation, supraglottic airway, endotracheal intubation, infraglottic airway or surgical airway
- algorithms exist for difficult airways (e.g. *Anesthesiology* 2003; 98:3273, *Anaesthesia* 2004; 59:675)
- pre-op assessment (history of previous difficult airway, airway examination) and pre-oxygenation are important preventative measures
- if difficult airway expected, consider:
 - awake intubation
 - intubating with bronchoscope, trachlight (lighted stylet), fibre-optic laryngoscope, glidescope, etc.
- if intubation unsuccessful after induction:
 1. CALL FOR HELP
 2. ventilate with 100% O₂ via bag and mask
 3. consider returning to spontaneous ventilation and/or waking patient

Predicting Difficult Intubation in Apparently Normal Patients

Anesthesiology 2005; 103:429-37

Purpose: To assess widely available bedside tests and widely used laryngoscopic techniques in the prediction of difficult intubations.

Study: Meta-analysis.

Patients: 35 studies encompassing 50,760 patients.

Definitions: Difficult intubation was defined usually as Cormack-Lehane grade of 3 or greater, but some authors reported the requirement of a special technique, multiple unsuccessful attempts, or a combination of these as the accepted standard for difficult intubation.

Results: The overall incidence of difficult intubation was 5.8% (95% CI, 4.5–7.5%) for the overall patient population, 6.2% (95% CI, 4.6–8.3%) for normal patients excluding obstetric and obese patients, 3.1% (95% CI, 1.7–5.5%) for obstetric patients, and 15.8% (95% CI, 14.3–17.5%) for obese patients.

Mallampati score: SN: 49% SP:86% PLR:3.7 NLR:0.5, Thyromental distance: SN:20% SP:94% PLR:3.4 NLR:0.8 Sternomental distance: SN:62% SP:82% PLR:5.7 NLR:0.5, Mouth opening: SN:22% SP:97% PLR: 4.0 NLR:0.8, Wilson risk-sum: SN:46% SP:89% PLR:5.8 NLR:0.6, Combination Mallampati and thyromental distance: SN:36% SP:87% PLR:9.9 NLR:0.6

Conclusions: A combination of the Mallampati test and thyromental distance is the most accurate at predicting difficult intubation. The positive likelihood ratio (9.9) is supportive of the test as a good predictor of difficult intubation.

PLR: Positive likelihood ratio; NLR: Negative likelihood ratio; SN: Sensitivity; SP: Specificity

- if bag and mask ventilation inadequate:
 1. CALL FOR HELP
 2. attempt ventilation with oral airway
 3. consider/attempt LMA
 4. emergency invasive airway access (e.g. rigid bronchoscope, cricothyrotomy or tracheostomy)

Intraoperative Management

Oxygen Therapy

Figure 6. HbO₂ Saturation Curve

- in general the goal of oxygen therapy is to maintain oxygen saturation (SaO₂) >90%
- below an SaO₂ of 90%, a small decrease in saturation corresponds to a large drop in PaO₂ (Figure 6)
- in intubated patients, oxygen is delivered via the endotracheal tube (ETT)
- in patients not intubated, there are many oxygen delivery systems available; the choice depends on oxygen requirements (FiO₂) and the degree to which precise control of delivery is needed
- cyanosis can be detected at SaO₂ = 80%, frank cyanosis at SaO₂ = 67%

Low Flow Systems

- acceptable if tidal volume 300-700 ml, respiratory rate (RR) <25, consistent ventilation pattern
- provide O₂ at flows between 0-8 L/min
- dilution of oxygen with room air results in a decrease in the inspired oxygen concentration (FiO₂)
- an increase in minute ventilation (tidal volume x RR) results in a decrease in the inspire oxygen concentration
- e.g. **nasal canula (prong)**
 - well tolerated if flow rates <5-6 L/min, at high flows drying of nasal mucosa
 - the nasopharynx acts as an anatomic reservoir that collects O₂
 - the delivered oxygen concentration (FiO₂) can be estimated by adding 4% for every additional litre of O₂ delivered (e.g. at normal tidal volume and RR, flow rate of 1-6 L/min equate to FiO₂ of 24-44%)

Reservoir Systems

- use a volume reservoir to accumulate oxygen during exhalation thus increasing the amount of oxygen available for the next breath
- **simple face mask (Hudson face mask)**
 - covers patient's nose and mouth and provides an additional reservoir beyond nasopharynx
 - fed by small bore O₂ tubing at a rate of at least 6 L/min to ensure that exhaled CO₂ is flushed through the exhalation ports and not rebreathed
 - FiO₂ of 55% can be achieved at O₂ flow rates of 10 L/min
- **non-rebreather mask**
 - reservoir bag and a series of one-way valves direct gas flow from the bag on inhalation and allow release of expired gases on exhalation, thus allowing for oxygen accumulation during intubation
 - O₂ flow rates of 10-15 L/min are needed to maintain the reservoir bag inflation and should deliver FiO₂ >80%

High Flow Systems

- generates flows of up to 50-60 L/min
- meets/exceeds patient's inspiratory flow requirement
- delivers consistent and predictable concentration of O₂
- **Venturi mask**
 - delivers specific percentages of oxygen by varying the size of air entrainment
 - port determines the oxygen concentration (i.e. can vary to achieve 24%, 28%, 35%, 50%)
 - enables control of gas humidity
- **Puritan mask**
 - delivers the highest level of humidified oxygen

Ventilation

- in patients given muscle relaxants, ventilation is maintained with positive pressure ventilation (PPV)
- if no muscle relaxant is given patients may have sufficient spontaneous respirations to maintain ventilation, or assisted/controlled ventilation can be used

Alveolar O₂ Gas Equation

$$PAO_2 = FiO_2 (P_{atm} - P_{H_2O}) - PaCO_2$$

Arterial O₂ Content

$$CaO_2 = (SaO_2)(Hb)(1.34) + (PaO_2)(0.003)$$

CaO₂ = arterial O₂ content

SaO₂ = % hemoglobin saturation

PaO₂ = arterial O₂ pressure

- other indications of mechanical ventilation:
 - apnea
 - hypoventilation
 - intraoperative positioning limiting respiratory excursion (e.g. prone, Trendelenburg)
 - required hyperventilation (to lower intracranial pressure)
 - deliver positive end expiratory pressure (PEEP)
 - increased intrathoracic pressure (e.g. laparoscopic procedure)
- complications of mechanical ventilation:
 - decreased CO₂ due to hyperventilation
 - decreased BP due to decreased venous return from increased intrathoracic pressure
 - alkalemia with over correction of chronic hypercarbia
 - nosocomial pneumonia/bronchitis
- see Respirology, R27 for ventilatory modes

Table 3. Causes of Intraoperative Hyper- and Hypocapnea

Hypocapnea (↓ CO ₂)	Hypercapnea (↑ CO ₂)
Hyperventilation	Hypoventilation
Hypothermia	Hyperthermia
Decreased blood flow to lungs	Improved blood flow to lungs after resuscitation or hypotension
Incorrect placement of sampling catheter	Low bicarbonate
Inadequate sampling volume	Anesthetic breathing circuit error <ul style="list-style-type: none"> • Inadequate fresh gas flow • Rebreathing, faulty circuit absorber valves • Exhausted soda lime
Incipient pulmonary edema	
Air embolism	Water in capnography device

Temperature

Causes of Hypothermia (<36.0°C)

- intraoperative temperature losses are common (e.g. 90% of intraoperative heat loss is transcutaneous), due to:
 - OR environment (cold room, IV fluids, instruments)
 - open wound
- prevent with inflated warming blanket and warmed IV fluids (if giving platelet transfusion put through a line that does not go through warmer, warmer distorts viability of platelets)

Causes of Hyperthermia (>37.5-38.3°C)

- drugs (e.g. atropine)
- blood transfusion reaction
- infection/sepsis
- medical disorder (e.g. thyrotoxicosis)
- malignant hyperthermia (see *Uncommon Complications*, A24)
- over-zealous warming efforts

Heart Rate

Causes of Intraoperative Tachycardia

- confirm it is sinus tachycardia vs. other rhythms (e.g. atrial fibrillation/flutter, paroxysmal atrial tachycardia, accessory pathway syndromes, ventricular tachycardia)
- causes of sinus tachycardia:
 - shock/hypovolemia/blood loss
 - anxiety/pain/light anesthesia
 - full bladder
 - anemia
 - febrile illness/sepsis
 - drugs (e.g. atropine, cocaine, dopamine, epinephrine, ephedrine, isoflurane, isoproterenol, pancuronium)
 - Addisonian crisis, hypoglycemia, transfusion reaction, malignant hyperthermia

Causes of Intraoperative Bradycardia

- increased parasympathetic tone vs. decreased sympathetic tone
- **must** rule out hypoxemia
- arrhythmias (see Cardiology and Cardiovascular Surgery, C12)
- baroreceptor reflex due to increased intracranial pressure or increased blood pressure
- vagal reflex (occulocardiac reflex, carotid sinus reflex, airway manipulation)
- drugs (e.g. succinylcholine, opioids, edrophonium, neostigmine, halothane, digoxin, beta-blockers)
- high spinal/epidural anesthesia

Suspect difficult ventilation with:

BONES

Beard
Obesity/Obstetrics
No teeth
Elderly
Sleep apnea

Causes of Intraoperative Hypoxia

Inadequate oxygen supply: e.g. breathing system disconnection, obstructed or malpositioned ETT, leaks in the anesthetic machine, loss of oxygen supply.

Hypoventilation

Ventilation-perfusion inequalities: e.g. atelectasis, pneumonia, pulmonary edema, pneumothorax.

Reduction in oxygen carrying capacity: e.g. anemia, carbon monoxide poisoning, methemoglobinemia, hemoglobinopathy.

Leftward shift of the hemoglobin-oxygen saturation curve: e.g. hypothermia, decreased 2,3-DPG, alkalosis, hypocarbia, carbon monoxide poisoning.

Right-to-Left cardiac shunt

Hypothermia (32°-35.9°C)

Impact on Outcomes

Reduces resistance to wound infections by impairing immune function.

Increases the period of hospitalization by delaying healing.

Reduces platelet function and impairs activation of coagulation cascade increasing blood loss and transfusion requirements.

Triples the incidence of V-tach and morbid cardiac events.

Decreases the metabolism of anesthetic agents prolonging post-op recovery.

Blood Pressure

Intraoperative Shock

SHOCKED

Sepsis or Spinal shock
Hypovolemic/Hemorrhagic
Obstructive
Cardiogenic
anaphylactic
Extra/other
Drugs

Causes of Intraoperative Hypotension/Shock (sBP <90 mmHg or MAP <60 mmHg)

a) hypovolemic/hemorrhagic shock

- see Infectious Diseases, ID24
- most common form of shock, due to blood loss or dehydration
- class 1 hemorrhage: 0-15% of blood volume or <3% total body water (TBW)
 - ♦ decreased peripheral perfusion of organs able to withstand prolonged ischemia (skin, fat, muscle, bone)
 - ♦ patient feels cold, postural hypotension and tachycardia, cool/pale/moist skin, low JVP, decreased CVP, increased peripheral vascular resistance, concentrated urine
 - ♦ treatment: rapidly infuse 1-2 L of balanced salt solutions (BSS), then maintenance fluids
- class 2 hemorrhage: 15-30% of blood volume or approximately 6% of TBW
 - ♦ thirst, supine hypotension and tachycardia, oliguria or anuria
 - ♦ treatment: rapidly infuse 2 L of BSS then re-evaluate continued needs
- class 3 hemorrhage: 30-40% of blood volume
 - ♦ mildly decreased perfusion to heart and brain
 - ♦ marked tachypnea, tachycardia, decreased sBP, oliguria, confusion
 - ♦ treatment: rapidly infuse 2 L of BSS
 - ♦ replace blood losses with BSS (1:3) or PRBCs, colloid (1:1)
 - ♦ maintain urine output >0.5 mL/kg/hr
- class 4 hemorrhage: >40% of blood volume or approximately 9% of TBW
 - ♦ decreased perfusion of heart and brain
 - ♦ agitation, confusion, obtundation, supine hypotension and tachycardia, rapid deep breathing, anuria
 - ♦ treatment: same as class 3

b) obstructive shock

- obstruction of blood into or out of the heart
- increased JVP, distended neck veins, increased systemic vascular resistance, insufficient cardiac output (CO)
- e.g. tension pneumothorax, cardiac tamponade, pulmonary embolism

c) cardiogenic shock

- myocardial dysfunction
- increased JVP, distended neck veins, increased systemic vascular resistance, decreased CO
- e.g. dysrhythmias, ischemia/infarct, cardiomyopathy, acute valvular dysfunction

d) septic shock

- bacterial, viral, fungal, endotoxins/mediators cause vasodilation and capillary leakage
- associated with contamination of open wounds, intestinal injury or penetrating trauma
- fever, decreased JVP, wide pulse pressure, increased cardiac output, increased HR, decreased systemic vascular resistance \pm pressors
- initial treatment: antibiotics, volume expansion

e) spinal/neurogenic shock

- decreased sympathetic tone
- hypotension without tachycardia or peripheral vasoconstriction (warm skin)

f) anaphylactic shock

- see Emergency Medicine, ER30
- acute/subacute generalized allergic reaction due to an inappropriate or excessive immune response (type I hypersensitivity)
 - ♦ treatment
 - moderate reaction: generalized urticaria, angioedema, wheezing, tachycardia
 - epinephrine (1:1000) 0.3-0.5 mg SC
 - antihistamines: diphenhydramine (Benadryl®) 25-50 mg IM
 - salbutamol (Ventolin®) 1 cc via nebulizer
 - severe reaction/evolution: severe wheezing, laryngeal/pulmonary edema, shock
 - ABCs, may need ETT due to airway edema
 - epinephrine (1:1000) 0.1-0.3 mg IV (or via ETT if no IV access) to start, repeat as needed
 - antihistamines: Benadryl® 50 mg IV (~1 mg/kg)
 - steroids: hydrocortisone (Solucortef®) 100 mg IV (~1.5 mg/kg) or methylprednisolone (Solumedrol®) 1 mg/kg IV q6h x 24h
 - large volumes of crystalloid may be required

g) drugs

- vasodilators, high spinal anesthetic interfering with sympathetic outflow

h) other

- transfusion reaction, Addisonian crisis, thyrotoxicosis, hypothyroid, aortocaval syndrome

Causes of Intraoperative Hypertension

- pain, anxiety due to inadequate anesthesia
- pre-existing essential hypertension, coarctation or pre-eclampsia
- hypoxemia/hypercarbia
- hypervolemia
- drugs (e.g. ephedrine, epinephrine, cocaine, phenylephrine, ketamine)
- allergic/anaphylactic reaction
- hypermetabolic states: malignant hyperthermia, neuroleptic malignant syndrome (see [Psychiatry](#), PS44), pheochromocytoma, thyroid storm (see [Endocrinology](#), E35, E25)

Fluid Balance and Resuscitation

- TOTAL REQUIREMENT = MAINTENANCE + DEFICIT + ONGOING LOSS
- in surgical settings this formula must take into account multiple factors including pre-operative fasting/decreased fluid intake, increased losses during or before surgery, fluid shifting during surgery, fluids given with blood products and medications

What is the Maintenance?

- average healthy adult requires approximately 2500 mL water/day
 - 200 mL/day GI losses
 - 800 mL/day insensible losses (respiration, perspiration)
 - 1500 mL/day urine (beware of renal failure)
- increased requirements with fever, sweating, GI losses (vomiting, diarrhea, NG suction), adrenal insufficiency, hyperventilation, and polyuric renal disease
- decreased requirements with anuria/oliguria, SIADH, highly humidified atmospheres, and CHF
- 4:2:1 rule to calculate maintenance requirements (applies to crystalloids only)
 - 4 mL/kg/hour first 10 kg
 - 2 mL/kg/hour second 10 kg
 - 1 mL/kg/hour for remaining weight >20 kg
- maintenance electrolytes
 - Na: 3 mEq/kg/day
 - K: 1 mEq/kg/day
- e.g. 50 kg patient maintenance requirements
 - fluid = $40 + 20 + 30 = 90$ mL/hour = 2160 mL/day
 - Na = 150 mEq/day (therefore 66 mEq/L)
 - K = 100 mEq/day (therefore 22 mEq/L)
- above patient's requirements roughly met with 2/3 D5W, 1/3 NS
 - e.g. 2/3 + 1/3 @ 100 mL/hour with 20 mEq KCl per litre

Figure 7. Total Body Water Division in a 70 kg Adult

What is the Deficit?

- patients should be adequately hydrated prior to anesthesia
- TBW = 60% or 50% of total body weight for an adult male or female, respectively (e.g. for a 70 kg adult male TBW = $70 \times 0.6 = 42$ L)
- total Na content determines ECF volume, [Na] determines ICF volume
- hypovolemia due to volume contraction
 - extra-renal Na loss
 - ♦ GI: vomiting, NG suction, drainage, fistulae, diarrhea
 - ♦ skin/resp: insensible losses (fever), sweating, burns
 - ♦ vascular: hemorrhage
 - renal Na and H₂O loss
 - ♦ diuretics
 - ♦ osmotic diuresis
 - ♦ hypoaldosteronism
 - ♦ salt-wasting nephropathies
 - renal H₂O loss
 - ♦ diabetes insipidus (central or nephrogenic)
 - hypovolemia with normal or expanded ECF volume
 - ♦ decreased cardiac output
 - ♦ redistribution
 - hypoalbuminemia: cirrhosis, nephrotic syndrome
 - capillary leakage: acute pancreatitis, rhabdomyolysis, ischemic bowel, sepsis, anaphylaxis
- replace water and electrolytes as determined by patient's needs
- with chronic hyponatremia correction must be done gradually over >48 hours to avoid CNS central pontine myelinolysis

Table 4. Signs and Symptoms of Dehydration

Percentage of Body Water Loss	Severity	Signs and Symptoms
3%	Mild	Decreased skin turgor, sunken eyes, dry mucous membranes, dry tongue, reduced sweating
6%	Moderate	Oliguria, orthostatic hypotension, tachycardia, low volume pulse, cool extremities, reduced filling of peripheral veins and CVP, hemoconcentration, apathy
9%	Severe	Profound oliguria or anuria and compromised CNS function with or without altered sensorium

What are the Ongoing Losses?

- tubes
 - Foley catheter, NG, surgical drains
- third spacing (other than ECF, ICF)
 - pleura, GI, retroperitoneal, peritoneal
 - evaporation via exposed viscera, burns
- blood loss
- ongoing loss due to surgical exposure and evaporative losses
 - minor surgery 3 cc/kg/hr e.g. laparoscopic surgery
 - intermediate surgery 6 cc/kg/hr e.g. open cholecystectomy
 - major surgery 9 cc/kg/hr e.g. abdominal aneurysm repair

IV Fluids

- replacement fluids include crystalloid and colloid solutions
- improves perfusion but NOT O₂ carrying capacity of blood

Crystalloid Infusion

- salt-containing solutions that distribute within ECF
- maintain euolemia in patient with blood loss: 3 mL crystalloid infusion per 1 mL of blood loss for volume replacement (i.e. 3:1 replacement). Controversy surrounds this as an initial vs. maximal replacement target
- after 3 L crystalloid replacement, switch to pRBCs
- if large volumes are to be given, use balanced fluids such as Ringer's lactate or Plasmalyte®, as too much normal saline (NS) may lead to hyperchloremic metabolic acidosis

Colloid Infusion (see *Blood Products*, A15)

- collected from donor blood (fresh frozen plasma, albumin, RBCs) or synthetics [e.g. hydroxyethyl starch (HES) solutions]
- distributes within intravascular volume
- 1:1 ratio (infusion: blood loss) only in terms of replacing volume
- HES colloids remain in intravascular space (metabolized by plasma serum amylase and renally excreted), two available in Canada: Voluven® and Pentaspan®

Table 5. Colloid HES Solutions

	Concentration	Plasma Volume Expansion	Duration (h)	Maximum Daily Dose (ml/kg)
Voluven®	6%	1:1	4-6	33-50
Pentaspan®	10%	1:1.2-1.5	18-24	28

Initial Distribution of IV Fluids

- H₂O follows ions/molecules to their respective compartments

Table 6. IV Fluid Solutions

		ECF	Ringer's Lactate	0.9 NS	0.45 NS	D5W	2/3 + 1/3	Plasmalyte
mEq/L	Na	142	130	154	77	-	51	140
	K	4	4	-	-	-	-	5
	Ca	4	3	-	-	-	-	-
	Mg	3	-	-	-	-	-	3
	Cl	103	109	154	77	-	51	98

Colloids versus Crystalloids for Fluid Resuscitation in Critically Ill Patients
Cochrane Library 2009; Issue 3.**Purpose:** To evaluate the effects of colloids compared to crystalloids for fluid resuscitation, specifically when used in critically ill patients.**Methods:** A meta-analysis was performed looking at randomized controlled trials comparing colloid vs. crystalloids in use with patient requiring fluid resuscitation due to traumatic injury (including burns) or post surgery. Pregnant women and neonates were excluded. Primary outcome was overall mortality.**Results:** Results are broken down based on specific colloid. For albumin (or plasma protein fraction) the relative risk (RR) was 1.00 (95% CI 0.91 - 1.10), as compared to crystalloid. For hydroxyethyl starch the RR was 1.18 (95% CI 0.96 - 1.44). Modified gelatin had a RR of 0.91 (95% CI 0.49 - 1.72) and Dextran had a RR of 1.24 (95% CI 0.94 - 1.65). For colloids mixed in a hypertonic crystalloid as compared to isotonic crystalloid the RR was 0.88 (95% CI 0.74 - 1.05).**Conclusions:** There is no evidence that use of colloids improves survival in trauma patients, burn patients or post-operative patients, when compared to crystalloid solutions. Given the increased cost of colloids as compared to crystalloids, it is recommended that crystalloids be the fluid of choice in these patients.

Blood Products

- see Hematology, H50

Table 7. Blood Products

Red Blood Cells (RBCs) (U = unit)	<ul style="list-style-type: none"> • 1 U RBCs = approx. 300 mL • 1 U RBCs increases Hb by approx. 10 g/L in a 70 kg patient • RBCs may be diluted with colloid/crystalloid to decrease viscosity • Decision to transfuse based on initial blood volume, premorbid Hb level, present volume status, expected further blood loss, patient health status • MASSIVE transfusion = $> 1 \times \text{blood volume}/24 \text{ hours}$
Autologous RBCs	<ul style="list-style-type: none"> • Replacement of blood volume with one's own RBCs • May decrease complications (infectious, febrile, etc.) • Alternative to homologous transfusion in elective procedures, but only if adequate Hb and no infection • Pre-op phlebotomy prior to elective surgery (up to 4 U collected > 1 week before surgery) • Intraoperative salvage and filtration (cell saver); contraindicated in dirty cases
Non-RBC Products	<ul style="list-style-type: none"> • Fresh frozen plasma (FFP) <ul style="list-style-type: none"> ▪ Contains all plasma clotting factors and fibrinogen close to normal plasma levels ▪ To prevent/treat bleeding due to coagulation factor depletion/deficiencies, liver impairment • Cryoprecipitate <ul style="list-style-type: none"> ▪ Contains Factors VIII and XIII, vWF, fibrinogen • Platelets <ul style="list-style-type: none"> ▪ Used in thrombocytopenia, massive transfusions, impaired platelet function • Albumin <ul style="list-style-type: none"> ▪ Selective intravascular volume expander • Erythropoietin <ul style="list-style-type: none"> ▪ Can be used pre-operatively to stimulate erythropoiesis

Calculating Acceptable Blood Losses (ABL)

- Blood volume

term infant	80 mL/kg
adult male	70 mL/kg
adult female	60 mL/kg
- Calculate estimated blood volume (EBV) (e.g. in a 70 kg male, approx. 70 mL/kg)
 $EBV = 70 \text{ kg} \times 70 \text{ mL/kg} = 4900 \text{ mL}$
- Decide on a transfusion trigger, i.e. the Hb level at which you would begin transfusion, (e.g. 70 g/L for a person with $Hb(i) = 150 \text{ g/L}$)
 $Hb(f) = 70 \text{ g/L}$
- Calculate

$$ABL = \frac{Hb(i) - Hb(f)}{Hb(i)} \times EBV$$

$$= \frac{150 - 70}{150} \times 4900 = 2613 \text{ mL}$$
- Therefore in order to keep the Hb level above 70 g/L, RBCs would have to be given after approximately 2.6 L of blood has been lost.

Transfusion Reactions

Immunosuppression

- some studies show associations between peri-operative transfusion and post-operative infection, earlier cancer recurrence, and poorer outcome

Nonimmune

- infectious risks: HIV, hepatitis B/C, Epstein-Barr virus (EBV), cytomegalovirus (CMV), brucellosis, malaria, salmonellosis, measles, syphilis
- hypervolemia
- electrolyte changes: increased K in stored blood
- dilutional coagulopathy
- dilutional thrombocytopenia
- hypothermia
- citrate toxicity
- hypocalcemia
- iron overload

A Multicenter, Randomized, Controlled Clinical Trial of Transfusion Requirements in Critical Care
NEJM 1999; 340: 409-417

Purpose: To determine whether a restrictive strategy of RBC transfusion and a liberal strategy produce equivalent results in critically ill patients.
Study: Randomized controlled trial with 60 day follow-up.

Patients: 838 critically ill patients with euvoemia after initial treatment who had Hb concentrations of less than 90 g/L within 72 hours after admission to the ICU. Mean age 57.5 years, 62.5% male.

Intervention: Patients were randomly assigned to either a restrictive strategy of transfusion, in which RBC were transfused if the Hb dropped <70 g/L and Hb concentrations were maintained between 70-90 g/L, or to a liberal strategy, in which transfusions were given when the Hb dropped <100 g/L and Hb concentrations were maintained between 100-120 g/L.

Main Outcomes: All cause mortality rates at 30 and 60 days, mortality rates during the stay in ICU and hospitalization, survival times during the first 30 days, and rates of organ failure and dysfunction.

Results: Overall, 30-day mortality was similar in the two groups. However, the rates were significantly lower with the restrictive transfusion strategy among patients who were less acutely ill (8.7% vs. 16.1%) and who were less than 55 years of age (5.7% vs. 13%), but not among patients with clinically significant cardiac disease.

The mortality rate during hospitalization was significantly lower in the restrictive-strategy group (22.2% vs. 28.1%).

Conclusions: A restrictive strategy of RBC transfusion is at least as effective as, and possibly superior to, a liberal transfusion strategy in critically ill patients, with the possible exception of patients with acute MI and unstable angina.

Table 8. Immune Transfusion Reactions

Reaction	Cause	Presentation	Management
Non-hemolytic: Febrile	<ul style="list-style-type: none"> Alloantibodies to WBC, platelet, or other donor plasma antigens 	<ul style="list-style-type: none"> Mild fever <38°C with or without rigors; may be >38°C with restlessness and shivering Nausea, facial flushing, headache, myalgias, hypotension, chest and back pain Occurs quickly; near completion of transfusion or within 2 hours 1 in 100 	<ul style="list-style-type: none"> Rule out fever due to hemolytic reaction or bacterial contamination Mild (<38°C): decrease infusion rate and give antipyretics Severe: stop transfusion, give antipyretics, antihistamines, and symptomatic treatment
Non-hemolytic: Allergic	<ul style="list-style-type: none"> Mild allergic reaction due to IgE alloantibodies to substances in donor plasma Mast cells activated with histamine release Usually occurs in pre-exposed (e.g. multiple transfusions, multiparous) 	<ul style="list-style-type: none"> Often have history of similar reactions Abrupt onset pruritic erythema/urticaria on arms and trunk, occasionally with fever Less common: involvement of face, larynx and bronchioles 1 in 100 	<ul style="list-style-type: none"> Mild: slow transfusion rate, IV antihistamines Moderate to severe: stop transfusion, IV antihistamines, subcutaneous epinephrine, hydrocortisone, IV fluids, bronchodilators Prophylactic: antihistamines 15-60 minutes prior to transfusion, washed or deglycerolized frozen RBC
Non-hemolytic: Anaphylactoid	<ul style="list-style-type: none"> In IgA deficient patients with anti-IgA antibodies receiving IgA-containing blood Immune complexes activate mast cells, basophils, eosinophils, and complement system = severe symptoms after transfusion of RBC, plasma, platelets, or other components with IgA 	<ul style="list-style-type: none"> Rare, potentially lethal Apprehension, urticarial eruptions, dyspnea, hypotension, laryngeal and airway edema, wheezing, chest pain, shock, sudden death 	<ul style="list-style-type: none"> Circulatory support with fluids, catecholamines (epinephrine), bronchodilators Respiratory assistance as indicated Evaluate for IgA deficiency and anti-IgA antibodies Future transfusions must be free of IgA: washed/deglycerolized RBCs free of IgA, blood from IgA deficient donor
Transfusion Related Acute Lung Injury (TRALI)	<ul style="list-style-type: none"> Form of noncardiogenic pulmonary edema Immunologic cause; not due to fluid overload or cardiac failure Binding of donor Ab against recipient WBC causing cytokine release leading to increased capillary permeability 	<ul style="list-style-type: none"> Occurs 2-4 hours post transfusion Respiratory distress: mild dyspnea to severe hypoxia Chest x-ray: consistent with acute pulmonary edema, but pulmonary artery and wedge pressures are not elevated 1 in 5000 	<ul style="list-style-type: none"> Usually resolves within 48 hrs with O₂, mechanical ventilation, supportive treatment
Hemolytic Acute (intravascular hemolysis)	<ul style="list-style-type: none"> Caused by donor incompatibility with recipient's blood Often due to clerical error Antibody coated RBC is destroyed by activation of complement system ABO incompatibility common cause, other RBC Ag-Ab systems can be involved 	<ul style="list-style-type: none"> Fever, chills, chest or back pain, hypotension, tachycardia, nausea, flushing, dyspnea, wheezing, hypoxemia, hemoglobinuria, diffuse bleeding due to DIC, acute renal failure <1 in 250 000 	<ul style="list-style-type: none"> Stop transfusion Notify blood bank, confirm or rule out diagnosis – clerical check, direct Coombs', repeat grouping, Rh screen and crossmatch, serum haptoglobin Manage hypotension with fluids, inotropes, other blood products Maintain urine output with crystalloids, furosemide, dopamine, alkalinize urine Component treatment if DIC, repeat grouping, Rh screen and crossmatch, serum haptoglobin Manage hypotension with fluids, inotropes, other blood products Component treatment (e.g. FFP, cryoprecipitate)
Hemolytic Delayed (extravascular hemolysis)	<ul style="list-style-type: none"> Caused by donor incompatibility with recipient's blood Generally mild, caused by antibodies to Rh system, Kell, Duffy, or Kidd antigens The level of antibody at the time of transfusion is too low to be detected or to cause hemolysis, later the level of antibody is increased due to secondary stimulus 	<ul style="list-style-type: none"> Occurs in recipients sensitized to RBC antigens by previous blood transfusion or pregnancy Anemia, mild jaundice, fever 1 to 21 days post transfusion 	<ul style="list-style-type: none"> Supportive Direct Coombs, a reexamination of pretransfusion specimens from the patient and donor for diagnosis

Extubation

- performed by trained, experienced personnel because reintubation may be required
- criteria
 - patient must no longer have intubation requirements
 - patency: airway must be patent
 - protection: patient must have intact airway reflexes
 - patient must be oxygenating and ventilating spontaneously
- laryngospasm more likely in semiconscious patient; must ensure adequate LOC
- general guidelines
 - ensure patient has normal neuromuscular function and hemodynamic status
 - ensure patient is breathing spontaneously with adequate rate and tidal volume
 - allow ventilation (spontaneous or controlled) with 100% O₂ for 3-5 minutes
 - suction secretions from pharynx
 - deflate cuff, remove ETT on inspiration (vocal cords abducted)
 - ensure patient is breathing adequately after extubation
 - ensure face mask for O₂ delivery available
 - proper positioning of patient during transfer to recovery room (e.g. lateral decubitus, head elevated)

Complications of Extubation

- early
 - aspiration
 - laryngospasm
- late
 - transient vocal cord incompetence
 - edema (glottic, subglottic)
 - pharyngitis, tracheitis

Post-Operative Care

- pain management should be continuous from OR to post-anesthetic unit (PAU) to hospital ward and home
- pain service may assist with management of post-operative inpatients

Post-Operative Nausea and Vomiting (PONV)

- hypotension and bradycardia must be ruled out
- pain and surgical manipulation also cause nausea
- often treated with dimenhydrinate (Gravol®), metoclopramide (Maxeran®) (not with bowel obstruction), prochlorperazine (Stemetil®), ondansetron (Zofran®), granisetron (Kytril®)

Post-Operative Confusion and Agitation

- ABCs first! – confusion or agitation can be caused by airway obstruction, hypercapnea, hypoxemia
- neurologic status (Glasgow Coma Scale, pupils), residual paralysis from anesthetic
- pain, distended bowel/bladder
- fear/anxiety/separation from caregivers/language barriers
- metabolic disturbance (hypoglycemia, hypercalcemia, hyponatremia – especially post-TURP)
- intracranial cause (stroke, raised intracranial pressure)
- drug effect (ketamine, anticholinergics)
- elderly patients are more susceptible to post-operative delirium

Pain Management

Definitions

- nociception: detection, transduction and transmission of noxious stimuli
- pain: perception of nociception which occurs in the brain

Acute Pain

- pain of short duration (<6 weeks) usually associated with surgery, trauma or acute illness; often associated with inflammation
- usually limited to the area of damage/trauma and resolves with healing

Risk Factors for Post-Operative Nausea and Vomiting (PONV)

- Young age
- Female
- History of PONV
- Non-smoker
- Type of surgery: ophtho, ENT, abdo/pelvic, plastics
- Type of anesthetic: N₂O, opioids, volatile agents

Drugs for Preventing Post-Operative Nausea and Vomiting.

Cochrane Library 2008; Issue 4.

Purpose: To evaluate the efficacy of antiemetics in preventing nausea and vomiting in post-operative patients.

Methods: A meta-analysis was performed looking at randomized controlled trials comparing an antiemetic to either a second antiemetic or placebo. Trials looking at dosing and/or timing of medication administration were also included. Post-operative nausea or vomiting was used as the primary outcome.

Results: 737 studies involving 103 237 patients. Eight drugs significantly reduced the occurrence of post-operative nausea and vomiting, namely: droperidol, metoclopramide, ondansetron, tropisetron, dolasetron, dexamethasone, cyclizine and granisetron. Relative risk (RR) versus placebo varied between 0.60 and 0.80. Side effects included a significant increase in drowsiness for droperidol (RR 1.32) and headache for ondansetron (1.16). The cumulative number needed to treat was 3.57.

Conclusion: Antiemetic medication is effective for reducing the occurrence of post-operative nausea and vomiting. However, further investigation needs to be done to determine whether antiemetics can cause more severe (and likely rare) side-effects, which could alter how liberally they are used.

**WHO Analgesia Ladder****Mild Pain**

Acetaminophen
NSAIDS

Moderate Pain

Codeine
Oxycodone

Severe Pain

Oxycodone
Morphine
Hydromorphone
Fentanyl

**Figure 8. Acute Pain Mechanism****Pharmacological Management of Acute Pain**

- ask the patient to rate the pain out of 10, or using visual analog scale, to determine severity

Table 9. Commonly Used Analgesics

	Acetaminophen	NSAIDs	Opioids
Examples	• Tylenol®	• Aspirin®, ibuprofen, naproxen • ketorolac (IV)	• Oral: codeine, oxycodone, morphine, hydromorphone • Parenteral: morphine, hydromorphone, fentanyl
Indications	• First-line for mild acute pain	• Mild-moderate pain	• Oral: mild and moderate acute pain • Parenteral: severe acute pain
Mechanism of Action	• ? Cyclooxygenase-2 (COX-2) inhibition • ? Modulation of endogenous cannabinoid system	• Non-selective COX-1 and -2 inhibition reducing proinflammatory prostaglandin synthesis	• Dampens nociceptive transmission between 1 st and 2 nd order neurons in the dorsal horn • Activates ascending modulatory pathways resulting in release of inhibitory neurotransmitters • Inhibits peripheral inflammatory response and hyperalgesia • Affects mood and anxiety – alleviates the affective component of perceived pain
Dosing/Administration	• Limited by analgesic ceiling beyond which there is no additional analgesia • Opioid-sparing • Max dose of 4 g/24hrs	• Limited by analgesic ceiling beyond which there is no additional analgesia • Opioid-sparing • Significant inter-individual variation in efficacy	• No analgesic ceiling (except for codeine) • Can be administered intrathecal (spinal block) or by continuous infusion • See <i>Clinical Pharmacology</i> , CP14 for opioid analgesic equivalencies
Side Effects/Toxicity	• Considered relatively safe • Liver toxicity in elevated doses	• Gastric ulceration/bleeding • Decreased renal perfusion • Photosensitivity • Premature closure of the ductus arteriosus in pregnancy	• Respiratory depression • Constipation and abdominal pain • Sedation • Nausea and vomiting • Pruritus • Confusion (particularly in the elderly)

**Use NSAIDs with Caution in Patients with:**

1. Asthma
2. Coagulopathy
3. GI ulcers
4. Renal insufficiency
5. Pregnancy, 3rd trimester

**Common Side Effects of Opioids**

1. Nausea and vomiting
2. Constipation
3. Sedation
4. Pruritis
5. Abdominal pain
6. Urinary retention
7. Respiratory depression

**PCA Parameters**

1. Loading dose
2. Bolus dose
3. Lockout interval
4. Continuous infusion (optional)
5. Max. 4 hr limit (optional)

**Advantages of PCA**

- Better pain control
- Fewer side effects
- Accommodates patient variability
- Accommodates changes in opioid requirements

- patient controlled analgesia (PCA)
 - involves the use of computerized pumps that can deliver a constant infusion as well as bolus breakthrough doses of parenterally-administered opioid analgesics
 - limited by lockout intervals
 - most commonly used agents: morphine and hydromorphone
 - refer to Table 12 for suggested infusion rate, PCA dose, and lockout intervals

Opioid Antagonists (naloxone, naltrexone)

- opioid overdose manifests primarily at CNS (e.g. respiratory depression) – manage ABCs
- opioid antagonists competitively inhibit opioid receptors, predominantly Mu (μ) receptors
- naloxone is short acting ($t_{1/2} = 1$ hr); effects of narcotic may return when naloxone wears off, therefore the patient must be observed closely following its administration
- naltrexone is longer acting ($t_{1/2} = 10$ hrs); less likely to see return of narcotic effects
- relative overdose of naloxone may cause nausea, agitation, sweating, tachycardia, hypertension, re-emergence of pain, pulmonary edema, seizures (essentially opioid withdrawal)

Regional Anesthesia

Definition of Regional Anesthesia

- local anesthetic agent (LA) applied around a peripheral nerve at any point along the length of the nerve (from spinal cord up to, but not including, the nerve endings) for the purposes of reducing or preventing impulse transmission
- no CNS depression (unless overdose of local anesthetic); patient conscious
- regional anesthetic techniques categorized as follows:
 - epidural and spinal anesthesia (neuraxial anesthesia)
 - peripheral nerve blockades
 - IV regional anesthesia (e.g. Bier block)

Preparation for Regional Anesthesia

Patient Preparation

- thorough pre-operative evaluation and assessment of patient
- technique explained to patient
- IV sedation may be indicated before block
- monitoring should be as extensive as for general anesthesia

Relative Indications for Regional Anesthesia

- avoids some of the dangers of general anesthesia, e.g. known difficult intubation, severe respiratory failure, etc.
- patient specifically requests regional anesthesia
- high quality post-operative pain relief
- general anesthesia not available/contraindicated
- titration of LA dosage for differential blockade, e.g. can block pain but preserve motor function

Complications of Regional Anesthesia

- failure of technique/inadequate anesthesia
- systemic drug toxicity due to overdose or intravascular injection
- injury to muscle, ligament or bone (back pain), to nerve root/spinal cord (nerve deficit), to epidural vein (hematoma)
- infection (e.g. osteitis, epidural abscess, meningitis)
- spinal and epidural: sympathetic blockade causing hypotension and bradycardia (occurs early, followed by sensory then motor blockade)

Epidural and Spinal Anesthesia

Anatomy of Spinal/Epidural Area (Figure 9)

- spinal cord extends to L2, dural sac to S2 in adults
- nerve roots (cauda equina) from L2 to S2
- needle inserted below L2 should not encounter cord, thus L3-L4, L4-L5 interspace commonly used
- structures penetrated
 - skin
 - subcutaneous fat
 - supraspinous ligament
 - interspinous ligament
 - ligamentum flavum (last layer before epidural space)
 - dura + arachnoid for spinal anesthesia

Patient Controlled Opioid Analgesia versus Conventional Opioid Analgesia for Postoperative Pain.

Cochrane Library 2009; Issue 1.

Purpose: To evaluate the efficacy of patient controlled analgesia (PCA) as compared to conventional 'as-needed' analgesia administration providing pain relief in post-operative patients.

Methods: Meta-analyses of randomised controlled trials comparing PCA versus conventional administration of opioid analgesia. Assessment employed a visual analog scale (VAS) for pain intensity along with overall analgesic consumption, patient satisfaction, length of stay and adverse side-effects.

Results: 55 studies with a total of 2023 patients receiving PCA and 1838 patients with standard as-needed opioid administration. PCA provided significantly better pain control through 72 hours post-operatively, but patients consumed significantly more opioids (+7 mg morphine / 24 hr, $P < 0.05$). Significantly more patients reported pruritis in the PCA group compared to control with a number needed to harm of 13. No significant difference in overall length of stay in hospital, sedation level, nausea/vomiting or urinary retention.

Conclusions: Patient controlled opioid analgesia is more effective than standard as-needed administration for reducing post-operative pain. However, patients using PCA consume more opioids overall and have more pruritis.

**Benefits of Regional Anesthesia**

- Reduced peri-op pulmonary complications
- Reduced peri-op analgesia requirements
- Decreased PONV
- Reduced peri-op blood loss
- Ability to monitor CNS status during procedure
- Improved perfusion
- Lower incidence of VTE

Figure 9. Landmarks for Placement of Epidural/Spinal

Landmarking Epidural/Spinal Anesthesia

Spinous processes should be maximally flexed

L4 spinous processes found between iliac crests

Common sites of insertion are L3-L4 and L4-L5

Classic Presentation of Dural Puncture Headache

1. Onset 6 hrs – 3 days after dural puncture
2. Postural component (worse sitting)
3. Occipital or frontal localization
4. \pm tinnitus, diplopia

Reduction of Postoperative Mortality and Morbidity with Epidural or Spinal Anaesthesia: Results from Overview of Randomised Trials

BMJ 2000; 321:1-12
Purpose: To obtain reliable estimates of the effects of neuraxial blockade with epidural or spinal anesthesia on postoperative morbidity and mortality.

Study: Systematic review of all trials with randomization to intra-operative neuraxial blockade versus not.

Patients: 141 trials including 9559 patients.

Main Outcomes: All cause mortality, MI, PE, DVT, transfusion requirements, pneumonia, other infections, respiratory depression, and renal failure.

Results: Overall mortality was reduced by about a third in patients allocated to neuraxial blockade. Neuraxial blockade reduced the risk of PE by 55%, DVT by 44%, transfusion requirements by 50%, pneumonia by 39%, and respiratory depression by 59%. There were also reductions in MI and renal failure. The proportional reductions in mortality did not clearly differ by surgical group, type of blockade (epidural or spinal), or in those trials in which neuraxial blockade was combined with general anesthesia compared with trials in which neuraxial blockade was used alone.

Conclusions: Neuraxial blockade reduces postoperative mortality and other serious complications.

Table 10. Epidural versus Spinal Anesthesia

	Epidural	Spinal
Deposition Site	LA deposited in epidural space (space between ligamentum flavum and dura) Initial blockade is at the spinal roots followed by some degree of spinal cord anesthesia as LA diffuses into the subarachnoid space through the dura	LA injected into subarachnoid space in the dural sac surrounding the spinal cord and nerve roots
Onset	Significant blockade requires 10-15 minutes Slower onset of side effects	Rapid blockade (onset in 2-5 minutes)
Effectiveness	Effectiveness of blockade can be variable	Very effective blockade
Difficulty	Technically more difficult; greater failure rate	Easier to perform due to visual confirmation of CSF flow
Patient Positioning	Position of patient not as important; specific gravity not an issue	Hyperbaric LA solution – position of patient important
Specific Gravity/Spread	Solutions injected here spread throughout the potential space; specific gravity of solution does not affect spread	LA solution may be made hyperbaric (of greater specific gravity than the cerebrospinal fluid by mixing with 10% dextrose, thus increasing spread of LA to the dependent (low) areas of the subarachnoid space)
Dosage	Larger volume/dose of LA (usually > toxic IV dose)	Smaller dose of LA required (usually < toxic IV dose)
Continuous Infusion	Use of catheter allows for continuous infusion or repeat injections	None
Complications	Failure of technique Hypotension Bradycardia if cardiac sympathetics blocked (only if ~T2-4 block) Epidural or subarachnoid hematoma Accidental subarachnoid injection can produce spinal anesthesia (and any of the above complications) Systemic toxicity of LA (accidental intravenous) Catheter complications (shearing, kinking, vascular or subarachnoid placement) Infection Dural puncture	Failure of technique Hypotension Bradycardia if cardiac sympathetics blocked (only if ~T2-4 block), i.e. "high spinal" Epidural or subarachnoid hematoma Post-spinal headache (CSF leak) Persistent paresthesias (usually transient) Spinal cord trauma, infection
Combined Spinal-Epidural	Combines the benefits of rapid, reliable, intense blockade of spinal anesthesia together with the flexibility of an epidural catheter	

LA = Local anesthetic agent

Contraindications to Spinal/Epidural Anesthesia

- absolute contraindications
 - lack of proper equipment or properly trained personnel
 - lack of IV access
 - allergy to LA
 - infection at puncture site or underlying tissues
 - coagulopathies
 - raised ICP
 - sepsis/bacteremia
 - hemodynamic instability/uncorrected hypovolemia
- relative contraindications
 - bacteremia
 - pre-existing neurological disease
 - aortic/mitral valve stenosis (i.e. fixed cardiac output states)
 - previous spinal surgery, severe kyphoscoliosis
 - severe/unstable psychiatric disease or emotional instability

Peripheral Nerve Blocks

- generally used for post-operative analgesia; sometimes uses for intra-operative anesthesia
- relatively safe
- 2 cardinal rules: 1. Avoid intraneural injection 2. Avoid neurotoxic agents
- e.g. brachial plexus block, femoral nerve block, digital ring block, etc.
- can be ultrasound-guided to prevent neural injury

Contraindications to Peripheral Nerve Blockade

- allergy to local anesthetic (LA)
- patient refusal, lack of cooperation
- lack of resuscitation equipment
- lack of IV access
- certain types of pre-existing neurological dysfunction (e.g. ALS, MS)
- local infection at block site

Local Anesthesia

Local Anesthetic Agents (LA)

- see Table 17 for list of local anesthetic agents

Definition and Mode of Action

- LA are drugs that block the generation and propagation of impulses in excitable tissues: nerves, skeletal muscle, cardiac muscle, brain
- LA bind to receptor (on the cytosolic side of the Na channel, i.e. lipid soluble), inhibiting Na flux and thus blocking impulse conduction
- different types of nerve fibres undergo blockade at different rates

Absorption, Distribution, Metabolism

- LA readily crosses the blood-brain barrier (BBB) once absorbed into the bloodstream
- **ester-type** LA (procaine, tetracaine) are broken down by plasma and hepatic esterases; metabolites excreted via kidneys
- **amide-type** LA (lidocaine, bupivacaine) are broken down by hepatic mixed-function oxidases (P450 system); metabolites excreted via kidneys

Selection of LA

- choice of LA depends on
 - onset of action: influenced by pKa (the lower the pKa, the higher the concentration of the base form of the LA and the faster the onset of action)
 - duration of desired effects: influenced by protein binding (longer duration of action when protein binding of LA is strong)
 - potency: influenced by lipid solubility (agents with high lipid solubility penetrate the nerve membrane more easily)
 - unique needs (e.g. sensory blockade with relative preservation of motor function by bupivacaine at low doses)
 - potential for toxicity

Systemic Toxicity

- see Table 17 for max doses, potency and duration of action for common LA agents
- occurs by accidental intravascular injection, LA overdose, or unexpectedly rapid absorption
- CNS effects first appear to be excitatory due to initial block of inhibitory fibres; then subsequent block of excitatory fibres
- CNS effects (in order of appearance) (Figure 10)
 - numbness of tongue, perioral tingling, metallic taste
 - disorientation, drowsiness
 - tinnitus
 - visual disturbances
 - muscle twitching, tremors
 - unconsciousness
 - convulsions, seizures
 - generalized CNS depression, coma, respiratory arrest
- CVS effects
 - vasodilation, hypotension
 - decreased myocardial contractility

Figure 10. Local Anesthetic Systemic Toxicity

- dose-dependent delay in cardiac impulse transmission
 - ♦ prolonged PR, QRS intervals
 - ♦ sinus bradycardia
- CVS collapse
- treatment of systemic toxicity
 - early recognition of signs
 - 100% O₂, manage ABCs
 - diazepam or sodium thiopental may be used to increase seizure threshold
 - if the seizures are not controlled by diazepam or thiopental, consider using succinylcholine (stops muscular manifestations of seizures, facilitates intubation)
 - manage arrhythmias
 - consider Intralipid® 20% to bind local anesthesia in circulation

Local Infiltration, Hematoma Blocks

Local Infiltration

- injection of tissue with local anesthetic agent (LA), producing a lack of sensation in the infiltrated area due to LA acting on nerve endings
- suitable for small incisions, suturing, excising small lesions
- can use fairly large volumes of dilute LA to infiltrate a large area
- low concentrations of epinephrine (1:100,000-1:200,000) cause vasoconstriction, thus reducing bleeding and prolonging the effects of LA by reducing systemic absorption

Fracture Hematoma Block

- special type of local infiltration for pain control during manipulation of certain fractures
- hematoma created by fracture is infiltrated with LA to anesthetize surrounding tissues
- sensory blockade may be only partial
- no muscle relaxation

Topical Anesthetics

- various preparations of local anesthetics available for topical use, may be a mixture of agents, e.g. EMLA cream is a combination of 2.5% lidocaine and prilocaine
- must be able to penetrate the skin or mucous membrane

Obstetrical Anesthesia

Physiologic Changes in Pregnancy

1. **airway**
 - upper airway becomes edematous and friable
 - decreased FRC and increased O₂ consumption → desaturation
2. **cardiovascular system**
 - increased blood volume > increased RBC mass → mild anemia
 - decreased SVR proportionately greater than increased CO → decreased BP
 - prone to decreased BP due to aortocaval compression
3. **central nervous system**
 - decreased MAC due to hormonal effects
 - increased block height due to engorged epidural veins
4. **gastrointestinal system**
 - delayed gastric emptying
 - increased volume and acidity of gastric fluid
 - decreased LES tone
 - increased abdominal pressure
 - combined, these lead to an increased risk of aspiration

Options for Analgesia during Labour

1. **psychoprophylaxis** – Lamaze method
 - patterns of breathing and focused attention on fixed object
2. **systemic medication**
 - easy to administer, but risk of maternal or neonatal depression
 - common drugs: opioids (morphine, meperidine)
3. **inhalational analgesia**
 - easy to administer, makes uterine contractions more tolerable, but does not relieve pain completely
 - 50% nitrous oxide

Where Not to Use Local Anesthetic Agent (LA) with Epinephrine
 "Fingers, Toes, Penis, Nose"

The Effect of Epidural Analgesia on Labour, Maternal, and Neonatal Outcomes: A Systematic Review

Am J Obstet Gynecol 2002; 186:S69-77

Study: Meta-analysis of 14 studies with 4324 women.

Selection Criteria: Randomized controlled trials and prospective cohort studies between 1980-2001 comparing epidural analgesia to parenteral opioid administration during labour.

Types of Participants: Healthy women with uneventful pregnancies.

Intervention: Participants were randomized to either epidural analgesia or parenteral opioid administration during labour.

Outcomes and Results: Maternal – there were no differences between the 2 groups in first-stage labour length, incidence of Caesarean delivery, incidence of instrumented vaginal delivery for dystocia, nausea, or mid-to-low back pain post-partum. However, second-stage labour length was longer (mean = 15 min) and there were greater reports of fever and hypotension in the epidural group. Also, lower pain scores and greater satisfaction with analgesia were reported among the epidural group. There was no difference in lactation success at 6 weeks and urinary incontinence was more frequent in the epidural group immediately post-partum, but not at 3 months or 1 year (evidence from PC studies only). Neonatal – there were no differences between the 2 groups for incidence of fetal heart rate abnormalities, intrapartum meconium, poor 5-min Apgar score, or low umbilical artery pH. However, the incidence of poor 1-min Apgar scores and need for neonatal naloxone were higher in the parenteral opioid group.

Conclusions: Epidural analgesia is a safe intrapartum method for labour pain relief and women should not avoid epidural analgesia for fear of neonatal harm, Caesarean delivery, breastfeeding difficulties, long-term back pain or long-term urinary incontinence.

4. regional anesthesia

- provides excellent analgesia with minimal depressant effects
- hypotension is the most common complication
- maternal BP monitored q2-5 min for 15-20 min after initiation and regularly thereafter
- epidural usually given as it preferentially blocks sensation, leaving motor function intact

Options for Caesarean Section

- regional:** spinal or epidural
- general:** used if contraindications or time precludes regional blockade

Potential complications of anesthesia in Caesarean section:

- aspiration under general anesthesia: due to increased gastroesophageal reflux
- hypotension and/or fetal distress: caused by aortocaval compression; corrected by turning patient into the left lateral decubitus (LLD) position or using left uterine displacement (LUD)
- unintentional total spinal anesthesia
- LA-induced seizures: due to intravascular injection of LA
- post-dural puncture headache
- nerve injury (rare)

Nociceptive Pathways in Labour and Delivery

Labour

- Cervical dilation and effacement
- Visceral nerve fibres entering the spinal cord at T10-L1

Delivery

- Distention of lower vagina and perineum
- Somatic nociceptive impulses via the pudendal nerve entering the spinal cord at S2-S4

Pediatric Anesthesia

Respiratory System

- in comparison to adults, anatomical differences in infants include (Figure 11)
 - large head, short trachea/neck, large tongue, adenoids and tonsils
 - narrow nasal passages (obligate nasal breathers until 5 months)
 - narrowest part of airway at the level of the cricoid vs. glottis in adults
 - epiglottis is longer, U shaped and angled at 45 degrees; carina is wider and is at the level of T2 (T4 in adults)
- physiologic differences include
 - faster RR, immature respiratory centres which are depressed by hypoxia/hypercapnea (airway closure occurs in the neonate at the end of expiration)
 - less oxygen reserve during apnea – decreased total lung volume, vital and functional reserve capacity together with higher metabolic needs
 - greater V/Q mismatch – lower lung compliance due to immature alveoli (mature at 8 years)
 - greater work of breathing – greater chest wall compliance, weaker intercostals/diaphragm and higher resistance to airflow
- a pediatric breathing unit is required for all children <20 kg

Cardiovascular System

- blood volume at birth is approximately 80 mL/kg; transfusion should be started if >10% of blood volume lost
- children have a high pulse rate and low BP
- CO is increased by increasing HR, not stroke volume because of low heart wall compliance; therefore, bradycardia → severe compromise in CO

Temperature Regulation

- vulnerable to hypothermia
- minimize heat loss by use of warming blankets, covering the infant's head, humidification of inspired gases and warming of infused solutions

Central Nervous System

- the MAC of halothane is increased compared to the adult (i.e. 0.75% adult, 0.87% neonates, 1.2% infant)
- the neuromuscular junction is immature for the first 4 weeks of life and thus there is an increased sensitivity to non-depolarizing relaxants
- parasympathetics mature at birth, sympathetics mature at 4-6 months → autonomic imbalance
- infant brain is 12% of body weight and receives 34% of CO (adult: 2% body weight and 14% CO)

Glucose Maintenance

- infants less than 1 year can become seriously hypoglycemic during pre-operative fasting and post-operatively if feeding is not recommenced as soon as possible
- after 1 year children are able to maintain normal glucose homeostasis in excess of 8 hours

© Leanne Chan 2011

- Larger tongue in proportion to mouth
- Smaller pharynx
- Larger and more flaccid epiglottis
- Larynx is more superior and anterior
- Narrowest point at cricoid cartilage
- Trachea is more narrow and less rigid

Figure 11. Comparison of Pediatric vs. Adult Airway

To increase alveolar minute ventilation in neonates, increase respiratory rate, not tidal volume.

Neonate 30-40 bpm

1-13 yrs $(24 - \frac{\text{age}}{2})$
min

ETT Sizing in Pediatrics

Diameter of tracheal tube in children (mm) after 1 year = $\frac{\text{age}}{4} + 4$

Length of tracheal tube (cm) = $\frac{\text{age}}{2} + 12$

Pharmacology

- higher dose requirements because of higher TBW (75% vs. 60% in adults) and greater volume of distribution
- barbiturates/opioids more potent due to greater permeability of BBB
- muscle relaxants
 - non-depolarizing
 - ♦ immature NMJ, variable response
 - depolarizing
 - ♦ must pretreat with atropine or may experience profound bradycardia, sinus node arrest due to PNS > SNS (also dries oral secretions)
 - ♦ more susceptible to arrhythmias, hyperkalemia, rhabdomyolysis, myoglobinemia, masseter spasm, and malignant hyperthermia

Uncommon Complications

Malignant Hyperthermia (MH)

- hypermetabolic disorder of skeletal muscle
- due to an uncontrolled increase in intracellular Ca (because of an anomaly of the ryanodine receptor which regulates the Ca channel in the sarcoplasmic reticulum of skeletal muscle)
- autosomal dominant (AD) inheritance
- incidence of 1-5:100,000, may be associated with skeletal muscle abnormalities such as dystrophy or myopathy
- anesthetic drugs triggering MH crises
 - volatile anesthetics: any drug ending in “-ane”
 - depolarizing relaxants: succinylcholine (SCh), decamethonium

Clinical Picture

- onset: immediate or hours after contact with trigger agent
 - increased oxygen consumption
 - increased end-tidal CO₂ on capnograph
 - tachycardia/dysrhythmia
 - tachypnea/cyanosis
 - increased temperature (late sign)
 - hypertension
 - diaphoresis
- muscular symptoms
 - trismus (masseter spasm) common but not specific for MH (occurs in 1% of children given SCh with halothane anesthesia)
 - tender, swollen muscles due to rhabdomyolysis
 - trunk or total body rigidity

Complications

- death
- coma
- disseminated intravascular coagulation (DIC)
- muscle necrosis/weakness
- myoglobinuric renal failure/hepatic dysfunction
- electrolyte abnormalities (e.g. hyperkalemia) and secondary arrhythmias
- ARDS
- pulmonary edema

Prevention

- suspect MH in patients with a family history of problems/death with anesthetic
- dantrolene prophylaxis no longer routine
- avoid all trigger medications (use regional if possible) and use “clean” equipment
- central body temp and end-tidal CO₂ monitoring

Malignant Hyperthermia Management [Based on Malignant Hyperthermia Association of the U.S. (MHAUS) Guidelines, 2008]

1. notify surgeon, discontinue volatile agents and succinylcholine, hyperventilate with 100% oxygen at flows of 10 L/min or more; halt the procedure as soon as possible
2. dantrolene 2.5 mg/kg rapidly IV, through large-bore IV if possible
 - repeat until there is control of signs of MH; sometimes up to 30 mg/kg is necessary
3. bicarbonate 1-2 mEq/kg if blood gas values are not available for metabolic acidosis

**Signs of Malignant Hyperthermia**

- Unexplained rise in end-tidal CO₂
- Increase in minute ventilation
- Tachycardia
- Hyperthermia (late sign)
- Rigidity

**Basic Principles of MH Management**

- CALL FOR HELP
- Turn off potential triggering agents
- Notify operating personnel
- Administer dantrolene 2.5 mg/kg q5minutes
- Cool patient to 38°C
- Monitor and correct blood gases, electrolytes, and glucose

4. cool the patients with core temp $>39^{\circ}\text{C}$
 - lavage open body cavities, stomach, bladder, rectum, apply ice to surface, infuse cold saline IV
 - stop cooling if temp is $<38^{\circ}\text{C}$ and falling to prevent drift to $<36^{\circ}\text{C}$
5. dysrhythmias usually respond to treatment of acidosis and hyperkalemia
 - use standard drug therapy except Ca channel blockers as they may cause hyperkalemia and cardiac arrest in presence of dantrolene
6. hyperkalemia
 - treat with hyperventilation, bicarbonate, glucose/insulin, calcium
 - bicarb 1-2 mEq/kg IV, calcium chloride 10 mg/kg or calcium gluconate 10-50 mg/kg for life-threatening hyperkalemia and check glucose levels hourly
7. follow ETCO_2 , electrolytes, blood gases, CK, core temperature, urine output and colour with Foley catheter, coagulation studies
 - if CK and/or potassium rises more than transiently or urine output falls to less than 0.5 ml/kg/hr, induce diuresis to >1 ml/kg/hr urine to avoid myoglobinuric renal failure
8. maintain anesthesia with benzodiazepines, opioid, and propofol
9. transfer to ICU bed

Common Medications

Table 11. Intravenous Induction Agents

	Propofol (Diprivan®)	Thiopental (Pentothal®, sodium thiopental, sodium thiopentone)	Ketamine (Ketalar®, Ketaject®)	Benzodiazepines [midazolam (Versed®), diazepam (Valium®), lorazepam (Ativan®)]
Class	• Alkylphenol – hypnotic	• Ultra-short acting thiobarbiturate – hypnotic	• Phencyclidine (PCP) derivative – dissociative	• Benzodiazepines
Action	• Inhibitory at GABA synapse • Decreased cerebral metabolic rate + blood flow, decreased ICP, decreased SVR, decreased BP, and decreased SV	• Decreased time Cl channels open facilitating GABA and suppressing glutamic acid • Decreased cerebral metabolism + decreased blood flow, decreased CPP, decreased CO, decreased BP, decreased reflex tachycardia, decreased respiration	• May act on NMDA, opiate and other receptors • Increased HR, increased BP, increased SVR, increased coronary flow, increased myocardial O_2 uptake, CNS + respiratory depression, bronchial smooth muscle relaxation	• Causes increased glycine inhibitory neurotransmitter, facilitates GABA • Produces antianxiety and skeletal muscle relaxant effects • Minimal cardiac depression
Indications	• Induction • Maintenance • Total intravenous anesthesia (TIVA)	• Induction • Control of convulsive states	• Major trauma, hypovolemia, severe asthma because sympathomimetic	• Used for sedation, amnesia and anxiolysis
Caution	• Allergy (egg, soy) • Pts who cannot tolerate sudden decreased BP (i.e. fixed cardiac output or shock)	• Allergy to barbiturates • Uncontrolled hypotension, shock, cardiac failure • Porphyria, liver disease, status asthmaticus, myxedema	• Ketamine allergy • TCA medication (interaction causes HTN and dysrhythmias) • History of psychosis • Pt cannot tolerate HTN (e.g. CHF, increased ICP, aneurysm)	• Marked respiratory depression
Dosing	• IV induction: 2.5-3.0 mg/kg (less with opioids or premeds) TIVA • Unconscious <1 min • Lasts 4-6 min • $t_{1/2}=0.9$ hrs • Decreased post-op sedation, recovery time, N/V	• IV induction: 3-5 mg/kg TIVA • Unconscious about 30s • Lasts 5 min • Accumulation with repeat dosing – not for maintenance • $t_{1/2}=5-12$ hrs • Post-op sedation lasts hours	• IV induction 1-2 mg/kg • Dissociation in 15s, analgesia, amnesia and unconsciousness in 45-60s • Unconscious for 10-15 min, analgesia for 40 min, amnesia for 1-2 hrs • $t_{1/2} = \sim 3$ hrs	• Onset less than 5 minutes if given IV • Duration of action long but variable/somewhat unpredictable
Special Considerations	• 0-30% decreased BP due to vasodilation • Reduce burning at IV site by mixing with lidocaine	• Combining with rocuronium causes precipitates to form	• High incidence of emergence reactions (vivid dreaming, out-of-body sensation, illusions) • Pretreat with glycopyrrolate to decrease salivation	• Antagonist: flumazenil (Anexate®) competitive inhibitor, 0.2 mg IV over 15s, repeat with 0.1 mg/min (max of 2 mg), $t_{1/2}$ of 60 minutes • Midazolam also has amnestic (antegrade) effect + decreased risk of thrombophlebitis

Table 12. Opioids

Agent	Infusion Rate	PCA Dose	PCA Lockout Interval	
Morphine	0.3-0.9 mg/h	0.2-0.3 mg	30 minutes	
Fentanyl	25-50 µg/h	20-30 µg	15 minutes	
Hydromorphone	0.1-0.2 mg/h	0.15 µg	30 minutes	

Agent	Moderate Dose (IV)	Onset	Duration	Special Considerations
Morphine	0.2-0.3 mg/kg	Moderate (5-10 min)	Moderate (4-5 h)	Histamine release leading to decrease in BP
Meperidine (Demerol®)	2-3 mg/kg	Moderate (10 min)	Moderate (2-4 h)	Anticholinergic, hallucinations, less pupillary constriction than morphine, metabolite build up may cause seizures
Codeine	0.5-1 mg/kg (no IV)	Late (30-60 min)	Moderate (4-6 h)	Primarily post-operative use, not for IV use
Hydromorphone (Dilaudid®)	30-80 µg/kg	Moderate (15 min)	Moderate (4-5 h)	
Fentanyl	3-10 µg/kg	Rapid (<5 min)	Short (0.5-1 h)	Transient muscle rigidity in very high doses
Remifentanyl	0.5-1.5 µg/kg	Rapid (1-3 min)	Ultra short (<10 min)	Only use during induction and maintenance of anesthesia

In general, parenteral route is 2-3 times more potent than oral.

Table 13. Volatile Inhalational Agents

	Sevoflurane	Desflurane	Isoflurane	Enflurane	Halothane	Nitrous oxide (N ₂ O)*
MAC	2.0	6.0	1.2	1.7	0.8	104 (% gas in O ₂)
CNS	Increased ICP	Increased ICP	Decreased cerebral metabolic rate Increased ICP	ECG seizure-like activity, increased ICP	Increased ICP and CBF	—
Resp	Respiratory depression (severely decreased TV, increased RR), decreased response to respiratory CO ₂ reflexes, bronchodilation					—
CVS	Less decrease of contractility, stable HR	Tachycardia with rapid increase in concentration	Decreased BP and CO, increased HR, theoretical chance of coronary steal**	Stable HR, decreased contractility	Decreased BP, CO, HR and conduction Sensitizes myocardium to epinephrine-induced arrhythmias	Can cause decreased HR in pediatric cases in those with existing heart disease
MSK	Muscle relaxation, potentiation of other muscle relaxants, uterine relaxation					

*Properties and Adverse Effects of N₂O

Due to its high MAC, nitrous oxide is combined with other anesthetic gases to attain surgical anesthesia. A MAC of 104% is possible in a pressurized chamber only.

Second Gas Effect: see Determinants of Speed of Onset of Volatile Anesthetics sidebar, A6.

Expansion of closed spaces: closed spaces such as a pneumothorax, the middle ear, bowel lumen and ETT cuff will markedly enlarge if N₂O is administered.

Diffusion hypoxia: During anesthesia, the washout of N₂O from body stores into alveoli can dilute the alveolar [O₂], creating a hypoxic mixture if the original [O₂] is low.

**Coronary Steal: N₂O causes small vessel dilation which may compromise blood flow to poorly perfused areas of heart.

Table 14. Depolarizing Muscle Relaxants (Non-Competitive): Succinylcholine (SCh)

Mechanism of Action	Mimics ACh and binds to ACh receptors causing prolonged depolarization; initial fasciculation may be seen, followed by temporary paralysis secondary to blocked ACh receptors by SCh
Intubating Dose	1-2 mg/kg
Onset	30-60 seconds – RAPID (fastest of all muscle relaxants)
Duration	5-10 minutes – SHORT (no reversing agent for SCh)
Metabolism	SCh is hydrolyzed by plasma cholinesterase (pseudocholinesterase), found only in plasma and not at the NMJ
Indications	<ul style="list-style-type: none"> • Assist intubation • Increased risk of aspiration (need rapid paralysis and airway control) • Short procedures (e.g. full stomach), DM, hiatus hernia, obesity, pregnancy, trauma • Electroconvulsive therapy (ECT) • Laryngospasm
Side Effects	<ol style="list-style-type: none"> 1. SCh also stimulates muscarinic cholinergic autonomic receptors (in addition to nicotinic receptors) <ul style="list-style-type: none"> • May cause bradycardia, dysrhythmias, sinus arrest, increased secretions of salivary glands (especially in children) 2. Hyperkalemia <ul style="list-style-type: none"> • Disruption of motor nerve activity causes proliferation of extrajunctional (outside NMJ) cholinergic receptors • Depolarization of an increased number of receptors by SCh may lead to massive release of potassium out of muscle cells • Patients at risk: <ul style="list-style-type: none"> • 3rd degree burns 24 hrs-6 mths after injury • Traumatic paralysis or neuromuscular diseases (e.g. muscular dystrophy) • Severe intra-abdominal infections • Severe closed head injury • Upper motor neuron lesions 3. Can trigger malignant hyperthermia (MH) 4. Increase ICP/intraocular pressure (IOP)/intra gastric pressure (no increased risk of aspiration if competent lower esophageal sphincter) 5. Fasciculations, post-op myalgia – may be minimized if small dose of non-depolarizing agent given before SCh administration
Contraindications	
Absolute	Known hypersensitivity or allergy, positive history of malignant hyperthermia, myotonia (m. congenita, m. dystrophica, paramyotonia congenita), high risk for hyperkalemic response
Relative	Known history of plasma cholinesterase deficiency, myasthenia gravis, myasthenic syndrome, familial periodic paralysis, open eye injury

Table 15. Non-Depolarizing Muscle Relaxants (Competitive)

Mechanism of Action	Competitive blockade of postsynaptic ACh receptors preventing depolarization					
Classification	Short	Intermediate			Long	
	Mivacurium	Rocuronium	Vecuronium	Cisatracurium	Pancuronium	Doxacurium
Intubating Dose (mg/kg)	0.2	0.6	0.1	0.1	0.1	0.05
Onset (min)	2-3	1.5	2-3	3	3-5	5-7
Duration (min)	15-25	30-45	45-60	40-60	90-120	90-120
Metabolism	Plasma cholinesterase	Liver (major) Renal (minor)	Liver	Hofmann Eliminations	Renal (major) Liver (minor)	Renal
Indications	Assist intubation, assist mechanical ventilation in some ICU patients, reduce fasciculations and post-op myalgias secondary to SCh					
Side Effects						
Histamine Release	Yes	No	No	No	No	Yes
Other	—	—	—	—	Tachycardia	—
Considerations	Increased duration of action in renal or liver failure	Quick onset of rocuronium allows its use in rapid sequence induction Cisatracurium is good for patients with renal or hepatic insufficiency			Pancuronium if increased HR and BP desired, doxacurium if cardiovascular stability needed	

Table 16. Reversal Agents for Non-Depolarizing Relaxants

Cholinesterase Inhibitor	Neostigmine	Pyridostigmine	Edrophonium
Onset and Duration	Intermediate	Longest	Shortest
Mechanism of Action	Inhibits enzymatic degradation of ACh, increases ACh at nicotinic and muscarinic receptors, displaces non-depolarizing muscle relaxants Muscarinic effects of reversing agents include unwanted bradycardia, salivation and increased bowel peristalsis*		
Dose	0.04-0.08 mg/kg	0.1-0.4 mg/kg	0.5-1 mg/kg
Recommended Anticholinergic	Glycopyrrolate	Glycopyrrolate	Atropine
Dose of Anticholinergic per mg	0.2 mg	0.05 mg	0.014 mg

*Atropine and glycopyrrolate are anticholinergic agents administered during the administration of reversal agents to minimize muscarinic effects

Table 17. Local Anesthetic Agents

	Max. Dose	Max. Dose with Epinephrine	Potency	Duration
chlorprocaine	11 mg/kg	14 mg/kg	Low	15-30 min
lidocaine	5 mg/kg	7 mg/kg	Medium	1-2 hours
bupivacaine	2.5 mg/kg	3 mg/kg	High	3-8 hours

Basic Anatomy Review

Coronary Circulation

- conventional arterial supply to the heart arises from the right and left coronary arteries, originating from the root of the aorta (see Figure 1)
 - right coronary artery (RCA)
 - ♦ acute marginal branches
 - ♦ atrioventricular (AV) nodal artery
 - ♦ posterior interventricular artery (PIV) = posterior descending artery (PD)
 - left main coronary artery (LCA): two major branches
 - ♦ left anterior descending artery (LAD)
 - septal branches
 - diagonal branches
 - ♦ left circumflex artery (LCx)
 - obtuse marginal branches
- dominance of circulation
 - right-dominant circulation: PIV and at least one posterolateral branch arise from RCA (80%)
 - left-dominant circulation: PIV and at least one posterolateral branch arise from LCx (15%)
 - balanced circulation: dual supply of posteroinferior LV from RCA and LCx (5%)
- the sinoatrial (SA) node is supplied by the SA nodal artery, which may arise from the RCA (60%) or LCA (40%)
- most venous blood from the heart drains into the RA through the coronary sinus, although a small amount drains through Thebesian veins into all four chambers, contributing to the physiologic R-L shunt

Figure 1. Anatomy of the Coronary Arteries (right anterior oblique projection)

Figure 2a. Cardiac Cycle

Figure 2b. Cardiac Cycle, JVP Pulse and Carotid Pulse

Cardiac Anatomy

- **layers of the heart**
 - endocardium
 - myocardium
 - epicardium = visceral pericardium
 - pericardial space
 - parietal pericardium
- **valves**
 - tricuspid valve (TV): separates RA and RV
 - pulmonic valve (PV): separates RV and pulmonary artery (PA)
 - mitral valve (MV): separates LA and LV
 - aortic valve (AV): separates LV and ascending aorta
- **conduction system**
 - impulses travel from: SA node → AV node → bundle of His → LBB/RBB → Purkinje fibres
 - SA node governs pacemaking control
 - anterior-, middle- and posterior-internal nodal tracts carry impulses in the right atrium and along Bachmann's bundle in the left atrium
 - atrial impulses converge at the AV node
 - ♦ the AV node is the only conducting tract from the atria to the ventricles because of electrical isolation by the annulus fibrosis (except when accessory pathways are present)
 - the bundle of His bifurcates into left and right bundle branches (LBB and RBB)
 - LBB further splits into anterior and posterior fascicles
 - RBB and fascicles of LBB give off Purkinje fibres which conduct impulses into the ventricular myocardium
- **cardiovascular innervation**
 - **sympathetic nerves**
 - ♦ innervate the sinoatrial node (SAN), atroventricular node (AVN), ventricular myocardium and vasculature
 - ♦ SAN (β_1) fibres increase pacemaking activity (chronotropy)
 - ♦ cardiac muscle (β_1) fibres increase contractility (inotropy) to help increase cardiac output
 - ♦ stimulation of β_1 - and β_2 -receptors in the skeletal and coronary circulation causes vasodilatation
 - **parasympathetic nerves**
 - ♦ innervate the SAN, AVN, atrial myocardium but few vascular beds
 - ♦ basal vagal tone dominates the tonic sympathetic stimulation of the SAN and AVN resulting in slowing of pacemaking activity and conduction (i.e. reduced chronotropy and dromotropy)
 - ♦ parasympathetics have very little impact on total peripheral vascular resistance

Figure 3. Conduction System of the Heart

Differential Diagnoses of Common Presentations

Note: **bold** text indicates most common, underlined text indicates life threatening

Chest Pain

- Pulmonary
 - **pneumonia**
 - pulmonary embolism (PE)
 - pneumothorax/hemothorax, tension pneumothorax
 - empyema
 - pulmonary neoplasm
 - bronchiectasis
 - TB
- Cardiac
 - MI/angina
 - myocarditis
 - pericarditis/Dressler's syndrome
 - cardiac tamponade
- Gastrointestinal
 - esophageal: spasm, **GERD**, esophagitis, ulceration, achalasia, neoplasm, Mallory-Weiss syndrome
 - PUD
 - gastritis
 - pancreatitis
 - biliary colic
- Mediastinal
 - lymphoma
 - thymoma
- Vascular
 - dissecting aortic aneurysm
- Surface structures
 - costochondritis
 - rib fracture
 - skin (bruising, shingles)
 - breast

Syncope

- Hypovolemia
- Cardiac
 - structural or obstructive causes
 - ♦ myocardial disease (e.g. acute coronary syndrome)
 - ♦ aortic stenosis
 - ♦ hypertrophic cardiomyopathy (HCM)
 - ♦ cardiac tamponade/constrictive pericarditis
 - arrhythmias (see arrhythmia section)
- Respiratory
 - massive PE
 - pulmonary hypertension
 - hypoxia
 - hypercapnia
- Neurologic
 - stroke/TIA (esp. vertebrobasilar insufficiency)
 - migraine
 - seizure
 - **vasovagal**
- Metabolic
 - **anemia**
 - **hypoglycemia**
- Drugs
 - antihypertensives
 - antiarrhythmics
 - beta-blockers, CCBs
- Psychiatric
 - panic attack

Local Edema

- Inflammation/infection
- Venous or lymphatic obstruction
 - thrombophlebitis/deep vein thrombosis
 - chronic lymphangitis
 - venous insufficiency
 - filariasis

Generalized Edema

- Increased hydrostatic pressure
 - increased fluid retention
 - ♦ cardiac causes e.g. CHF
 - ♦ hepatic causes e.g. cirrhosis
 - ♦ renal causes e.g. acute and chronic renal failure
 - vasodilators (especially CCBs)
 - refeeding edema
- Decreased oncotic pressure
 - hypoalbuminemia
- Hormonal
 - hypothyroidism
 - exogenous steroids
 - pregnancy
 - estrogens

Palpitations

- Cardiac
 - **arrhythmias** (PAC, PVC, SVT, VT)
 - mitral valve prolapse
 - valvular heart disease
 - hypertrophic obstructive cardiomyopathy
- Endocrine
 - thyrotoxicosis
 - pheochromocytoma
 - hypoglycemia
- Systemic
 - fever
 - anemia
- Drugs
 - tobacco, caffeine, alcohol, epinephrine, ephedrine, aminophylline, atropine
- Psychiatric
 - panic attack

Dyspnea

- Cardiovascular
 - acute MI
 - **CHF/LV failure**
 - aortic stenosis/mitral stenosis
 - cardiac tamponade
 - elevated pulmonary venous pressure
- Respiratory
 - airway disease
 - ♦ **asthma**
 - ♦ COPD exacerbation
 - ♦ upper airway obstruction (anaphylaxis, foreign body, mucus plugging)
 - parenchymal lung disease
 - ♦ ARDS
 - ♦ pneumonia
 - ♦ interstitial lung disease
 - pulmonary vascular disease
 - ♦ pulmonary embolism
 - ♦ pulmonary HTN
 - ♦ pulmonary vasculitis
 - pleural disease
 - ♦ pneumothorax
 - pleural effusion
- Neuromuscular and chest wall disorders
 - C-spine injury
 - polymyositis, myasthenia gravis, Guillain-Barré syndrome
 - kyphoscoliosis
- Anxiety/psychosomatic
- Severe anemia

Cardiac Diagnostic Tests

Electrocardiography (ECG) Basics

- the electrocardiogram (ECG) is a graphic representation of the electrical activity of the heart recorded from the surface of the body
- on the ECG graph
 - the horizontal axis represents time
 - 1 mm (1 small square) = 40 msec
 - 5 mm (1 large square) = 200 msec (at paper speed 25 mm/sec)
 - the vertical axis represents voltage
 - 1 mm (1 small square) = 0.1 mV
 - 10 mm (2 large squares) = 1 mV (at standard gain setting)
- leads
 - standard 12-lead ECG
 - limb leads: I, II, III, aVL, aVR, aVF
 - precordial leads: V1-V6 (V1-V2 septal, V3-V4 anterior, V5-V6 lateral)
 - additional leads
 - right-sided leads: V3R-V6R (useful in RV infarction and dextrocardia)
 - lateral = I, aVL, V5, V6; inferior = II, III, aVF; frontal = V1-V4

Overview of Diagnostic Tests

- Cardiac biomarkers (Tn, CK-MB) – in symptomatic state
- ECG – at rest, with stress, or in symptomatic state
- Echocardiography – at rest, or with stress
- Nuclear imaging – with stress
- Angiography (cardiac catheterization)
- CTA
- MRA/MRI

Figure 4. ECG Waveforms and Normal Values

Approach to ECGs

Rate

- normal = 60-100 bpm (atrial rate: 150-250 bpm = paroxysmal tachycardia, 250-350 bpm = atrial flutter, >350 bpm = atrial fibrillation)
- regular rhythm
 - to calculate the rate, divide 300 by number of large squares between 2 QRS complexes (there are 300 large squares in 1 minute: 300 x 200 msec = 60 sec)
 - or remember 300-150-100-75-60-50-43 (rate falls in this sequence with the number of additional large squares between QRS)
- irregular rhythm
 - rate = 6 x number of R-R intervals in 10 seconds (the "rhythm strips" are 10 second recordings)
 - types: wandering pacemaker, multifocal atrial tachycardia, atrial fibrillation
- atrial escape = 60-80 bpm; junctional escape = 40-60 bpm; ventricular escape = 20-40 bpm

Rhythm

- regular = R-R interval is the same across the tracing
- irregular = R-R interval varies across the tracing
 - regularly-irregular = repeating pattern of varying R-R intervals
 - irregularly irregular = R-R intervals vary erratically
- normal sinus rhythm (NSR)
 - P wave precedes each QRS; QRS follows each P wave
 - P wave axis is normal (positive in leads I, aVF)
 - rate between 60-100 bpm

Axis

- mean axis indicates the direction of the mean vector
- can be determined for any waveform (P, QRS, T)
- the standard ECG reported QRS axis usually refers to the mean axis of the frontal plane; it indicates the mean direction of ventricular depolarization forces
- QRS axis in the horizontal plane is not routinely calculated; it is directed posteriorly and to the left
 - the transition from negative to positive is usually in lead V3
- QRS axis in the frontal plane (see Figure 5)
 - normal axis: -30° to 90° (i.e. positive QRS in leads I and II)
 - left axis deviation (LAD): axis < -30°
 - right axis deviation (RAD): axis > 90°

Rate Calculations

- Examples
- Practice

Approach to ECGs Summary

- Rate
- Rhythm

Differential Diagnosis for Left and Right Axis Deviation

LAD	RAD
Left Ant. Hemiblock	RVH
Inferior MI	Left Post. Hemiblock
WPW	PE
RV Pacing	COPD
Normal Variant	Lateral MI
Elevated Diaphragm	WPW
Lead Misplacement	Dextrocardia
Endocardial cushion defect	Septal Defects

Figure 5. Axial Reference System

Each lead contains a (+) area displayed by the bold arrows. Impulses traveling toward the positive region of the lead results in an upward deflection in that lead. Normal QRS axis is between -30° and $+90^\circ$.

Intraventricular Conduction Abnormalities

Right Bundle Branch Block (RBBB)

Complete RBBB

- QRS duration >120 msec
- Positive QRS in lead V1 (rSR' or occasionally broad R wave)
- Broad S waves in leads I, V5-6 (>40 msec)
- Usually secondary T wave inversion in leads V1-2

Left Bundle Branch Block (LBBB)

Complete LBBB

- QRS duration >120 msec
- Broad notched or slurred R waves in leads I, aVL and usually V5 and V6
- Deep broad S waves in leads V1-2
- Secondary ST-T changes (-ve in leads with broad R waves, +ve in V1-2) are usually present
- LBBB usually masks ECG signs of myocardial infarction

Left Anterior Fascicular Block (LAFB) (Left Anterior Hemiblock)

- Left axis deviation (-30° to -90°)
 - Small q and prominent R in leads I and aVL
 - Small r and prominent S in leads II, III, and aVF

Left Posterior Fascicular Block (LPFB) (Left Posterior Hemiblock)

- Right axis deviation (110° to 180°)
 - Small r and prominent S in leads I and aVL
 - Small q and prominent R in leads II, III, and aVF

Bifascicular Block

- RBBB pattern
 - Small q and prominent R
- The first 60 msec (1.5 small squares) of the QRS shows the pattern of LAFB or LPFB
- Bifascicular block refers to impaired conduction in two of the three fascicles, most commonly a RBBB and left anterior hemiblock; the appearance on an ECG meets the criteria for both types of blocks

Figure 6. Complete LBBB, RBBB, LVH and RVH (only samples, please see online examples for the full range of waveforms and the text for additional characteristics)

Nonspecific Intraventricular Block

- QRS duration >120 msec
- absence of criteria for LBBB or RBBB

Hypertrophy and Chamber Enlargement

- left ventricular hypertrophy (LVH)
 - S in V1 + R in V5 or V6 >35 mm above age 40, (>40 mm for age 31-40, >45 mm for age 21-30)
 - R in aVL >11 mm
 - R in I + S in III >25 mm
 - additional criteria:
 - ♦ LV strain pattern (ST depression and T wave inversion in leads I, aVL, V4-V6)
 - ♦ left atrial enlargement
- right ventricular hypertrophy (RVH)
 - right axis deviation
 - R/S ratio >1 or qR in lead V1
 - RV strain pattern: ST segment depression and T wave inversion in leads V1-2
- left atrial enlargement (LAE)
 - biphasic P wave with the negative terminal component of the P wave in lead V1 ≥ 1 mm wide and ≥ 1 mm deep
 - P wave >120 msec, notched in lead II ("P mitrale")
- right atrial enlargement (RAE)
 - P wave >2.5 mm in height in leads II, III, or aVF ("P pulmonale")

Figure 7. LAE, RAE (only samples, please see online examples and text above for characteristics)

Ischemia/Infarction

- look for the anatomic distribution of the following ECG abnormalities (see Table 1)
- ischemia
 - ST segment depression
 - T wave inversion (most commonly in V1-V6)
- injury
 - transmural (involving the epicardium) – ST elevation in the leads facing the area injured/infarcted; transient ST elevation may occur in patients with coronary artery spasm (e.g. Prinzmetal angina) can be slight or prominent (>10 mm)
 - subendocardial – marked ST depression in the leads facing the affected area; it may be accompanied by enzyme changes and other signs of myocardial infarction; may also occur with angina

Figure 8. ECG Changes with Infarction

- evolving infarction (ST elevation in contiguous leads = acute MI)
- “typical” sequential changes of evolving myocardial infarction
 - 1st
 - ♦ hyperacute T waves (tall, symmetric T waves) in the leads facing the infarcted area, with or without ST elevation
 - 2nd
 - ♦ ST elevation (injury pattern) in the leads facing the infarcted area
 - ♦ usually in the first hours post infarct
 - ♦ in acute posterior infarction, there is ST depression in V1-V3 (reciprocal to ST elevation in the posterior leads, that are not recorded in the standard 12-lead ECG)
 - 3rd
 - ♦ significant Q waves: >40 msec or >1/3 of the total QRS (hours to days post-infarct)
 - 4th
 - ♦ inverted T waves (one day to weeks after infarction)
 - this classical sequence, however, does not always occur, e.g.
 - ♦ Q waves of infarction may appear in the very early stages, with or without ST changes
 - ♦ non-Q wave infarction: there may be only ST or T changes, despite clinical evidence of infarction
- completed infarction
 - abnormal Q waves (note that wide Q waves may be found in III and aVL in normal individuals)
 - ♦ duration >40 msec (>30 msec in aVF for inferior infarction)
 - ♦ Q/QRS voltage ratio is >33%
 - abnormal R waves (R/S ratio >1, duration >40 msec) in V1 and more frequently in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)

Significant ECG Changes

- Look for ST changes starting at 80 msec from J point
- J point = the junction between the QRS complex and the ST segment
- ST elevation: at least 1mm in 2 adjacent limb leads, or at least 1-2 mm in adjacent precordial leads
- ST depression: downsloping or horizontal
- Q wave: pathological if QRS ≥ 1 small square (≥ 40 msec) or >33% of the total QRS

Insignificant Q wave

Septal depolarization by the left bundle
Seen in leads I, II, III, aVL, V5, V6
<40 msec

Differential of ST Segment Changes

• ST Elevation

- Acute STEMI
- Ventricular Aneurysm
- LBBB
- Acute Pericarditis (diffuse changes)
- Ischemia w/reciprocal changes
- Post-MI
- Vasospastic (Prinzmetal's) angina
- Hypothermia (Osborne waves)
- Early repolarization (Normal variant; need old ECG's)

• ST Depression

- Acute NSTEMI or ischemia
- LVH or RVH with strain
- Post-MI
- STEMI with reciprocal changes
- Left or Right BBB
- Wolff-Parkinson-White syndrome

Table 1. Areas of Infarction(Q wave)/Ischemia (right dominant anatomy)

Vessel Usually Involved	Infarct Area (LAD and Circ)	Leads (LAD and Circ)
Left anterior descending (LAD)	Anteroseptal	V1, V2
	Anterior	V3, V4
	Anterolateral	I, aVL, V3-6
	Extensive anterior	I, aVL, V1-6
Right coronary artery (RCA)	Inferior	II, III, aVF
	Right ventricle	V3R, V4R (right sided chest leads)
	Posterior MI (assoc. with inf. MI)	V1, V2 (prominent R waves)
Circumflex	Lateral	I, aVL, V5-6
	Isolated posterior MI	V1, V2 (prominent R waves)

MISCELLANEOUS ECG CHANGES

Electrolyte Disturbances

- hyperkalemia (see Figure 9)
 - mild to moderate (K 5-7 mmol/L): tall peaked T waves
 - severe (K >7 mmol/L): progressive changes whereby P waves flatten and disappear, QRS widens and may show bizarre patterns, axis shifts left or right, ST shift with tall T waves
- hypokalemia (see Figure 10)
 - ST segment depression, prolonged QT interval, low T waves, prominent U waves (U>T)
 - enhances the toxic effects of digitalis
- hypercalcemia: shortened QT interval
- hypocalcemia: prolonged QT interval

Figure 9. Hyperkalemia (sinusoidal)

Figure 10. Hypokalemia

Low Voltage

- Definition: total QRS height in precordial leads <10 mm and limb leads <5 mm
- Differential diagnosis
 - Myocardial disease
 - ♦ Ischemia
 - ♦ Cardiomyopathy (usually infiltrative type), myocarditis
 - Pericardial effusion
 - Thick chest wall/barrel chest: COPD, obesity
 - Generalized edema
 - Hypothyroidism/myxedema
 - Inappropriate voltage standardization

Figure 11. Osborne J Waves of a Hypothermic Patient

Hypothermia

- sinus bradycardia
- when severe, prolonged QRS and QT intervals
- atrial fibrillation with slow ventricular response and other atrial/ventricular dysrhythmias
- Osborne J waves (see Figure 11): “hump-like” waves at the junction of the J point and the ST segment

Pericarditis

- early – diffuse ST segment elevation ± PR segment depression, upright T waves
- later – isoelectric ST segment, flat or inverted T waves
- low voltage if chronic constrictive pericarditis
- tachycardia

Drug Effects

- digitalis
 - therapeutic levels may be associated with “digitalis effect” (see Figure 12):
 - ♦ ST downsloping or “scooping”
 - ♦ T wave depression or inversion
 - ♦ QT shortening ± U waves
 - ♦ slowing of ventricular rate in atrial fibrillation
 - toxic levels associated with:
 - ♦ arrhythmias: paroxysmal atrial tachycardia (PAT) with conduction blocks, severe bradycardia in atrial fibrillation, accelerated junctional rhythms, PVCs, ventricular tachycardia (see *Arrhythmias*, C12)
 - ♦ “regularization” of ventricular rate in atrial fibrillation due to a junctional rhythm and AV dissociation
- amiodarone, quinidine, phenothiazines, tricyclic antidepressants, antipsychotics, some antihistamines, some antibiotics: prolonged QT interval, U waves

Figure 12. Atrial Fibrillation, ST Change due to Digitalis (“digitalis effect”)

Digitalis Side Effects

Palpitations, fatigue, visual changes (yellow vision), decreased appetite, hallucinations, confusion and depression.

Quinidine

- Wide P wave
- Wide QRS
- Prolonged QT
- ± ST depression
- ± U wave

Pacemakers

- Demand pacemaker has discharge (narrow vertical spike on ECG strip) prior to QRS
- Atrial pacemaker has discharge prior to P wave
- Triggered pacemaker has a discharge following the P wave but prior to the QRS
- Atrial and ventricular pacing have discharged before the P wave and QRS wave

Cardiac Biomarkers

- provide diagnostic and prognostic information and identify increased risk of mortality in acute coronary syndromes

Table 2. Cardiac Enzymes

Enzyme	Peak	Duration Elevated	DDx of Elevation
Troponin I, Troponin T	1-2 days	Up to 2 weeks	MI, CHF, AF, acute pulmonary embolism, myocarditis, chronic renal insufficiency, sepsis, hypovolemia
CK-MB	1 day	3 days	Myocardial infarction, myocarditis, pericarditis, muscular dystrophy, cardiac defibrillation, etc.

- check troponin I at presentation and 8h later \pm creatine kinase-MB (CK-MB, depends on local laboratory protocol)
- new CK-MB elevation can be used to diagnose reinfarction, troponin cannot
- other biomarkers of cardiac disease:
 - AST and LDH also increased in myocardial infarction (low specificity)
 - BNP and NT-proBNP – secreted by ventricles in response to increased end-diastolic pressure and volume
 - DDx: CHF, AF, PE, COPD exacerbation, pulmonary hypertension

Ambulatory ECG

- indications for outpatient management: palpitations, syncope, antiarrhythmic drug monitoring, and arrhythmia surveillance in patients with documented or potentially abnormal rhythms, surveillance of non-sustained arrhythmias that can lead to prophylactic intervention
- available technologies
 - Holter monitor
 - battery operated, continually records up to 3 leads for 24-48 hrs
 - symptoms recorded by patient on Holter clock for correlation with ECG findings
 - continuous loop recorder (diagnostic yield 66-83%)
 - worn continuously and can record data before and after patient activation for symptomatic episodes (usually worn for 2 weeks)
 - external and implantable devices
 - external devices can be transtelephonically downloaded
 - implantable loop recorder (ILR) – implanted subcutaneously to the right or left of the sternum; triggered by placing an activator over it; anterograde and retrograde recording time is programmable; cannot be transtelephonically downloaded; left in place for 14 to 18 months

Echocardiography

Transthoracic Echocardiography (TTE)

- ultrasound beams are directed across the chest wall to obtain images of the heart
- indications: evaluation of left ventricular ejection fraction (LVEF), wall motion abnormalities, myocardial ischemia and complications of MI, chamber sizes, wall thickness, valve morphology, proximal great vessels, pericardial effusion, unexplained hypotension, murmurs, syncope, congenital heart disease
- use with Doppler, which is used to quantify degree of valvular stenosis or regurgitation

Transoesophageal Echocardiography (TEE)

- ultrasound probe inserted into the esophagus to allow for better resolution of the heart and its structures
- better visualization of posterior structures, such as left atrium, mitral and aortic valves, interatrial septum
- invasive procedure, used to complement transthoracic echocardiography
- indications: intracardiac thrombi, tumours, valvular vegetations (infective endocarditis), aortic dissection, aortic atheromas, prosthetic valve function, shunts, technically inadequate transthoracic studies
- use with Doppler, which is used to quantify degree of valvular stenosis or regurgitation

Stress Echocardiography

- echocardiography in combination with either physiologic (exercise treadmill or bike testing) or pharmacologic (dobutamine infusion) stress
- validated in demonstrating myocardial ischemia and assessing viability
- provides information on the global left ventricular response to exercise
- regional wall motion is analyzed at rest and with stress
- used for valvular heart disease evaluation

Figure 13. Cardiac Enzymes

Use of B-Type Natriuretic Peptide in the Evaluation and Management of Acute Dyspnea (BASEL)

NEJM 2004; 350:647-54

Study: Prospective, randomized controlled trial.

Population: 452 patients (mean age 71 yrs. 58% male) with acute dyspnea; Patients with severe renal disease or cardiogenic shock were excluded.

Intervention: Assessment including measurement of B-type natriuretic peptide or standard assessment.

Outcome: Time to discharge and total cost of treatment.

Results: Median time to discharge was significantly shorter in the intervention group when compared with the control group (8.0 vs. 11.0 days, $p=0.001$). Total cost was also significantly lower in the intervention group (\$5410 vs. \$7264, $p=0.006$). In addition, the measurement of B-type natriuretic peptide significantly reduced the need for admission to hospital and intensive care. The 30-day mortality rates were similar (10% vs. 12%, $p=0.45$).

Conclusions: In patients with acute dyspnea, measurement of B-type natriuretic peptide improves clinical outcomes (need for hospitalization or intensive care) and reduces time to discharge and total cost of treatment.

Most Commonly Used Treadmill Stress Test Protocols

- **The Bruce Protocol** – 7 stage test with each stage lasting 3 minutes. With each successive stage, the treadmill increases in both speed and gradient.
- For older individuals or those with limited exercise capacity: either The Modified Bruce or The Modified Naughton Protocol

Important Contraindications to Exercise Testing

- Acute MI, aortic dissection, pericarditis, myocarditis, pulmonary embolism
- Severe AS, arterial HTN
- Inability to exercise adequately

Most Important Prognostic Factors in Exercise Testing

- ST depression
- ST elevation
- Inadequate blood pressure compensation

Duke Treadmill Score

Weighted index combining:

1. Treadmill exercise time using standard Bruce protocol
2. Maximum net ST segment deviation (depression or elevation)
3. Exercise-induced angina

Provides diagnostic and prognostic information (such as 1-year mortality)

Patients with normal perfusion studies at peak stress have a <1%/year incidence of death or nonfatal MI and are thus often spared further invasive evaluation for assessment of their symptoms.

ACC/AHA 2002 Guidelines for Use

Stable angina, baseline ECG abnormalities, post-revascularization assessment, heart failure, patients unable to exercise, preoperative risk assessment for patients undergoing noncardiac surgery.

Contrast Echocardiography

- contrast agents injected into the bloodstream to improve imaging of the heart
- conventional agent: agitated saline (contains microbubbles of air)
- allows visualization of right heart and intracardiac shunts, most commonly patent foramen ovale (PFO) and sometimes intrapulmonary shunt
- newer contrast agents are capable of crossing the pulmonary bed and achieving left heart opacification following intravenous injection; these contrast agents improve visualization of endocardial borders and enhance evaluation of ejection fraction

Stress Testing

- exercise testing is a cardiovascular stress test using treadmill or bicycle exercise with electrocardiographic and blood pressure monitoring
- guidelines for use:
 - patients with intermediate (10-90%) pretest probability of CAD based on age, gender and symptoms
 - complete RBBB
 - ST depression <1 mm at rest
- exercise test results stratify patients into risk groups:
 - low risk patients can be treated medically without invasive testing
 - intermediate risk patients may need additional testing in the form of exercise imaging studies or cardiac catheterization
 - high risk patients should be referred for cardiac catheterization

Indications for Terminating Exercise Stress Test

- drop in systolic blood pressure of >10 mmHg from baseline despite an increase in workload, when accompanied by other evidence of ischemia
- moderate to severe angina
- ST elevation (>1 mm) in leads without diagnostic Q-waves (other than V1 or aVR)
- increasing nervous system symptoms (e.g. ataxia, dizziness, or near syncope)
- signs of poor perfusion (cyanosis or pallor)
- technical difficulties in monitoring ECG or systolic blood pressure
- patient's desire to stop
- sustained ventricular tachycardia

Interpretation

- the most commonly used ECG criteria for a positive exercise test: ≥1 mm of horizontal or downsloping ST-segment depression or elevation (at least 60 to 80 msec after the end of the QRS complex)

NUCLEAR CARDIOLOGY

- myocardial perfusion imaging (MPI) with ECG-gated single photon emission computed tomography (SPECT), using radiolabelled tracer
- role in evaluating myocardial viability, detecting ischemia, and simultaneously assessing perfusion and left ventricular function
- the degree of severity shown on the scan reveals the likelihood of further cardiac event rates independent of the patient's history, examination, resting ECG, and stress ECG result
- often denoted as MIBI scan with reference to radiolabelled tracer used
- exercise
 - treadmill test (unless contraindicated)
- vasodilator stress with intravenous drugs
 - dipyridamole (Persantine®), adenosine
 - ♦ act to increase coronary flow by vasodilation of arterioles (the resistance vessels)
- images of the heart obtained during stress and at rest 3-4h later
 - fixed defect – impaired perfusion at rest and during stress (infarcted/hibernating)
 - reversible defect – impaired perfusion only during stress (ischemic)

Tracers

- thallium-201 (²⁰¹Tl, a K analogue)
- technetium-99 (⁹⁹Tc)-labelled tracer (sestamibi/Cardiolite® or hexamibi/Myoview®)

Summary of Stress Testing

- Exercise ECG
 - initial evaluation in patients without hard-to-interpret ECGs who are able to exercise
- Exercise Stress Echo
 - when ECG is uninterpretable
 - intermediate pre-test probability with normal/equivocal exercise ECG
 - post-ACS when used to decide on potential efficacy of revascularization
 - to evaluate the clinical significance of valvular heart disease

- Dobutamine Stress Echo
 - in patients unable to exercise, with the same indications as exercise stress echo
 - to assess tissue viability
- Exercise Myocardial Perfusion Imaging (MPI)
 - when ECG is uninterpretable
 - intermediate pre-test probability with normal/equivocal exercise ECG
 - in patients with previous imaging whose symptoms have changed
 - to diagnose ischemia
- Dipyridamole/Adenosine MPI
 - to diagnose CAD in possible ACS patients with non-diagnostic ECG and negative serum biomarkers
 - when ECG is uninterpretable due to LBBB or V-paced rhythm
 - in patients unable to exercise, with the same indications as exercise MPI

Sensitivity and Specificity of Various Stress Testing

Exercise ECG (Sn 68; Sp 77)
 Stress Echocardiography (Sn 76; Sp 88)
 PET scanning (Sn 91; Sp 82)
 MIBI scanning (Sn 88; Sp 77)

Cardiac Catheterization and Angiography

- invasive: catheters are introduced percutaneously into arterial and venous circulation under conscious sedation and contrast is injected
- arterial access most commonly through the femoral artery; radial approach gaining favour especially for obese patients and outpatients dependent on driving and ambulation (occupational requirements)
- venous access through the femoral vein or internal jugular vein
- same day procedure as outpatient:
 - indications for prehospitalization: anticoagulation therapy, renal failure, diabetes, contrast allergy
- catheterization permits direct measurement of intracardiac pressures, transvalvular and mean peak pressure gradients, valve areas, cardiac output, shunt data, oxygen saturations, and visualization of coronary arteries, cardiac chambers and great vessels

Right Heart Catheterization (Swan-Ganz catheter)

- right atrial, right ventricular, pulmonary artery pressures are recorded
- Pulmonary Capillary Wedge Pressure
 - obtained by advancing the catheter to wedge into the distal pulmonary artery
 - ♦ records pressures measured from the pulmonary venous system
 - ♦ in the absence of pulmonary venous disease, will reflect left atrial pressure

Left Heart Catheterization

- systolic and end-diastolic pressure tracings recorded; left ventricular size, wall motion and ejection fraction can be assessed by injecting contrast into the left ventricle (left ventriculography)
- cardiac output (measured by the Fick oxygen method or the indicator dilution method)

Coronary Angiography

- coronary vasculature accessed via the coronary ostium
- contraindicated with severe renal failure (due to contrast agent toxicity), must check renal status

Figure 14. Coronary Angiogram Schematic (RCA = right coronary artery, AM = acute marginal, LAD = left anterior descending, OM = obtuse marginal)

Prognosticators

- angiographic variables may provide valuable information regarding lesion severity, complexity, location and prognosis

ACC/AHA 2002 Recommended Indications for Coronary Angiography

- Disabling (CCS classes III and IV) chronic stable angina despite medical therapy
- High-risk criteria on clinical assessment or non-invasive testing
- Sudden cardiac death, serious ventricular arrhythmia, or CHF
- Uncertain diagnosis or prognosis after non-invasive testing
- Inability to undergo non-invasive testing

Coronary Angiography

Gold standard for localizing and quantifying CAD.

Hemodynamically significant stenosis is defined as 70% or more narrowing of the luminal diameter.

Diagnostic Catheterization

- outcomes related to complications for diagnostic catheterization should be <1%
- procedure related complications: vascular injury, renal failure, stroke, MI
 - mortality rate 0.1-0.2%
- inadequate diagnostic procedures should occur in far fewer than 1% of cases
- provocative pharmacological agents can be used to unmask pathology
 - fluid loading may unmask latent pericardial constriction
 - afterload reduction or inotropic stimulation may be used to increase the outflow tract gradient in hypertrophic cardiomyopathy
 - coronary vasoreactive agents (e.g. methylergonovine, acetylcholine)
 - a variety of pulmonary vasoreactive agents in primary pulmonary hypertension (e.g. oxygen, calcium channel blockers, adenosine, nitric oxide, or prostacyclin)

Contrast-Enhanced CT Coronary Angiography

- fast ECG-synchronized multi-slice CT image acquisition in the heart has enabled non-invasive imaging of the coronary arterial tree
- often used to assess coronary artery and previous graft stenosis/viability that could not be seen during coronary angiography
- sensitivity = 85%, specificity = 90% for the diagnosis of obstructive coronary disease with >50% stenosis

Magnetic Resonance Imaging (MRI)

- offers high spatial resolution, eliminates the need for iodinated contrast, and does not involve exposure to ionizing radiation
- valuable in assessment of congenital cardiac anomalies, abnormalities of the aorta, and assessment of viable myocardium

CARDIAC DISEASE**Arrhythmias****Mechanisms of Arrhythmias****(I) Alterations in Impulse Formation**

This can occur due to:

A. Abnormal Automaticity

- automaticity is a property of certain cardiomyocytes to depolarize themselves to their threshold voltage so as to spontaneously generate action potentials in a rhythmical fashion
- under normal circumstances, only cells at the specialized conduction system (SAN, AVN and ventricular conduction system) exhibit natural automaticity and are thus **pacemaking** cells – the automaticity of these pacemakers can either become abnormally increased or decreased
- cells in the myocardium outside the conduction system in disease (e.g. post-MI ventricular ischemia) may inappropriately acquire the property of automaticity and contribute to abnormal depolarization. If these ectopic generators depolarize at a rate that is greater than the SAN, they assume pacemaking control and become the source of abnormal rhythm
- automaticity can be influenced by:
 - ♦ neurohormonal tone (sympathetic and parasympathetic stimulation)
 - ♦ abnormal metabolic conditions (hypoxia, acidosis, hypothermia)
 - ♦ electrolyte abnormalities
 - ♦ drugs (e.g. digitalis)
 - ♦ local ischemia/infarction
 - ♦ other cardiac pathology
- this mechanism is responsible for the accelerated idioventricular rhythm and ventricular tachycardia that often occurs 24 to 72 hours post myocardial infarction

B. Triggered Activity due to Afterdepolarizations

There are two types of triggered activity:

1. Early Afterdepolarizations

- occur in the context action potential prolongation
- consequence of the membrane potential becoming more positive during repolarization
- result in self-maintaining depolarizing oscillations of action potential, generating a tachyarrhythmia
- basis for the degeneration of QT prolongation, either congenital or acquired, into Torsades de Pointes

2. Delayed Afterdepolarizations

- occur after the action potential has fully repolarized, but before the next usual action potential, thus called a delayed afterdepolarization
- commonly occurs in situations of high intracellular calcium (digitalis intoxication, ischemia) or during enhanced catecholamine stimulation

(II) Alterations in Impulse Conduction

This can occur due to:

A. Re-Entry Circuits (see Figure 15 for detailed description)

- the presence of self-sustaining re-entry circuit causes rapid repeated depolarizations in a region of myocardium
 - ♦ e.g. myocardium that has infarcted and become ischemic will consist of non-excitable and partially excitable zones which will promote the formation of re-entry circuits

Figure 15. Mechanism of Reentry

Requires both unidirectional block (1) and slowed retrograde conduction (2). When an action potential reaches a division in the conduction path (anywhere in the myocardium), the impulse proceeds around and stimulates distal myocardium. If the action potential propagates through a block (refractory tissue) in the retrograde direction but not in the forward direction, unidirectional block is present (1). This can occur as a result of cellular dysfunction with changes in cellular refractoriness. Slowed retrograde conduction of the action potential through B (dotted line) encounters excitable tissue in A because these myocytes have had sufficient time to repolarise by this time point, and now the impulse is free to excite A again thus generating a reentry circuit.

B. Conduction Block

- ischemia, fibrosis, trauma and drugs can cause transient, permanent, unidirectional or bidirectional block
- most common cause of block is due to refractory myocardium (cardiomyocytes are in refractory period or zone of myocardium unexcitable due to fibrosis)
- if block occurs along the specialized conduction system, distal zones of the conduction system can assume pacemaking control
- conduction block can not only lead to bradycardia, but also tachycardia when impaired conduction leads to re-entry phenomenon

C. Bypass Tracts

- normally the only conducting tract from the atria to the ventricles is the AVN
- congenital development of additional, or accessory conducting tracts bypass the AVN and facilitate premature ventricular activation before normal AVN conduction
- see *Pre-Excitation Syndromes*, C19

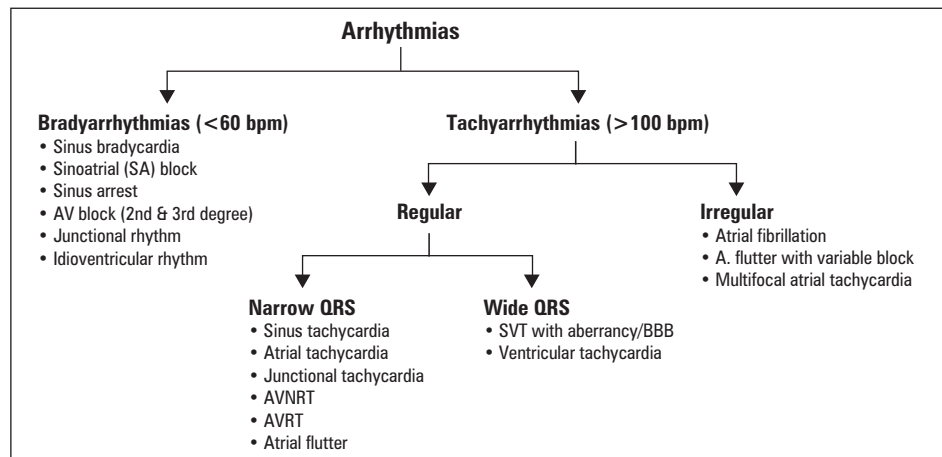

Figure 16. Clinical Approach to Arrhythmias

Bradyarrhythmias

- Examples

Sinus Arrhythmia

Normal P Waves, with variation of the P-P interval by >120 msec due to varying rate of SA node

"Respiratory SA":

- Seen more often in young adults (<31 years old)
- Normal, results from changes in autonomic tone during respiratory cycle
- Rate increases with inspiration, slows with expiration

"Non-respiratory SA":

- Seen more often in the elderly
- Can occur in the normal heart; if marked, may be due to sinus node dysfunction (e.g. in heart disease, or after digitalis toxicity)
- Usually does not require treatment

Bradyarrhythmias

SA NODAL DYSFUNCTION

Sinus Bradycardia

- P axis normal (P waves positive in I and aVF)
- rate <60 bpm
- marked sinus bradycardia (<50 bpm) may be seen in normal adults, particularly athletes, and in elderly individuals
- caused by
 - increased vagal tone or vagal stimulation
 - vomiting
 - episodes of myocardial ischemia or infarction (inferior MI)
 - sick sinus node
 - increased intracranial pressure
 - hypothyroidism
 - hypothermia
 - drugs (beta-blockers, calcium blockers, etc.)
- treatment: if symptomatic, atropine during acute episodes; pacing for sick sinus node syndrome; if drug-induced, reduction or withdrawal of drugs

Sinus Block, Pause, and Arrest

- three disorders involving the SA node; the sinus pacemaker fires but impulse fails to depolarize the atrial myocardium, resulting in no initial P wave (and consequently no QRS complex, ST segment or T wave)
- sinus block: also SA block, a complete block or failure of the sinus node to depolarize the atria; the block can last one or more cardiac cycles and is a multiple of the normal P-P interval
- sinus pause: a delay in the formation of a sinus impulse in the SA node, resulting in a temporary pause (usually >3 sec)
- sinus arrest: a longer delay in the formation of a sinus impulse in the SA node
 - there is no clear cut-off between sinus pause vs. arrest, however, if the pause lasts greater than 3x the normal P-P interval, then it may be called an arrest
 - the P-P prolongation is not phasic or gradual (unlike sinus arrhythmia) and is not a multiple of the normal P-P interval (unlike sino-atrial block)
- escape beats or rhythm may occur:
 - atrial escape: P waves with abnormal morphology
 - junctional escape: P waves not seen, or follow the QRS (retrograde P), rate 40-60 bpm
 - ventricular escape: no P wave; wide, abnormal QRS; slow rate 20-40 bpm

Sick Sinus Syndrome (SSS)

- characterized by sinus node dysfunction (marked bradycardia, sinus pause/arrest, sinoatrial block)
 - when symptomatic, electronic pacemaker is indicated
- frequently associated with episodes of atrial tachyarrhythmias ("tachy-brady syndrome")
- usually require a combination of a pacemaker for bradycardia and medications (beta-blocker, calcium channel blocker, and/or digoxin, initiated after pacemaker insertion) for tachycardia

AV Conduction Blocks

1st Degree AV Block

- prolonged PR interval (>200 msec)
- frequently found among otherwise healthy adults
- no treatment required

2nd Degree AV Block

- some of the atrial impulses are not conducted to the ventricles
- can describe block by ratio of P waves to # of QRS (e.g. 2:1, 3:1, 4:1 increases in severity)
- second degree AV block is further subdivided into:
 - Type I (Mobitz I) 2nd Degree AV Block
 - ♦ a gradual prolongation of the PR interval precedes the failure of conduction of a P wave (Wenckebach phenomenon)
 - ♦ AV block is usually in AV node (proximal)
 - triggers (usually reversible): increased vagal tone (eg. following surgery), RCA-mediated ischemia
 - not an indication for temporary or permanent pacing

Figure 17. Second Degree AV Block with Wenckebach Phenomenon (Mobitz I) (4:3 conduction) (Lead V₁)

- Type II (Mobitz II) 2nd Degree AV Block
 - ♦ the PR interval is constant; there is an abrupt failure of conduction of a P wave
 - ♦ AV block is usually distal to the AV node (ie. His bundle)
 - ♦ increased risk of high grade or 3rd degree AV block

Figure 18. Second Degree AV Block (Mobitz II) (3:2 conduction) (Lead V₁)

Type II (Mobitz II)
2° Type II AV block is an indication for permanent pacing.

2:1 AV Block

- often not possible to determine whether the block is type I or type II
- prolonged or repeated recordings may clarify the diagnosis

Figure 19. 2:1 AV Block (Lead II)

3rd Degree AV Block

- complete failure of conduction of the supraventricular impulses to the ventricles
- ventricular depolarization initiated by an escape pacemaker distal to the block
- QRS can be narrow or wide (junctional vs. ventricular escape rhythm)
- PP and RR intervals are constant, variable PR intervals
- no relationship between P waves and QRS complexes (P waves “marching through”)
- management (see *Electrical Pacing*, C21)

Figure 20. Third Degree AV Block (Complete Heart Block) (Lead II)

Tachyarrhythmias

- Examples

Supraventricular Tachyarrhythmias

Presentation for SVT (and pre-excitation syndromes)

- symptoms can include: palpitations, dizziness, dyspnea, chest discomfort, presyncope/syncope
- may precipitate congestive heart failure (CHF), hypotension, or ischemia in patients with underlying disease
- untreated tachycardias can cause cardiomyopathy (rare, potentially reversible with treatment of SVT's)
- includes supraventricular and ventricular rhythms

Supraventricular Tachyarrhythmias (SVT)

- tachyarrhythmias that originate in the atria or AV junction
- this term is used when a more specific diagnosis of mechanism and site of origin cannot be made
- characterized by narrow QRS, unless there is pre-existing BBB or aberrant ventricular conduction (abnormal conduction due to a change in cycle length)

Sinus Tachycardia

- sinus rhythm with rate >100 bpm
- occurs in normal subjects with increased sympathetic tone (exercise, emotions, pain), alcohol use, caffeinated beverages, drugs (e.g. beta-adrenergic agonists, anticholinergic drugs, etc.)
- etiology: fever, hypotension, hypovolemia, anemia, thyrotoxicosis, heart failure, MI, shock, pulmonary embolism, etc.
- treatment: treat underlying disease; consider beta-blocker if symptomatic, CCB if beta-blockers contraindicated

Premature Beats

- premature atrial contraction (PAC, Figure 25)
 - ectopic supraventricular beat originating in the atria
 - P wave morphology of the PAC usually differs from that of a normal sinus beat
- junctional premature beat
 - ectopic supraventricular beat that originates in the vicinity of the AV node
 - P wave is usually not seen or an inverted P wave is seen and may be before or closely follow the QRS complex
 - treatment usually not required

Atrial Flutter

Figure 21. Atrial Flutter with Variable Block

- rapid, regular atrial depolarization from a macro re-entry circuit within the atrium (most commonly the right atrium)
- atrial rate 250-350 bpm, usually 300 bpm
- AV block usually occurs; it may be fixed (2:1, 3:1, 4:1, etc.) or variable
- etiology: CAD, thyrotoxicosis, MV disease, cardiac surgery, COPD, pulmonary embolism, pericarditis
- ECG: sawtooth flutter waves (most common type of flutter) in inferior leads (II, III, aVF); narrow QRS (unless aberrancy)
- in atrial flutter with 2:1 block, carotid sinus massage (first check for bruits), Valsalva maneuver or adenosine may decrease AV conduction and bring out flutter waves
- treatment
 - acute: if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
 - if stable
 - (1) rate control: beta-blocker, diltiazem, verapamil, or digoxin
 - (2) chemical cardioversion: sotalol, amiodarone, type I antiarrhythmics or electrical cardioversion
 - anticoagulation guidelines same as for patients with AF (see *Atrial Fibrillation*, C17)
 - long-term: antiarrhythmics, catheter radiofrequency (RF) ablation (success rate dependent on site of origin of atrial flutter)

Multifocal Atrial Tachycardia (MAT)

- irregular rhythm caused by presence of 3 or more atrial foci (may mimic AF)
- atrial rate 100-200 bpm; at least 3 distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
- occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline or digitalis toxicity
- treatment: treat the underlying cause; CCBs may be used (e.g. diltiazem, verapamil), beta-blockers may be contraindicated because of severe pulmonary disease
- no role for electrical cardioversion, antiarrhythmics or ablation

Atrial Fibrillation (AF)

- most common sustained arrhythmia
- incidence increases with age (10% of population >80 years old)
- symptoms: palpitations, fatigue, syncope and may precipitate or worsen heart failure
- may be associated with thromboembolic events (4%/year in nonvalvular AF)
- **initiation**
 - single circuit re-entry and/or ectopic foci act as aberrant generators producing atrial tachycardia (350-600)
 - impulses then conduct irregularly across the atrial myocardium to give rise to fibrillation
 - in some cases, ectopic foci have also been mapped to the pulmonary vein ostia and can be ablated
- **maintenance**
 - the tachycardia causes atrial structural and electrophysiological remodelling changes that further promote AF; thus the longer the patient is in AF, the more difficult it is to convert back to sinus rhythm
- **consequences**
 - the AV node irregularly filters incoming atrial impulses producing an irregular ventricular response of <200 bpm and the tachycardia leads to suboptimal cardiac output
 - fibrillatory conduction of the atria promotes blood stasis increasing the risk of thrombus formation – AF is an important risk factor for stroke

Table 3. CHADS2 Risk Prediction for Non-Valvular AF

Risk Factor	Points	CHADS2 Score	Stroke Risk (%/Yr)	Anticoagulation Recommendation
Congestive Heart Failure	1	0-1	1.9-2.8 (low)	aspirin 81-325 mg daily
Hypertension	1	2-3	4.0-5.9 (mod)	coumadin (INR 2-3)
Age >75	1	4-6	8.5-18.2 (high)	coumadin (INR 2-3)
Diabetes	1			
Stroke/TIA (prior)	2			

JAMA 2001; 285(22):2864-70

AF on ECG

- no organized P waves due to rapid atrial activity (350-600 bpm) causing a chaotic fibrillatory baseline
- irregularly irregular ventricular response (typically 100-180bpm), narrow QRS (unless aberrancy or previous BBB)
- wide QRS complexes due to aberrancy may occur following a long-short cycle sequence (“Ashman phenomenon”)
- loss of atrial contraction, thus no “a” wave seen in JVP, no S4 on auscultation

**Figure 22. Atrial Fibrillation (Lead II)****Management (adapted from ACC/AHA/ESC guidelines 2006)****Major objectives (RACE)**

1. Rate control: beta-blockers, diltiazem, verapamil (in patients with heart failure: digoxin, amiodarone)
2. Anti-coagulation: prevent thromboembolism
 - assess stroke risk: determine CHADS2 score in patients with nonvalvular AF
 - if no risk factors, ASA 81-325 mg daily
 - 1 moderate risk factor, ASA or warfarin (INR 2.0-3.0, target 2.5)
 - ≥2 moderate risk factors or any high risk factor (prior stroke, TIA or embolism, mitral stenosis, prosthetic valve), warfarin
3. Cardioversion (electrical)
 - if AF <24-48 hrs, can usually cardiovert without anticoagulation
 - if AF >24-48 hrs, anticoagulate for 3 weeks prior and 4 weeks after cardioversion
 - if patient unstable (hypotensive, active angina due to tachycardia, uncontrolled heart failure), should cardiovert immediately
4. Etiology
 - HTN, CAD, valvular disease, pericarditis, cardiomyopathy, myocarditis, ASD, following surgery, PE, COPD, thyrotoxicosis, SSS (Sick Sinus Syndrome), alcohol (“holiday heart”)
 - may present in young patients without demonstrable disease (“lone AF”) and in the elderly without underlying heart disease
 - restore normal sinus rhythm if feasible

Atrial Fibrillation – AFFIRM Trial

NEJM 2002; 347:1825-33

Study: Randomized, multicenter trial with mean follow-up of 3.5 years.**Population:** 4060 patients (mean age 70 yrs, 61% male, 89% white) with atrial fibrillation and a high risk of stroke or death.**Intervention:** Rate control (β-blockers, calcium channel blockers, or digoxin alone or in combination) vs. rhythm control (antiarrhythmic drug chosen by the treating physician).**Primary Outcome:** All cause mortality.**Results:** There was no difference in mortality – or composite mortality, disabling stroke, disabling anoxic encephalopathy, major bleeding, and cardiac arrest – between the two groups. There were more incidents of hospitalizations (80.1% vs. 73%, $p < 0.001$) and adverse events (Torsades de pointes (12 vs. 2, $p = 0.007$), pulseless or bradycardic arrest (9 vs. 1, $P = 0.01$), pulmonary event (108 vs. 24, $p < 0.001$) gastrointestinal event (127 vs. 35, $p < 0.001$), prolonged QT interval (31 vs. 4, $p \leq 0.001$), bradycardia (105 vs. 64, $p = 0.001$) in the rhythm-control group. Decreased risk of death in the rate control arm in sub-groups.**Conclusion:** Rate-control was as effective as rhythm-control in atrial fibrillation and is better tolerated. There were more hospitalizations, incidents in the rhythm-control group.

Oral Anticoagulants versus Antiplatelet Therapy for Preventing Stroke in Patients with Non-Valvular Atrial Fibrillation and No History of Stroke or Transient Ischemic Attacks

Cochrane Database Syst Rev 2007; (3):CD006186
Study: Cochrane Systematic Review. 8 RCTs with mean 1.9 years of follow-up.

Population: 9598 total patients with non-valvular atrial fibrillation and no history of stroke or transient ischemic attack.

Intervention: Long-term adjusted-dose warfarin versus aspirin

Outcome: All cause mortality, all stroke, vascular death, myocardial infarctions.

Results: Dose-adjusted warfarin therapy significantly reduced all stroke (OR 0.68, 95%CI 0.54 – 0.85), ischemic stroke (OR 0.53, 95%CI 0.41 – 0.68), and systemic emboli risk (OR 0.48, 95%CI 0.25 – 0.90). There was no significant difference in disabling or fatal strokes, MI, vascular death, or all cause mortality. There was a significantly increased risk of intracranial hemorrhage with warfarin therapy versus aspirin (OR 1.98, 95%CI 1.20 – 3.28).

Conclusion: Long-term adjusted-dose warfarin significantly reduces all stroke and embolic risks but does not reduce risk of disability or mortality and carries a significant intracranial hemorrhage risk. The threshold of benefit for anti-coagulation versus anti-platelet therapy remains controversial.

Additional Management Points Regarding Atrial Fibrillation

- recent studies of patients with atrial fibrillation suggest that there is no difference in long-term survival when treating patients with a rhythm-control versus rate-control strategy
- however, many patients with a significant underlying structural heart lesion (e.g. acute MI, history of congestive heart failure), valvular lesions (mitral stenosis, mitral regurgitation, aortic stenosis), hypertrophic cardiomyopathy, cardiac amyloid, other cardiomyopathies, pericardial disease, congenital heart lesions) will not tolerate atrial fibrillation well (since many dependent on atrial kick) and these patients should be cardioverted (chemical or electrical) as soon as possible

Newly Discovered AF

- anticoagulants may be beneficial if high risk for stroke
- if the episode is self limited and not associated with severe symptoms, no need for antiarrhythmic drugs
- if AF persists, 2 options:
 - rate control and anticoagulation (as indicated above)
 - cardioversion (as above)

Recurrent AF/Permanent AF

- if episodes are brief or minimally symptomatic, antiarrhythmic drug may be avoided; rate control and anticoagulation are appropriate
- patients who have undergone at least one attempt to restore sinus rhythm may remain in AF after recurrence: permanent AF may be accepted (with rate control and antithrombotics as indicated by CHADS2 score) in certain clinical situations
- if symptoms are bothersome or episodes are prolonged, antiarrhythmic drugs should be used
 - no or minimal heart disease: flecainide, propafenone or sotalol
 - LV dysfunction: amiodarone
 - CAD: beta-blockers, amiodarone

AV Nodal Re-Entrant Tachycardia (AVNRT)

- re-entrant circuit using the dual pathways (fast conducting beta fibres and slow conducting alpha fibres) within or near the AV node; often found in the absence of structural heart disease; cause is commonly idiopathic, although familial AVNRT has been reported
- sudden onset and offset
- fast regular rhythm; rate 150-250 bpm
- usually initiated by a supraventricular or ventricular premature beat
- AVNRT accounts for 60-70% of all paroxysmal SVTs
- retrograde P waves may be seen but are usually lost in the QRS complex
- treatment
 - acute: Valsalva or carotid massage, adenosine is first choice if unresponsive to vagal maneuvers; if no response, try metoprolol, digoxin, diltiazem; electrical cardioversion if patient hemodynamically unstable (hypotension, angina or CHF)
 - long-term: 1st line: beta-blocker, diltiazem, digoxin, 2nd: anti-arrhythmic drugs (flecainide, propafenone), 3rd: catheter ablation

The carotid massage is actually a constant pressure directed posteriorly against the carotid artery for 5-10 seconds. Always listen for bruits before palpation.

Figure 23. Mechanism for AV Nodal Re-Entry

Pre-Excitation Syndromes

- refer to a subset of supraventricular tachyarrhythmias, mediated by an accessory pathway, which can lead to ventricular pre-excitation

Wolff-Parkinson-White (WPW) Syndrome

- congenital defect present in 1.5-2/1000 of the general population
- an accessory conduction tract (Bundle of Kent; can be in right or left atrium) abnormally allows early electrical activation of part of one ventricle
- impulses travel at a greater conduction velocity across the Bundle of Kent thereby effectively 'bypassing' AV node
- since the ventricles are activated earlier, the ECG shows early ventricular depolarization in the form of initial slurring of the QRS complex – the so called delta wave
- atrial impulses that conduct to the ventricles through both the Bundle of Kent and the normal AV node/His-Purkinje system generate a broad "fusion complex"
- ECG features of WPW
 - PR interval <120 msec
 - "delta wave": slurred upstroke of the QRS (the leads with the delta wave vary with site of bypass)
 - widening of the QRS complex due to the premature activation
 - secondary ST segment and T wave changes
 - tachyarrhythmias may occur, most often AVRT and AF

Figure 24. Accessory pathway conduction in WPW causes early ventricular activation leading to the appearance of a delta wave (slurred upstroke of the QRS) on the ECG before usual conduction occurs across the AVN

AF in WPW Patients

- AF is the index arrhythmia in up to 20 percent of patients with WPW syndrome
 - it is usually intermittent rather than persistent or permanent
- rapid atrial depolarizations in AF are conducted through the bypass tract which is not able to filter impulses like the AVN
- consequently, the ventricular rate becomes extremely rapid (>200 bpm) and the QRS complex widens
- treatment: electrical cardioversion, IV procainamide or IV amiodarone
 - do not use drugs that slow AV node conduction (digoxin, beta blockers) as this may cause preferential conduction through the bypass tract and then precipitate VF
 - long-term: ablation of bypass tract when possible

AV Re-Entrant Tachycardia (AVRT)

- re-entrant loop via accessory pathway and normal conduction system
- initiated by a premature atrial or ventricular complex
- orthodromic AVRT: stimulus from a premature complex travels up the bypass tract (V to A) and down the AV node (A to V) with narrow QRS complex (no delta wave because stimulus travels through normal conduction system)
 - comprises 95 percent of the reentrant tachycardias associated with WPW syndrome
- antidromic AVRT: more rarely the stimulus goes up the AV node (V to A) and down the bypass tract (A to V); wide and abnormal QRS as ventricular activation is only via the bypass tract
- treatment
 - acute: similar to AVNRT except avoid long-acting AV nodal blockers, e.g. digoxin and verapamil
 - long-term: for recurrent arrhythmias, ablation of the bypass tract is recommended
 - ♦ drugs such as flecainide and procainamide can be used

Ventricular Tachyarrhythmias

Premature Ventricular Contraction (PVC) or Ventricular Premature Beat (VPB)

- QRS width >120 msec, no preceding P wave, bizarre QRS morphology
- origin: LBBB pattern = RV site; RBBB pattern = LV site
- PVCs may be benign but are usually significant in the following situations:
 - consecutive ($\geq 3 = VT$) or multifocal (varied origin)
 - PVC falling on the T wave of the previous beat ("R on T phenomenon"): may precipitate ventricular tachycardia or VF

Accelerated Idioventricular Rhythm

- ectopic ventricular rhythm with rate 50-100 bpm
- more frequently occurs in the presence of sinus bradycardia, and is easily overdriven by a faster supraventricular rhythm
- frequently occurs in patients with acute myocardial infarction or other types of heart disease (cardiomyopathy, hypertensive, valvular) but it does not affect prognosis and does not usually require treatment

Figure 25. PVC (with bigeminy pattern) and PAC

Arrhythmias that May Present as a Wide QRS Tachycardia

- Ventricular tachycardia
- SVT with aberrant conduction (rate related)
- SVT with preexisting BBB or nonspecific intraventricular conduction defect
- AV conduction through a bypass tract in WPW patients during an atrial tachyarrhythmia (e.g. atrial flutter, atrial tachycardia)
- Antidromic AVRT in WPW patients (see *Pre-excitation Syndromes*, C19)

Ventricular Tachycardia (VT)

- 3 or more consecutive ectopic ventricular complexes (Figure 26)
 - rate >100 bpm (usually 140-200)
 - ventricular flutter: if rate >200 bpm and complexes resemble a sinusoidal pattern
 - “sustained VT” if it lasts longer than 30 sec
 - ECG characteristics: wide regular QRS tachycardia (QRS usually >140 msec); AV dissociation; bizarre QRS pattern. Also favour Dx of VT: left axis or right axis deviation, nonspecific intraventricular block pattern, monophasic or biphasic QRS in V1 with RBBB, QRS concordance in V1-V6
 - occasionally during VT supraventricular impulses may be conducted to the ventricles generating QRS complexes with normal or aberrant supraventricular morphology (“ventricular capture”) or summation pattern (“fusion complexes”)
- **monomorphic VT**
 - identical complexes with uniform morphology
 - more common than polymorphic VT
 - typically result from intraventricular re-entry circuit
 - potential causes: chronic infarct scarring, acute MI/ischemia, cardiomyopathies, myocarditis, arrhythmogenic right ventricular dysplasia, idiopathic, drugs (e.g. cocaine), electrolyte disturbances
- **polymorphic VT**
 - complexes with constantly changing morphology, amplitude, and polarity
 - more frequently associated with hemodynamic instability due to faster rates (typically 200-250 bpm) vs. monomorphic VT
 - potential causes: acute myocardial infarction, severe or silent ischemia, and predisposing factors for QT prolongation (see below in Torsades de Pointes)
- treatment
 - sustained VT (longer than 30 seconds) is an emergency, requiring immediate treatment
 - hemodynamic compromise – electrical cardioversion
 - no hemodynamic compromise – electrical cardioversion, lidocaine, amiodarone, type Ia agents (procainamide, quinidine)

Figure 26. Ventricular Tachycardia (Monomorphic)

Table 4. Wide Complex Tachycardia: Clues for Differentiating VT vs. SVT with Aberrancy*

Clinical Clues		ECG Clues	
Presenting symptoms	Not helpful	AV dissociation	VT
History of CAD and previous MI	VT	Capture or fusion	VT
Physical Exam		QRS width >140 msec	VT
Cannon “a” waves	VT	Extreme axis deviation	VT
Variable S1	VT	(left or right superior axis)	
Carotid sinus massage/adenosine terminates arrhythmia	SVT**	Positive QRS concordance (R wave across chest leads)	VT
		Negative QRS concordance (S wave across chest leads)	May suggest VT
		Axis shift during arrhythmia	VT (polymorphic)

*If patient >65 and previous MI or structural heart disease, then chance of VT >95%

**May terminate VT in some patients with no structural heart disease

Torsades de Pointes

- a variant of polymorphic VT that occurs in patients with baseline QT prolongation – “twisting of the points” (Figure 27)
- looks like usual VT except that QRS complexes “rotate around the baseline” changing their axis and amplitude
- ventricular rate greater than 100 bpm, usually 150-300 bpm
- etiology: patients with prolonged QT intervals are predisposed
 - congenital long QT syndromes
 - drugs – e.g. Class IA (quinidine), Class III (sotalol), phenothiazines (TCAs), erythromycin, quinolones, antihistamines
 - electrolyte disturbances – hypokalemia, hypomagnesemia
 - nutritional deficiencies causing above electrolyte abnormalities
- treatment: IV magnesium, temporary pacing, isoproterenol and correct underlying cause of prolonged QT, electrical cardioversion if hemodynamic compromise

Figure 27. Torsades de Pointes

Ventricular Fibrillation (VFib)

- chaotic ventricular arrhythmia, with very rapid irregular ventricular fibrillatory waves of varying morphology (Figure 28)
- terminal event, unless advanced cardiac life-support (ACLS) procedures are promptly initiated to maintain ventilation and cardiac output, and electrical defibrillation is carried out
- most frequent cause of sudden death
- refer to ACLS algorithm for complete therapeutic guidelines

Figure 28. Ventricular Fibrillation

Electrophysiology (EPS) Studies

- invasive test for the investigation and treatment of cardiac rhythm disorders using intracardiac catheters
- provide detailed analysis of the arrhythmia mechanism and precise site of origin when ECG data are nondiagnostic or unobtainable
- bradyarrhythmias: define the mechanisms of sinus node dysfunction and localize site of AV conduction block
- tachyarrhythmias: map for possible ablation or to assess inducibility of ventricular tachycardia

Electrical Pacing

- the decision to implant a pacemaker usually is based on symptoms of a bradyarrhythmia or tachyarrhythmia in the setting of heart disease

Pacemaker Indications

- SA node dysfunction (most common): symptomatic bradycardia \pm hemodynamic instability
 - common manifestations include: syncope, near syncope, transient lightheadedness, or severe fatigue
- SA node dysfunction is commonly caused by: intrinsic disease within the sinus node (e.g. idiopathic degeneration, fibrosis, ischemia, or surgical trauma), abnormalities in autonomic nervous system function, and drug effects
- AV nodal-infranodal block: Mobitz II, complete heart block

Pacing Techniques

- temporary: transvenous (jugular, subclavian, femoral) or external pacing
- permanent: transvenous into RA, apex of RV or both
 - can sense and pace atrium, ventricle or both
 - new generation: rate responsive, able to respond to physiologic demand
 - biventricular

Table 5. Pacemaker Nomenclature

Position I	Position II	Position III	Position IV	Position V
Chamber paced	Chamber sensed	Response to sensing	Programmability	Tachyarrhythmia control
O = None	O = None	O = None	O = None	O = None
A = Atrium	A = Atrium	I = Inhibited	R = Rate modulation	P = Pace
V = Ventricle	V = Ventricle	T = Triggered		S = Shock
D = Dual (A+V)	D = Dual (A+V)	D = Dual (I + T)		D = Dual (P+S)

- examples of commonly used pacemakers
 - VVI: single lead in ventricle, pacemaker inhibited in response to a sensed beat in ventricle; protect patient from bradycardia
 - DDD: separate leads in atrium and ventricle; pace atrium if atrium does not contract; once an atrial event has occurred (whether paced or native) device will ensure that ventricular contraction follows; device is inhibited in the presence of sinus rhythm and normal AV conduction, provides physiologic pacing

Systematic Review: Implantable Cardioverter Defibrillators for Adults with Left Ventricular Systolic Dysfunction

Ann Intern Med 2007; 147:251-62

Study: Meta-review of 12 RCTs used for Implantable Cardioverter Defibrillator (ICD) efficacy, 5 RCTs and 48 observational studies for effectiveness, and 21 RCTs and 43 observational studies for safety review.

Population: 8516 patients for ICD efficacy, 26 840 patients for effectiveness, and 86 809 patients for safety review with left ventricular ejection fraction ≤ 0.35 .

Intervention: Implantable Cardioverter Defibrillator implantation.

Outcomes: All-cause mortality and adverse events

Results: ICDs reduced all-cause mortality by 20% (95% CI, 10% - 29%; $I^2 = 44.4\%$) with greatest reduction (54%) in sudden cardiac death (CI, 37% - 63%; $I^2 = 0\%$). Observational studies had a reduced relative risk of 0.54 for all-cause mortality versus RCTs (CI 0.43 - 0.58, $I^2 = 60.4\%$). Rates of success of ICD implantation were 99% (CI 98.8% - 99.3%) with a 1.2% (CI 0.9% - 1.5%) chance of peri-implantation death. Post-implantation complications (per 100 patient-years) were: 1.4 (CI 1.2 - 1.6) device malfunctions; 1.5 (CI 1.3 - 1.8) lead problems; 0.6 (CI 0.5 - 0.8) implant site infection; and 19.1 (CI 16.5 - 22.0) inappropriate discharges in RCTs versus a rate of 4.9 (CI 4.5 - 5.3) inappropriate discharges in observational studies.

Conclusion: ICDs are safe and effective in reducing mortality in adult patients with LV systolic dysfunction, but carry significant risks of inappropriate discharges. Differences between RCTs and observational studies show that improved risk stratification of patients may further improve outcomes and reduce adverse events.

Implantable Cardioverter Defibrillators (ICDs)

- sudden cardiac death (SCD) usually results from ventricular fibrillation (VFib), sometimes preceded by monomorphic or polymorphic ventricular tachycardia (VT)
- ICDs detect ventricular tachyarrhythmias and are highly effective in terminating VT/VFib and in aborting SCD
- several studies demonstrate mortality benefit vs. antiarrhythmics in 2° prevention (AVID, CASH, CIDS)
- benefit for 1° prevention of SCD in patients with ischemic and non-ischemic cardiomyopathy, depressed left ventricular ejection fraction (LVEF), prolonged QRS
- see *Heart Failure*, C32 for current treatment recommendations

Catheter Ablation

Techniques

- radiofrequency (RF) energy: a low-voltage high-frequency form of electrical energy (similar to cautery). RF energy produces small, homogeneous, necrotic lesions approximately 5-7 mm in diameter and 3-5 mm in depth

Indications

- paroxysmal SVT
 - AVNRT: accounts for more than half of all cases
- accessory pathway (orthodromic reciprocating tachycardia): 30% of SVT
 - re-entrant rhythm, with an accessory AV connection as the retrograde limb
 - corrected by targeting the accessory pathway
- atrial flutter: flutter focus in RA
- atrial fibrillation: potential role for pulmonary vein ablation
- ventricular tachycardia: commonly arises from the right ventricular outflow tract and less commonly originates in the inferoseptal left ventricle near the apex (note: majority of cases of VT are due to scarring from previous MI and cannot be ablated)

Major Complications

- approximately 1% of patients
- death: 0.1-0.2%
- cardiac: high grade AV block requiring permanent pacemaker, tamponade, pericarditis
- vascular: hematoma, vascular injury, thromboembolism, TIA/stroke
- pulmonary: pulmonary embolism

Ischemic Heart Disease (IHD)

Epidemiology

- most common cause of cardiovascular morbidity and mortality
- atherosclerosis and thrombosis are the most important pathogenetic mechanisms
- male:female ratio = 2:1 with all age groups included (Framingham study), 8:1 for age <40 , 1:1 for age >70
- peak incidence of symptomatic IHD is age 50-60 (men) and 60-70 (women)
- for primary prevention of ischemic heart disease, please see [Family Medicine](#), FM17

Table 6. Risk Factors for Atherosclerotic Heart Disease

Major Risk Factors	Minor Risk Factors
Smoking	Male, postmenopausal female
Diabetes mellitus (DM)	Obesity
Hypertension (HTN)	Sedentary lifestyle
Family history (FHx) of MI	Hyperhomocysteinemia
First degree male relative <55	
First degree female relative <65	
Hyperlipidemia	

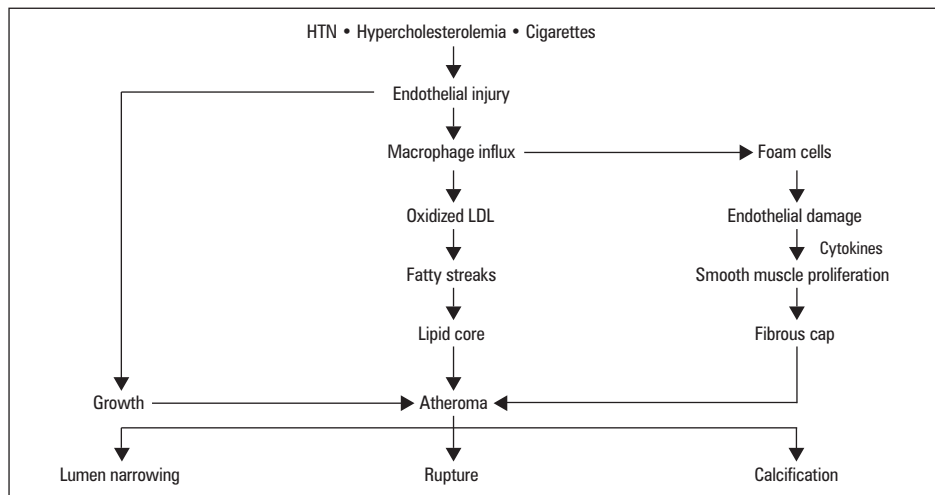

Figure 29. Pathophysiology of Atherosclerosis

Chronic Stable Angina

Definition

- symptom complex resulting from an imbalance between oxygen supply and demand in the myocardium
- factors influencing supply
 - luminal diameter (most important factor)
 - duration of diastole (important for coronary artery perfusion)
 - hemoglobin
 - SaO₂
- factors influencing demand
 - heart rate
 - contractility
 - wall stress

Etiology and Pathophysiology

- decreased myocardial oxygen supply
 - atherosclerosis, vasospasm
 - tachycardia (decreased duration of diastolic coronary perfusion)
 - anemia
 - hypoxemia
 - congenital anomalies
- increased myocardial oxygen demand
 - tachycardia
 - hyperthyroidism (increased contractility, increased HR)
 - myocardial hypertrophy, aortic stenosis

Signs and Symptoms

- typical: retrosternal chest pain, tightness or discomfort radiating to left (± right) shoulder/arm/neck/jaw, associated with diaphoresis, nausea, anxiety
- predictably precipitated by the “3 E’s”: Exertion, Emotion and Eating
- brief duration, lasting <10-15 minutes and typically relieved by rest and nitrates
- Levine’s sign: clutching fist over sternum when describing chest pain
- anginal equivalents: dyspnea, acute left ventricular failure, flash pulmonary edema

Clinical Assessment

- history, physical and directed risk factor assessment
- labs: Hb, fasting glucose, fasting lipid profile
- ECG (at rest and during episode of chest pain if possible)
- CXR (suspected heart failure, valvular disease, pericardial disease, aortic dissection/aneurysm, or signs or symptoms of pulmonary disease)
- stress testing (see *Cardiac Diagnostic Tests*, C5) or angiography
- echocardiography
 - to assess systolic murmur suggestive of aortic stenosis (AS), mitral regurgitation (MR) and/or hypertrophic cardiomyopathy (HCM)
 - to assess LV function in patients with Hx of prior MI, pathological Q waves, signs or symptoms of congestive heart failure (CHF)

Chronic stable angina is most often due to a fixed stenosis caused by an atheroma.

Acute coronary syndromes are the result of plaque rupture.

Canadian Cardiovascular Society (CCS) Functional Classification of Angina

- **Class I:** ordinary physical activity (walking, climbing stairs) does not cause angina; angina with strenuous, rapid, or prolonged activity.
- **Class II:** slight limitation of ordinary activity: angina brought on at >2 blocks on level or climbing >1 flight of stairs or by emotional stress.
- **Class III:** marked limitation of ordinary activity: angina brought on at <2 blocks on level or climbing <1 flight of stairs.
- **Class IV:** inability to carry out any physical activity without discomfort; angina may be present at rest.

Differential Diagnosis

- cardiovascular
 - aortic dissection
 - pericarditis
 - myocardial infarction (MI)
- respiratory (e.g. PE, pneumothorax, pneumonia)
- gastrointestinal (e.g. peptic ulcer disease, gastroesophageal reflux disease, esophagitis, gastritis, esophageal spasm, esophageal rupture)
- musculoskeletal (e.g. rib fracture, costochondritis, muscle spasm)
- neurological (e.g. herpes zoster)
- psychiatric (e.g. anxiety)

Optimal Medical Therapy with or without PCI for Stable Coronary Disease. COURAGE Trial
NEJM 2007; 356:1503-16

Study: Randomized, controlled trial with median follow-up of 4.6 years.

Population: 2287 patients who had objective evidence of myocardial ischemia and significant stable coronary artery disease.

Intervention: Patients were randomized to receive intensive pharmacologic therapy and lifestyle intervention with or without percutaneous coronary intervention (PCI).

Outcome: Primary outcome was all-cause mortality and nonfatal myocardial infarction (MI). Secondary outcome had additional events of stroke, all MI, and hospitalization for unstable angina with negative biomarkers.

Results: There was no significant difference in primary (unadjusted hazard ratio: 1.05; $P=0.62$) or secondary outcomes (hazard ratio: 1.05; $P=0.62$) between the PCI and non-PCI intervention groups. The PCI group had significantly lower rates of revascularization at 4.6 years of follow-up (hazard ratio 0.60, $P<0.001$) and was more angina-free in the first 4 years of follow-up.

Conclusions: PCI as an adjunct in initial management in patients with significant stable coronary artery disease does not reduce mortality, MI, stroke or hospitalization for ACS, but does provide angina relief and reduced risk of revascularization.

Treatment of Chronic Stable Angina**1. General measures**

- goals: to reduce myocardial oxygen demand and/or increase oxygen supply
- lifestyle modification
- treatment of risk factors: statins (see [Endocrinology](#), E2, [Family Medicine](#), FM6 for target lipid guidelines), anti-hypertensives, etc.
- exercise program

2. Anti-platelet therapy (first line therapy)

- enteric coated ASA (ECASA)
- clopidogrel when ASA absolutely contraindicated

3. β -blockers (first line therapy – decrease overall mortality)

- increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
- cardioselective agents preferred (e.g. metoprolol, atenolol) to avoid peripheral effects (inhibition of vasodilation and bronchodilation via β_2 receptors)
- avoid intrinsic sympathomimetics (e.g. acebutolol) which increase demand

4. Nitrates (symptomatic control, no clear impact on survival)

- decrease preload (venous dilatation) and afterload (arteriolar dilatation), and increase coronary perfusion
- maintain daily nitrate-free intervals to prevent tolerance (tachyphylaxis)

5. Calcium channel blockers (CCBs, second line or combination)

- increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
- caution: verapamil/diltiazem combined with beta-blockers may cause symptomatic sinus bradycardia or AV block

6. ACE inhibitors (ACEIs, not used to treat symptomatic angina)

- angina patients tend to have risk factors for CV disease which warrant use of an ACEI (e.g. hypertension, diabetes, proteinuric renal disease, previous MI with LV dysfunction)
- class IIa evidence of benefit in all patients at high risk for CV disease
- class I evidence in patients with concomitant DM, renal dysfunction or LV systolic dysfunction
- angiotensin II receptor blockers (ARBs) when ACEIs contraindicated (e.g. hypersensitivity, angioedema)

7. Invasive Strategies

- revascularization (see *Coronary Revascularization* and *COURAGE trial*)

VARIANT ANGINA (Prinzmetal's Angina)

- myocardial ischemia secondary to coronary artery vasospasm, with or without atherosclerosis
- uncommonly associated with infarction or LV dysfunction
- typically occurs between midnight and 8 AM, unrelated to exercise, relieved by nitrates
- typically ST elevation on ECG
- diagnosed by provocative testing with ergot vasoconstrictors (rarely done)
- treat with nitrates and CCBs

SYNDROME X

- typical symptoms of angina but normal angiogram
- may show definite signs of ischemia with exercise testing
- thought to be due to inadequate vasodilator reserve of coronary resistance vessels
- better prognosis than overt epicardial atherosclerosis

Acute Coronary Syndromes (ACS)

Definition

- coronary atherosclerosis with superimposed thrombus on ruptured plaque
- other causes of unstable angina:
 - coronary thromboembolism (e.g. infective endocarditis, intracavity thrombus, paradoxical embolism) or cholesterol embolism
 - severe coronary vasospasm
 - coronary dissection
 - increased demand can also contribute (e.g. tachycardia, anemia)

Spectrum of ACS

- unstable angina (UA)/non-ST elevation myocardial infarction (NSTEMI)
- ST elevation myocardial infarction (STEMI)
- sudden cardiac death

Investigations

- history and physical
 - note that up to 30% of MIs are unrecognized or “silent” due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
- ECG, CXR
- labs
 - serum cardiac biomarkers for myocardial damage (repeat 8 hours later) (see *Cardiac Biomarkers*, C9)
 - CBC, INR/aPTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
 - draw serum lipids within 24-48 hours because values are unreliable from 2 to 48 days post-MI

Is This Patient Having a Myocardial Infarction? JAMA 1998; 280:1256-63

The most compelling features that increase the likelihood of MI are ST-segment elevation, new Q-wave, chest pain radiating to both the right and left arm simultaneously, presence of an S3 and hypotension.

The most compelling features that decrease the likelihood of MI are normal ECG report, pleuritic chest pain, pain reproduced on palpation, sharp or stabbing chest pain, and positional chest pain.

Unstable Angina (UA)/Non ST Elevation MI (NSTEMI)

Definition

- syndrome of acute plaque rupture and thrombosis with incomplete or transient vessel occlusion
- unstable angina** is clinically defined by any of the following:
 - accelerating pattern of pain: increased frequency, increased duration, with decreased exertion, decreased response to treatment
 - angina at rest
 - new onset angina
 - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])
- NSTEMI is clinically defined by the presence of 2 of 3 criteria:
 - symptoms of angina/ischemia
 - rise and fall of serum markers of myocardial necrosis
 - evolution of ischemic ECG changes (without ST elevation or new LBBB)
- acute phase of UA/NSTEMI**
 - risk of progression to MI or the development of recurrent MI or death is highest in the early period
 - at 1 to 3 months after the acute phase, most patients resume a clinical course similar to that in patients with chronic stable coronary disease
- majority of NSTEMIs do not result in the development of Q waves

TIMI Risk Score for UA/NSTEMI

Characteristics	Points
Historical	
Age ≥ 65 yrs	1
≥ 3 risk factors for CAD	1
Known CAD (stenosis $\geq 50\%$)	1
Aspirin use in past 7 days	1
Presentation	
Recent (≤ 24 hr) severe angina	1
ST-segment deviation ≥ 0.5 mm	1
increased cardiac markers	1
Risk Score = Total Points	
If TIMI risk score ≥ 3 , consider early LMWH and angiography	
CAD = coronary artery disease	
NSTEMI = non ST-segment elevation myocardial infarction	
TIMI = thrombolysis in myocardial infarction	
UA = unstable angina	
JAMA 2000; 284:835-842	

ST Elevation Myocardial Infarction (STEMI)

Definition

- syndrome of acute plaque rupture and thrombosis with total coronary occlusion resulting in myocardial necrosis
- STEMI is clinically defined by new ischemic ECG changes plus one or both of ischemic symptoms and elevated cardiac enzymes
 - ECG criteria (see *Approach to ECGs*, C5)
 - ST elevation in 2 contiguous leads (≥ 1 mm in limb leads or ≥ 2 mm in precordial leads) or new BBB (either LBBB or RBBB)

Acute Management of STEMI

- after diagnosis of STEMI is made, do not wait for results of further investigations before implementing reperfusion therapy
- goal is to re-perfuse artery: thrombolysis (EMS-to-needle) within **30 minutes** or primary PCI (EMS-to-balloon) within **90 minutes** (depending on capabilities of hospital)

Treatment of NSTEMI

BEMOAN
 β -blocker
 Enoxaparin

Enoxaparin versus Unfractionated Heparin with Fibrinolysis for ST-elevation Myocardial Infarction

NEJM 2006; 354:1477-88

Study: Prospective, randomized, controlled multicentre trial.

Patients: 20,479 patients (median age 60 yrs. 77% male) with STEMI who were scheduled to undergo fibrinolysis.

Intervention: Patients were randomized to receive either enoxaparin or weight based unfractionated heparin in addition to thrombolysis and standard therapies.

Primary Outcome: Death or recurrent nonfatal MI 30 days post-event.

Results: The composite primary outcome occurred less often in the enoxaparin group compared with those who received unfractionated heparin (9.9% vs. 12.0%, $p < 0.001$, NNT=47). Taken separately, there was a trend toward reduced mortality (6.9% vs. 7.5%, $p = 0.11$) and a significant reduction in nonfatal reinfarction (3.0% vs. 4.5%, $p < 0.001$) in the enoxaparin group. The risk of major bleeding was significantly increased in the enoxaparin group (2.1% vs. 1.4%, $p < 0.001$, NNH=142).

Conclusion: In patients with STEMI receiving thrombolysis, enoxaparin is superior to unfractionated heparin in preventing recurrent nonfatal MI and may lead to a small reduction in mortality.

MANAGEMENT OF ACUTE CORONARY SYNDROMES

1. General measures

- ABCs: assess and correct hemodynamic status first
- bed rest, cardiac monitoring, oxygen
- nitroglycerin SL followed by IV
- morphine IV

2. Anti-platelet and anticoagulation therapy

- ASA 162-325 mg chewed
- **NSTEMI**
 - ♦ clopidogrel 300 mg loading dose, then 75 mg QD in addition to ASA or if ASA contraindicated
 - ♦ subcutaneous Low Molecular Weight Heparin or IV unfractionated heparin (UFH) (LMWH preferable, except in renal failure or if CABG is planned within 24h)
- if PCI is planned: clopidogrel 300 mg loading dose and IV GP IIb/IIIa inhibitor (e.g. abciximab)
- anticoagulation options depend on reperfusion strategy:
 - ♦ primary PCI: UFH during procedure; bivalirudin possible alternative
 - ♦ thrombolysis: LMWH (enoxaparin) until discharge from hospital; can use UFH as alternative because of possible rescue PCI
 - ♦ no re-perfusion: LMWH (enoxaparin) until discharge from hospital
- continue LMWH or UFH followed by oral anticoagulation at discharge if at high risk for thromboembolic event (large anterior MI, AFib, severe LV dysfunction, CHF, previous DVT or PE, or echo evidence of mural thrombus)

3. Beta-blockers

- first dose IV followed by oral administration
- non-dihydropyridine CCB (e.g. diltiazem, verapamil) in absence of severe LV dysfunction in patients with continuing or frequently recurring ischemia when beta-blockers are contraindicated (evidence suggests that CCBs do not prevent MI or decrease mortality)
- **STEMI:** if bradycardia is present, consider administering atropine (increased mortality in patients with hemodynamic compromise with early IV beta-blockers)

4. Invasive strategies and reperfusion options

- **UA/NSTEMI:** early coronary angiography ± revascularization if possible is recommended with any of the following high-risk indicators (class I):
 - ♦ recurrent angina/ischemia at rest despite intensive anti-ischemic therapy
 - ♦ CHF or LV dysfunction
 - ♦ hemodynamic instability
 - ♦ high (≥ 3) TIMI risk score (tool used to estimate mortality following an ACS)
 - ♦ sustained ventricular tachycardia
 - ♦ dynamic ECG changes
 - ♦ high-risk findings on non-invasive stress testing
 - ♦ PCI within the previous 6 months
 - ♦ repeated presentations for ACS despite treatment and without evidence of ongoing ischemia or high risk features (class IIa)
- **note: thrombolysis is NOT administered for UA/NSTEMI**
- **STEMI**
 - ♦ Percutaneous Coronary Intervention (PCI)
 - early PCI (≤ 12 hrs after symptom onset and < 90 mins after presentation) improves mortality vs. thrombolysis with fewer intra-cranial hemorrhages and re-current MIs
 - primary PCI: without prior thrombolytic therapy – method of choice for re-perfusion in experienced centres (JAMA 2004; 291:736-39)
 - rescue PCI: following failed thrombolytic therapy (diagnosed when, following thrombolysis, ST segment elevation fails to resolve below half its initial magnitude and patient still having chest pain)
 - ♦ Thrombolysis
 - preferred if patient presents ≤ 12 hrs of symptom onset, and < 30 min after presentation to hospital, has contraindications to PCI, or PCI cannot be administered within 90 min by a skilled practitioner

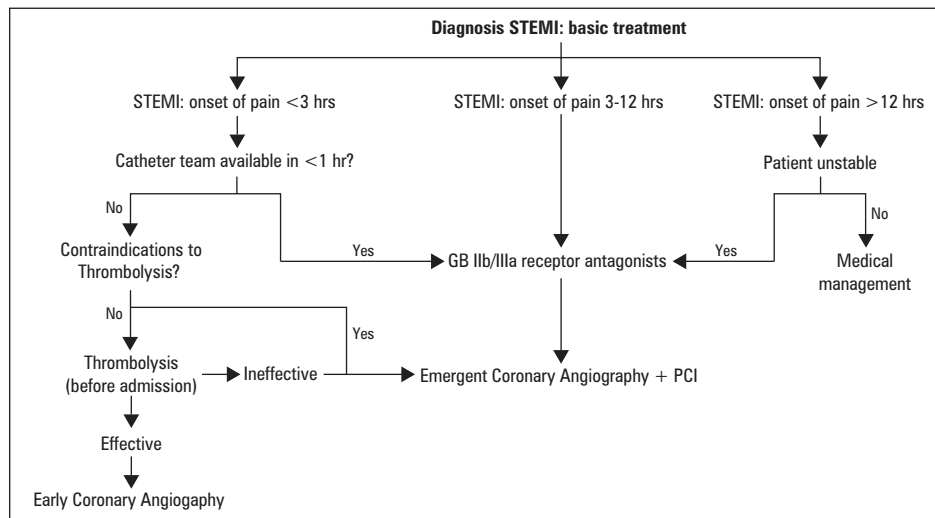

Figure 30. Reperfusion Strategy in STEMI

Table 7. Contraindications and Cautions for Thrombolysis in STEMI

Absolute	Relative
Prior intracranial hemorrhage	Chronic, severe, poorly controlled hypertension
Known structural cerebral vascular lesion	Uncontrolled hypertension (sBP>180, dBP>110)
Known malignant IC neoplasm	Current anticoagulation
Significant closed-head or facial trauma (≤3 months)	Noncompressible vascular punctures
Ischemic stroke (≤3 months)	Ischemic stroke (≥3 months)
Active bleeding	Recent internal bleeding (≤2-4 weeks)
Suspected aortic dissection	Prolonged CPR or major surgery (≤3 weeks)
	Pregnancy
	Active peptic ulcer

Long-Term Management ACS (post-discharge)

- pre-discharge: ECG (if not fully revascularized) and echo
- drugs required in hospital to control ischemia should be continued after discharge in all patients (class IIa) including patients with LV dysfunction, CHF, and diabetics (class I) and all patients who did not undergo revascularization

1. General Measures

- education
- risk factor modification

2. Anti-platelet and Anti-Coagulation Therapy

- ECASA 81-162 mg QD
- clopidogrel 75 mg QD (at least 1 month, up to 9-12 months, if stent placed at least 12 months)
- ± warfarin x 3 months if high risk (large anterior MI, LV thrombus, LVEF <30%, history of VTE, chronic AF)

3. Beta-Blockers (e.g. metoprolol 25-50 mg bid or atenolol 50-100 mg QD)**4. Nitrates**

- alleviate ischemia but do not improve outcome
- use caution in right-sided MI patients who are preload dependent

5. Calcium Channel Blockers (NOT recommended as first line treatment, consider as alternative to beta-blockers)**6. Angiotensin-Converting Enzyme Inhibitors (ACEI)**

- prevent adverse ventricular remodelling
- recommended for asymptomatic patients, even if LVEF >40%
- recommended for symptomatic CHF, reduced LVEF (<40%), anterior MI
- use ARBs in patients who are intolerant of ACEIs

7. ± Aldosterone Antagonists

- if on ACEI and beta-blockers and LVEF <40% and CHF or DM
- significant mortality benefit shown with eplerenone by 30 days

8. Statins (early, intensive, irrespective of cholesterol level; e.g. atorvastatin 80 mg QD)**9. Invasive** (risk stratification, see Figure 31)

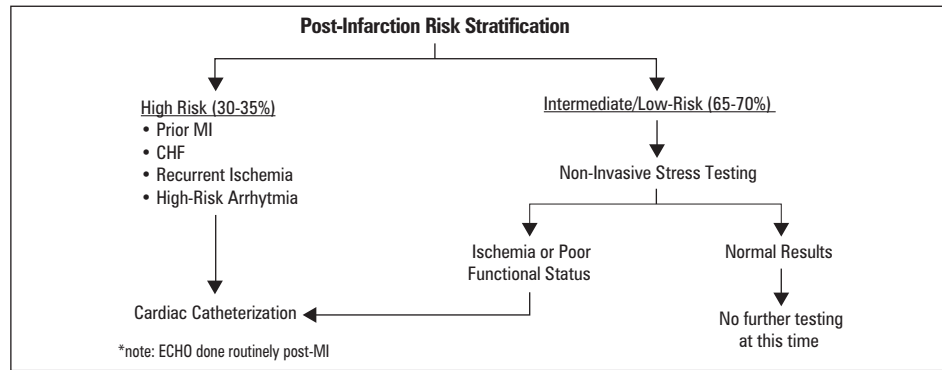

Figure 31. Post-MI Risk Stratification

Resting LVEF is a useful prognostic factor.

Prognosis following STEMI

- 5-15% of hospitalized patients will die
 - risk factors
 - ♦ infarct size/severity
 - ♦ age
 - ♦ co-morbid conditions
 - ♦ development of heart failure or hypotension
- post-discharge mortality rates
 - 6-8% within first year, half of these within first 3 months
 - 4% per year following first year
 - risk factors
 - ♦ LV dysfunction
 - ♦ residual myocardial ischemia
 - ♦ ventricular arrhythmias
 - ♦ history of prior MI

Table 8. Complications of Myocardial Infarction

Complication	Etiology	Presentation	Therapy
Arrhythmia			
1. Tachycardia	Sinus, AF, VT, VFib	First 48 hrs	See <i>Arrhythmias</i> , C12
2. Bradycardia	Sinus, AV block	First 48 hrs	
Myocardial Rupture			
1. LV free wall	Transmural infarction	1-7 days	Surgery
2. Papillary muscle (→ MR)	Inferior infarction	1-7 days	Surgery
3. Ventricular septum (→ VSD)	Septal infarction	1-7 days	Surgery
Shock/CHF	Infarction or aneurysm	Within 48 hours	Inotropes, intra-aortic balloon pump
Post-Infarct Angina	Persistent coronary stenosis multivessel disease	Anytime	Aggressive medical therapy PCI or CABG
Recurrent MI	Reocclusion	Anytime	See above
Thromboembolism	Mural/apical thrombus DVT	7-10 days, up to 6 months	Anticoagulation
Pericarditis	Inflammatory	1-7 days	ASA
(Dressler's syndrome)	Autoimmune	2-8 weeks

Treatment Algorithm for Chest Pain

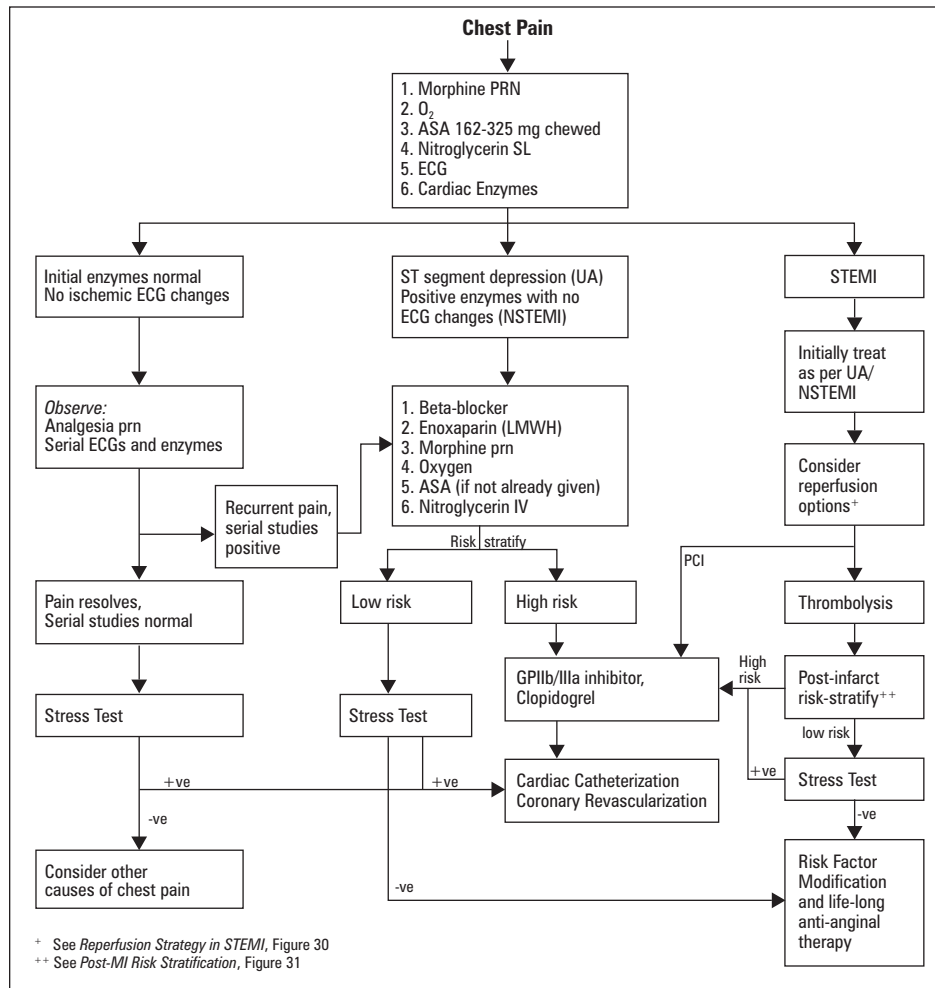

Figure 32. Treatment Algorithm for Chest Pain

Adapted from Cecil Essentials of Medicine 6th Ed. Andreoli and Carpenter. p.101 (2004) with permission from Elsevier

Sudden Cardiac Death

Definition

- unanticipated, non-traumatic cardiac death in stable patient, within 1 hour of symptom onset; ventricular fibrillation is most common cause

Etiology

- primary cardiac pathology
 - ischemia/MI
 - LV dysfunction
 - severe ventricular hypertrophy
 - ♦ hypertrophic cardiomyopathy (HCM)
 - ♦ AS
 - long QT syndrome
 - congenital heart disease

Management

- acute: resuscitate with prompt CPR and defibrillation
- investigate underlying cause (cardiac catheterization, electrophysiologic studies)
- treat underlying cause
- anti-arrhythmic drug therapy: amiodarone, beta-blockers
- implantable cardioverter defibrillator (ICD)

Percutaneous Coronary Intervention (PCI)

Safety and Efficacy of Drug-Eluting and Bare Metal Stents

Circulation 2009; 119:3198-3206

Study: Meta-analysis of RCTs and observational studies. 22 RCTs and 34 observational studies.

Population: 9,470 and 182,901 patients in RCTs and observational studies respectively who underwent percutaneous coronary intervention.

Intervention: Drug-Eluting Stents (DES) versus Bare Metal Stents (BMS).

Outcome: All-cause mortality, myocardial infarction (MI), and target vessel revascularization (TVR).

Results: No difference in mortality was found between DES vs. BMS by RCTs, while observational studies showed significantly lower mortality rates in DES-treated patients (hazard ratio (HR) 0.78, $p < 0.001$). No difference in MI incidence was found in RCTs, while lower incidences of MI were found in observational studies (HR 0.87, $p = 0.014$). DES has a significantly lower TVR rate in both RCT (HR 0.45, $p < 0.001$) and observational studies (HR 0.46, $p < 0.001$).

Conclusions: DES significantly reduces rates of TVR compared to BMS. Although there is no difference in mortality or MI incidence as found by RCTs, observational studies suggest lowered mortality and MI rates in patients with DES over BMS.

- interventional technique aimed at relieving significant coronary stenosis
- main techniques: balloon angioplasty, stenting
- less common techniques: rotational/directional/extraction atherectomy

Indications

- medically refractory angina
- NSTEMI/UA with high TIMI risk score within 90 min of presentation
- primary/rescue PCI for STEMI

Balloon Angioplasty and Intracoronary Stenting

- coronary lesions dilated with balloon inflation
- major complication is restenosis, felt to be due to elastic recoil and neointimal hyperplasia
- majority of patients receive intracoronary stent(s) to prevent restenosis
 - bare metal stent (BMS)
 - ♦ coated with antiproliferative drugs (sirolimus, paclitaxel)
 - ♦ reduced rate of neointimal hyperplasia and restenosis compared to BMS (5% vs. 20%)
 - ♦ complication: late stent thrombosis (5 events in 1000 stents implanted)

Adjunctive Therapies

- ASA and heparin decrease post-procedural complications
- further reduction in ischemic complications has now been demonstrated using GPIIb/IIIa inhibitors (abciximab, eptifibatide, tirofiban) in coronary angiography and stenting
- following stent implantation
 - dual antiplatelet therapy (ASA and clopidogrel) for 1 month with BMS or ≥ 12 months with DES

Procedural Complications

- mortality and emergency bypass rates $< 1\%$
- nonfatal MI: approximately 2-3%

Table 9. Choice of Revascularization Procedure

	PCI	CABG
Advantages	<ul style="list-style-type: none"> • Less invasive technique • Less periprocedural morbidity and mortality • Shorter periprocedural hospitalization 	<ul style="list-style-type: none"> • Greater ability to achieve complete revascularization • Less need for repeated revascularization procedures
Indications	<ul style="list-style-type: none"> • Single or double-vessel disease • Inability to tolerate surgery 	<ul style="list-style-type: none"> • Triple-vessel or left main disease • Diabetes mellitus • Plaque morphology unfavourable for PCI

Coronary Artery Bypass Graft (CABG) Surgery

- the objective of CABG is complete reperfusion of the myocardium; goals include relieving symptoms (angina, heart failure) and thus improving quality of life, and/or prolonging life

Indications

- Class I recommendations
 - CABG
 - ♦ significant left main artery disease
 - ♦ triple vessel disease, survival benefit greatest in patients with abnormal LV function (EF $< 50\%$)
 - ♦ two-vessel disease with significant proximal left anterior descending (LAD) disease and with abnormal LV function (EF $< 50\%$) or demonstrable ischemia on noninvasive testing
 - ♦ one or two vessel disease without significant LAD disease who have survived sudden cardiac death or sustained VT
 - CABG or PCI
 - ♦ patients with one or two vessel disease without significant LAD disease but with a large area of viable myocardium and high risk criteria on noninvasive testing
 - ♦ recurrent stenosis associated with a large area of viable myocardium or high risk criteria on noninvasive testing
- Class II recommendations
 - CABG or PCI
 - ♦ one vessel disease with significant proximal LAD
 - ♦ repeat CABG for multiple saphenous vein graft stenosis, with high risk criteria on noninvasive testing, especially when LAD graft at risk. PCI may be appropriate for focal lesions, or multiple lesions in poor surgical candidates
 - ♦ one or two vessel disease without significant proximal LAD disease but with a moderate area of viable ischemia on noninvasive testing

Percutaneous Coronary Intervention versus Coronary-Artery Bypass Grafting for Severe Coronary Artery Disease. SYNTAX trial

NEJM 2009; 360(10):961-972

Study: Prospective, randomized controlled trial.

Population: 1800 patients with untreated three-vessel or left main coronary artery disease and anatomically equivalent for both Percutaneous Intervention (PCI) and Coronary Artery Bypass Graft (CABG).

Intervention: PCI versus CABG.

Outcome: Composite of death from any cause, stroke, myocardial infarction, or repeat revascularization in 12 months post-intervention.

Results: Incidence of primary outcome was lower in the CABG intervention vs. PCI (12.4% vs. 17.8%, $P = 0.002$, NNT = 19). PCI was associated with significantly higher rates of repeat revascularization (13.5% vs. 5.9%, $P < 0.001$) and cardiac death (3.7% vs. 2.1%, $P = 0.05$), while CABG had higher rates of stroke (2.2% vs. 0.6%, $P = 0.03$).

Conclusions: In patients with three-vessel or left main coronary artery disease, CABG is superior to PCI in preventing major adverse cardiovascular and cerebrovascular events within 12 months of intervention.

Operative Issues

- isolated proximal disease in large coronary arteries (>1.0-1.5 mm) is ideal for bypass surgery; small, diffusely diseased coronary arteries are not suitable for bypass surgery
- arteries with severe stenoses (>50% diameter reduction) are bypassed, except those of small calibre (<1 mm in diameter)

Table 10. Risk Factors for CABG Mortality and Morbidity

Risk Factors for CABG Mortality (decreasing order of significance)	Risk Factors for CABG Postop Morbidity or Length of Stay (decreasing order of significance)
<ul style="list-style-type: none"> Urgency of surgery (emergent or urgent) Reoperation Older age Poor left ventricular function (see below) Female gender Left main disease Others include catastrophic conditions (cardiogenic shock, ventricular septal rupture, ongoing CPR), dialysis-dependent renal failure, end-stage COPD, diabetes, cerebrovascular disease, and peripheral vascular disease 	<ul style="list-style-type: none"> Reoperation Emergent procedure Preoperative intra-aortic balloon pump (IABP) Congestive heart failure CABG + valve surgery Older age Renal dysfunction COPD Diabetes Cerebrovascular disease

- left ventricular (LV) function is an important determinant of outcome of all heart diseases
- patients with severe LV dysfunction usually have poor prognosis, but surgery can sometimes dramatically improve LV function
- assess viability of non-functioning myocardial segments using delayed thallium myocardial imaging, PET scanning or MRI

Table 11. Conduits for CABG

Graft	Occlusion/Patency Rate	Considerations
Saphenous Vein Grafts (SVG)	At 10 years, 50% occluded, 25% stenotic, 25% angiographically normal	<ul style="list-style-type: none"> Used when arterial grafts are not available or many grafts are required, such as triple or quadruple bypass
Left Internal Thoracic/Mammary Artery (LITA/LIMA) (LIMA to LAD)	90-95% patency at 15 years	<ul style="list-style-type: none"> Most preferred option because of excellent patency Improved event-free survival (angina, MI) Decreased late cardiac events No increase in operative risk
Right Internal Thoracic/Mammary Artery (RITA/RIMA)	Pedicled RIMA patency comparable to LIMA free RIMA patency less	<ul style="list-style-type: none"> Used in bilateral ITA grafting Patients receiving bilateral ITAs have less risk of recurrent angina, late myocardial infarction, angioplasty
Radial Artery (free graft)	85-90% patency at 5 years	<ul style="list-style-type: none"> Prone to severe vasospasm postoperatively due to muscular wall
Right Gastroepiploic Artery	80-90% patency at 5 years	<ul style="list-style-type: none"> Primarily used as an in situ graft to bypass the RCA Use limited because of the fragile quality of the artery, other technical issues, increased operative time (laparotomy incision) and incisional discomfort with associated ileus
Complete Arterial Revascularization		<ul style="list-style-type: none"> For younger patients (<60 years of age) Is preferred due to longer term graft patency
Redo Bypass Grafting		<ul style="list-style-type: none"> Operative mortality 2-3 times higher than first operation 10% perioperative MI rate Reoperation undertaken only in symptomatic patients who have failed medical therapy and in whom angiography has documented progression of the disease Increased risk with redo-sternotomy secondary to adhesions which may result in laceration to aorta, RV, IMA and other bypass grafts

Off-Pump Coronary Artery Bypass (OPCAB) Surgery

- complications of CABG with cardiopulmonary bypass (CPB)
 - stroke and neurocognitive defects (microembolization of gaseous and particulate matter)
 - immunosuppression
 - systemic inflammatory response leading to:
 - myocardial dysfunction
 - renal dysfunction
 - neurological injury
 - respiratory dysfunction
 - coagulopathies

Procedure

- OPCAB avoids the use of CPB by allowing surgeons to operate on a beating heart
 - stabilization devices (e.g. Genzyme Immobilizer®) hold heart in place allowing operation while positioning devices (Medtronic Octopus® and Starfish® system) allow the surgeon to lift the beating heart to access the lateral and posterior vessels
 - procedure is safe and well tolerated by most patients; however, OPCAB surgery remains technically more demanding

Indications

- used in poor candidates for CPB who have: calcified aorta, poor LVEF, severe peripheral vascular disease (PVD), severe COPD, CRF, coagulopathy, transfusion issues (e.g. Jehovah's Witness), good target vessels, anterior/lateral wall revascularization, target revascularization in older, sicker patients
- **absolute contraindications:** hemodynamic instability, poor quality target vessels including intramyocardial vessels, diffusely diseased vessels and calcified coronary vessels
- **relative contraindications:** cardiomegaly/CHF, critical left main disease, small distal targets, recent or current acute MI, cardiogenic shock, LVEF <35%

Outcomes

- OPCAB decreases in-hospital morbidity (decreased incidence of chest infection, inotropic requirement, supraventricular arrhythmia), blood product transfusion, ICU stay, length of hospitalization, and decreased CK-MB and troponin I level
- no significant difference in terms of survival at 2 years, frequency of cardiac events (MI, PCI, CHF, recurrent angina, redo CABG) or medication usage compared to on-pump CABG

Heart Failure

Congestive Heart Failure (CHF)

Definitions

- heart failure: a complex clinical syndrome, resulting from almost any cardiac disorder that impairs the ability of the ventricle to fill with or eject blood
- forward heart failure: heart unable to maintain adequate cardiac output to meet demand and/or able to do so only by elevating filling pressure
- backward heart failure: heart unable to accommodate venous return resulting in elevated filling pressures and vascular congestion (systemic or pulmonary)
- heart failure can involve left side of heart (left heart failure), right side (right heart failure) or both (biventricular failure) (see Table 12)
- heart failure can also have components of ineffective ventricular filling (diastolic dysfunction) and/or contraction (systolic dysfunction)
- most cases associated with poor cardiac output (low-output heart failure); however, some not due to intrinsic cardiac disease but instead due to increased demand (high-output heart failure)

Pathophysiology

- primary insults (myocyte loss, overload) → pump dysfunction, which leads to:
 - remodeling (dilatation, hypertrophy)
 - neurohumoral activation → necrosis and apoptosis
- both pathways result in further damage (re-starting the cycle), edema, tachycardia, vasoconstriction, congestion
- compensatory response to myocardial stress (perpetuate disease process)
 - increased end-systolic ventricular pressure (pressure overload)
 - ♦ e.g. HTN, aortic stenosis → hypertrophy
 - increased end-diastolic ventricular volume (volume overload)
 - ♦ e.g. aortic regurgitation → cardiac dilatation
- systemic response to ineffective circulating volume
 - activation of sympathetic nervous and renin-angiotensin-aldosterone systems results in:
 - ♦ salt and water retention with intravascular expansion
 - ♦ increased heart rate and myocardial contractility
 - ♦ increased afterload

Systolic Dysfunction (impaired ventricular ejection)

- impaired myocardial contractile function → decreased ejection fraction (LVEF) and stroke volume (SV) → decreased cardiac output (CO)
- findings: apex beat displaced, S3, increased heart size on CXR, decreased LVEF, LV dilatation
- causes:
 - ischemic (e.g. extensive CAD, previous MI)
 - non-ischemic
 - ♦ hypertension
 - ♦ diabetes mellitus
 - ♦ alcohol (and other toxins)
 - ♦ myocarditis
 - ♦ dilated cardiomyopathy

Dichotomies of Heart Failure
 Forward vs. Backward
 Left-sided vs. Right-sided
 Systolic dysfunction vs. Diastolic dysfunction
 Low output vs. High output

Use Ejection Fraction to Grade LV Dysfunction
 Grade I (EF > 60%) (Normal)
 Grade II (EF = 40-59%)
 Grade III (EF = 21-39%)
 Grade IV (EF ≤ 20%)

Diastolic Dysfunction (impaired ventricular filling)

- at least 1/3 of all HF patients have normal systolic function (i.e. normal ejection fraction); prevalence higher in older patients
- increased LV filling pressures produce venous congestion upstream (i.e. pulmonary and systemic venous congestion)
- findings: HTN, apex beat sustained, S4, normal-sized heart on CXR, LVH on ECG/echo, normal LVEF
- causes of decreased compliance:
 - transient: ischemia (relaxation of myocardium is active and requires ATP)
 - permanent
 - ♦ severe hypertrophy (HTN, AS, HCM)
 - ♦ restrictive cardiomyopathy (RCM)
 - ♦ MI

High-Output Heart Failure

- caused by demand for increased cardiac output
- often exacerbates existing heart failure or decompensates a patient with other cardiac pathology
- differential diagnosis: anemia, thiamine deficiency (beriberi), hyperthyroidism, A-V fistula or L-R shunting, Paget's disease, renal disease, hepatic disease

Etiologies of Primary Insults

- consider predisposing, precipitating and perpetuating factors
- most common causes see sidebar
- less common causes of CHF
 - toxic e.g. anthracyclines, radiation, uremia, catecholamines
 - infectious e.g. Chagas' disease (common cause in South America), Coxsackie virus, HIV
 - endocrine e.g. hyperthyroidism, DM, acromegaly
 - infiltrative e.g. sarcoidosis, amyloidosis, hemochromatosis
 - genetic e.g. HCM, Friedreich's Ataxia, muscular dystrophy
 - congenital heart disease
 - metabolic e.g. thiamine deficiency, selenium deficiency
 - peripartum

Precipitants of Symptomatic Exacerbations

- consider natural progression of disease vs. new precipitant
- always search for reversible cause
- see side bar ("HEART FAILED")
- differential can also be organized as follows:
 - new cardiac insult/disease: MI, arrhythmia, valvular disease
 - new demand on CV system: hypertension, anemia, thyrotoxicosis, infection, etc.
 - failure to take medications as prescribed

Table 12. Signs and Symptoms of Left vs. Right Heart Failure

	Left Failure	Right Failure
Low cardiac output (forward)	Fatigue Syncope Systemic hypotension Cool extremities Slow capillary refill Peripheral cyanosis Pulsus alternans Mitral regurgitation S3	Right heart failure can mimic most of the symptoms of forward left heart failure if decreased RV output leads to LV underfilling
Venous congestion (backward)	Dyspnea, orthopnea, PND Cough Crackles	Tricuspid regurgitation S3 (right-sided) Peripheral edema Elevated JVP with AJR and Kussmaul's sign Hepatomegaly Pulsatile liver

Investigations

- identify and assess precipitating factors and treatable causes of CHF
- blood work: CBC, electrolytes (including calcium and magnesium), BUN, creatinine, fasting blood glucose, HbA1C, lipid profile, liver function tests, serum thyroid-stimulating hormone, \pm ferritin, BNP, uric acid (associated with prognosis of HF in Seattle HF Score)
- ECG: look for chamber enlargement, arrhythmia, ischemia/infarction
- CXR: cardiomegaly, pleural effusion, redistribution, Kerley B-lines, bronchiolar-alveolar cuffing
- echocardiography: LVEF, cardiac dimensions, wall motion abnormalities, valvular disease, pericardial effusion
- radionuclide angiography (MUGA): LVEF
- myocardial perfusion scintigraphy (thallium or sestamibi SPECT)

**New York Heart Association (NYHA) Functional Classification of Heart Failure**

- **Class I:** ordinary physical activity does not cause symptoms of HF
- **Class II:** comfortable at rest, ordinary physical activity results in symptoms
- **Class III:** marked limitation of ordinary activity; less than ordinary physical activity results in symptoms
- **Class IV:** inability to carry out any physical activity without discomfort; symptoms may be present at rest

**What are the Five Most Common Causes of CHF?**

1. Coronary artery disease (60-70%)
2. HTN
3. Idiopathic (often in the form of dilated cardiomyopathy)
4. Valvular (e.g. AS, AR and MR)
5. Alcohol (may cause dilated cardiomyopathy)

**Precipitants of Heart Failure****HEART FAILED**

- Hypertension (common)
- Endocarditis/environment (e.g. heart wave)
- Anemia
- Rheumatic heart disease and other valvular disease
- Thyrotoxicosis
- Failure to take meds (very common)
- Arrhythmia (common)
- Infection/ischemia/Infarction (common)
- Lung problems (PE, pneumonia, COPD)
- Endocrine (pheochromocytoma, hyperaldosteronism)
- Dietary indiscretions (common)

The most common cause of right heart failure is left heart failure.

**Measuring NT-pro BNP**

BNP is secreted by ventricles due to LV stretch and wall tension. Cardiomyocytes secrete BNP precursor that is cleaved into proBNP. After secretion into ventricles, proBNP is cleaved into the active C-terminal portion and the inactive NT-proBNP portion.

NT-proBNP levels (pg/mL)

Age	HF very likely
<50	>450
50-75	>900
>75	>1800

Limitations – Age, body habitus, renal function, pulmonary embolism

Features of Heart Failure on CXR

HERB-B

Heat enlargement (cardiothoracic ratio >0.50)

Effusion

Re-distribution (alveolar edema)

B-lines

Bronchiolar-alveolar cuffing

Acute Treatment of Pulmonary Edema

- treat acute precipitating factors (e.g. ischemia, arrhythmias)
- **L** – Lasix® (furosemide) 40-500 mg IV
- **M** – morphine 2-4 mg IV – decreases anxiety and preload (venodilation)
- **N** – nitroglycerin – topical/IV/SL
- **O** – oxygen
- **P** – positive airway pressure (CPAP/BiPAP) – decreases preload and need for ventilation
- **P** – position – sit patient up with legs hanging down unless patient is hypotensive
- in ICU setting or failure of LMNOP, other interventions may be necessary
 - nitroprusside (IV)
 - hydralazine (PO)
 - sympathomimetics
 - ♦ dopamine
 - low dose: selective renal vasodilation (high potency D_1 agonist)
 - medium dose: inotropic support (medium potency β_1 agonist)
 - high dose: increases SVR (low potency β_1 agonist), which is undesirable
 - ♦ dobutamine
 - selective inotrope (β_1 agonist) and arterial vasodilator (β_1 antagonist)
 - ♦ phosphodiesterase inhibitors (milrinone)
 - inotropic effect and vascular smooth muscle relaxation (decreased SVR), similar to dobutamine
 - adverse effect on survival when used as long-term oral agent
- consider PA catheter to monitor pulmonary capillary wedge pressure (PCWP) if patient is unstable or a cardiac etiology is uncertain (PCWP >18 indicates likely cardiac etiology)
- mechanical ventilation as needed
- rarely used, but potentially life-saving measures:
 - intra-aortic balloon pump (IABP)
 - left or right ventricular assist device (LVAD/RVAD)
 - cardiac transplant

Long Term Management

Conservative Measures

1. Symptomatic measures: oxygen in hospital, bedrest, elevation of head of bed
2. Lifestyle measures (grade B evidence): diet, exercise, DM control, smoking cessation, decrease alcohol consumption, patient education, sodium and fluid restriction
3. Multidisciplinary heart failure clinics (grade B evidence): for management of individuals at higher risk, or with recent hospitalization

Pharmacological Therapy

1. Vasodilators

- a. ACEIs: standard of care – slow progression of LV dysfunction and improve survival
 - ♦ all symptomatic patients functional class II-IV (grade A)
 - ♦ all asymptomatic patients with LVEF <40% (grade A)
 - ♦ post-MI
 - ♦ target dose as used in mortality trials, or maximum tolerated dose
- b. angiotensin II receptor blockers (ARBs)
 - ♦ second line to ACEI if not tolerated (grade B), or as adjunct to ACEI if beta-blockers not tolerated (grade A)
- c. hydralazine and nitrates (Ve-HeFT-I trial)
 - ♦ second line to ACEI, decrease in mortality not as great as with ACEI
 - ♦ may consider in acute renal failure until creatinine stabilizes

2. Beta-blockers: slow progression and improve survival

- class I-III with LVEF <40% (grade A)
- stable class IV patients (grade A)
- **note: should be used cautiously, titrate slowly because may initially worsen CHF**

3. Diuretics: symptom control, management of fluid overload

- furosemide (40-500 mg OD) for potent diuresis
- metolazone may be used with furosemide to increase diuresis
- furosemide, metolazone, and thiazides oppose the hyperkalemia induced by beta-blockers, ACEIs, ARBs, and aldosterone antagonists

4. Aldosterone antagonists: mortality benefit in severe CHF

- spironolactone for class IIIb and IV CHF already on ACEI and loop diuretic (grade A)
- eplerenone may be considered if intolerable endocrine side effects
- **note: potential for life threatening hyperkalemia**
 - ♦ monitor K after initiation and avoid if Cr >220 $\mu\text{mol/L}$ or K >5.2 mmol/L

Can the Clinical Examination Diagnose Left-Sided Heart Failure in Adults?

JAMA 1997; 277:1712-99

"The best findings for detecting increased filling pressure are jugular venous distention and radiographic redistribution."

"The best findings for detecting systolic dysfunction are an abnormal apical impulse, radiographic cardiomegaly, Q-waves or LBBB on an electrocardiogram."

"Diastolic dysfunction is difficult to diagnose but is associated with elevated blood pressure during heart failure."

Chronic Treatment of CHF

- ACE inhibitors*
- Beta blockers*
- \pm Aldosterone antagonists* (if severe CHF)
- Diuretic
- \pm Inotrope
- \pm Antiarrhythmic
- \pm Anticoagulant

* = Mortality Benefit

Medications Contraindicated in CHF

- NSAIDs – may increase BP
- Class I/III antiarrhythmics
- Metformin – C/I in severe HF
- Thiazolidinediones – increase edema
- cGMP phosphodiesterase inhibitors (e.g. sildenafil) with baseline low BP

5. **Inotropes:** digoxin improves symptoms and decreases hospitalizations, no effect on mortality
 - indications: patient in sinus rhythm and symptomatic on ACEI (grade A), or CHF and atrial fibrillation (grade B)
 - patients on digitalis glycosides may worsen if these are withdrawn
6. **Anti-arrhythmic drugs:** for use in CHF with arrhythmia
 - can use amiodarone, beta-blocker, or digoxin (grade B)
7. **Anticoagulants:** warfarin for prevention of thromboembolic events
 - prior thromboembolic event or atrial fibrillation (grade B), presence of LV thrombus on echo
 - possible benefit in other patients with LVEF <30% (controversial)
8. **CCBs** (equivocal effect on survival): not currently recommended

Procedural Interventions

- resynchronization therapy: symptomatic improvement with biventricular pacemaker
 - consider if QRS >130 ms, LVEF <35%, and severe symptoms despite optimal therapy (grade B)
 - greatest benefit likely with marked LV enlargement, MR, QRS >150 ms, high diuretic requirement
- ICD: mortality benefit in 1° and 2° prevention of sudden cardiac death
 - prior MI, optimal medical therapy, LVEF <30%, clinically stable (grade B)
 - prior MI, NSVT, LVEF 30-40%, EPS inducible VT (grade B)
- LVAD/RVAD (see *Ventricular Assist Devices*, C36)
- cardiac transplantation (see *Cardiac Transplantation*, C35)
- valve repair if patient is surgical candidate and has significant valve disease contributing to CHF (see *Valvular Heart Disease*, C40)

Sleep-Disordered Breathing

- 45-55% of patients with CHF have sleep disturbances, including Cheyne-Stokes breathing and sleep apnea (central or obstructive)
- associated with a worse prognosis and greater LV dysfunction
- nasal continuous positive airway pressure (CPAP) is effective in treating Cheyne-Stokes respiration/sleep apnea with improvement in cardiac function and symptoms

Cardiac Transplantation

- for end-stage heart disease; due to ischemic cardiomyopathy (60%), idiopathic cardiomyopathy (20%), and minority due to valvular or congenital problems
- worldwide 1-year survival is 79%, 5-year survival about 60%, annual mortality rate of 4%
- donor hearts are considered from patients up to age 50-55
- matching is according to blood type, body size and weight (should be within 25%), and HLA tissue matching (if time allows)

Indications for Surgery

- severe cardiac disability despite maximal medical therapy (recurrent hospitalizations for CHF, NYHA III or IV, peak metabolic oxygen consumption <14 ml/kg/min in absence of beta-blocker)
- symptomatic cardiac ischemia refractory to conventional treatment (unstable angina not amenable to CABG or angioplasty with LVEF <30%; recurrent, symptomatic ventricular arrhythmias)
- exclusion of all surgical alternatives to cardiac transplantation (revascularization for significant reversible ischemia, valve replacement for critical aortic valve disease, valve replacement or repair for severe MR)

Prerequisites

- emotionally stable with social support
- medically compliant and motivated
- contraindications: incurable malignancy, major systemic illness, irreversible major organ disease (e.g. renal, hepatic), active systemic infection (e.g. Hep C, HIV), obesity, irreversible pulmonary hypertension (pulmonary vascular resistance [PVR] >6 Wood units), severe COPD (FEV₁ <1 L), or active drug addiction or alcoholism
- typically age <70 years

Complications

- rejection
 - common, however less than 5% have serious hemodynamic compromise
 - gold standard to detect rejection: endomyocardial biopsy
 - ◆ no noninvasive tests to detect rejection
 - risk of acute rejection is greatest during the first 3 months after transplant

- infection
 - leading cause of morbidity and mortality after cardiac transplantation
 - risk peaks early during the first few months after transplantation and then declines to a low persistent rate
- allograft coronary artery disease
 - approximately 50% develop graft CAD within 5 years of transplantation
 - the most common cause of late death following transplantation
- malignancy
 - develop in 15% of cardiac transplant recipients
 - second most common cause of late death following transplantation
 - cutaneous neoplasms most common, followed by non-Hodgkin's lymphoma and lung cancer
- immunosuppressive medication side effects (prednisone, cyclosporine, tacrolimus, sirolimus)

Prognosis

- the Heart Failure Survival Score (HFSS) uses 7 prognostic variables – ischemic cardiomyopathy, resting heart rate, LVEF, mean BP, QRS >120ms, serum Na, peak VO_2 – to stratify patients into low, medium, and high risk categories; one-year survival rates without transplant for these three strata were 88, 60, and 35%, respectively

Ventricular Assist Devices (VADs)

- works to unload the ventricle while maintaining its output; also results in decreased myocardial oxygen consumption, permitting recovery of the myocardium that is not irreversibly injured
- can support the left (LVAD), right (RVAD) or both ventricles (BiVAD)
- indications
 - bridge to transplantation
 - postoperative mechanical support when unable to separate from cardiopulmonary bypass despite inotropic and Intra-Aortic Balloon Pump (IABP) support
 - ♦ IABP is a catheter based device inserted into the aorta via the femoral artery that decreases myocardial O_2 demand and increases blood flow to coronary arteries
 - postoperative cardiogenic shock

REMATCH Trial

Ann Thorac Surg 1999; 67:723-730
Increased survival of 23% vs. 8% with LVAD vs. medical management of heart failure after 2 years. Heartmate VAD has a biologic surface, therefore does not require long-term anticoagulation, but higher risk of infection.

Myocardial Disease

Definition of Cardiomyopathy (CMP)

- intrinsic or primary myocardial disease not 2° to congenital, hypertensive, coronary, valvular, or pericardial disease
- functional classification: dilated, hypertrophic or restrictive
- LV dysfunction 2° to MI often termed “ischemic cardiomyopathy”, but is not a true cardiomyopathy (i.e. primary myocardial disorder) since the primary pathology is CAD

Myocarditis

Definition

- inflammatory process involving the myocardium ranging from acute to chronic; an important cause of dilated cardiomyopathy

Etiology

- idiopathic
- infectious
 - viral (most common): coxsackie B, echovirus, poliovirus, HIV, mumps
 - bacterial: *S. aureus*, *C. perfringens*, *C. diphtheriae*, *Mycoplasma*, *Rickettsia*
 - fungi
 - spirochetal (Lyme disease – *Borrelia burgdorferi*)
 - Chagas disease (*Trypanosoma cruzi*), toxoplasmosis
- toxic: catecholamines, chemotherapy, cocaine
- hypersensitivity, eosinophilic: drugs (antibiotics, diuretics, lithium, clozapine), insect/snake bites
- systemic diseases: collagen vascular diseases (SLE, RA, others), sarcoidosis, autoimmune
- other: giant cell myocarditis, acute rheumatic fever

Signs and Symptoms

- constitutional symptoms
- acute CHF
- chest pain – due to pericarditis or cardiac ischemia
- arrhythmias
- systemic or pulmonary emboli
- sudden death

Investigations

- ECG: non-specific ST-T changes \pm conduction defects
- bloodwork
 - increased CK, troponin, LDH, and AST with acute myocardial necrosis \pm increased WBC, ESR, ANA, rheumatoid factor, complement levels
 - blood culture, viral titres and cold agglutinins for Mycoplasma
- CXR: enlarged cardiac silhouette
- echo: dilated, hypokinetic chambers, segmental wall motion abnormalities
- myocardial biopsy

Management

- supportive care
- restrict physical activity
- treat CHF
- treat arrhythmias
- anticoagulation
- treat underlying cause if possible

Prognosis

- usually self-limited and often unrecognized, many recover
- sudden death in young adults
- may progress to dilated cardiomyopathy
- few may have chronic myocarditis

Table 13. Summary Table for CHF and Myocardial Disease

SYSTOLIC HEART FAILURE			DILATOLIC HEART FAILURE	
Dilated Cardiomyopathy	Secondary Causes	Hypertrophic Cardiomyopathy	Restrictive Cardiomyopathy	Secondary Causes
Idiopathic, infectious (e.g. myocarditis), alcohol, familial, collagen vascular disease, etc.	Coronary artery disease, MI, diabetes, valvular (e.g. AR, MR)	Genetic disorder affecting cardiac sarcomeres (most common cause of sudden cardiac death in young athletes)	Amyloidosis, sarcoidosis, scleroderma, hemochromatosis, Fabry's, Pompe's Disease, Loeffler's, etc.	Hypertension, diabetes, valvular (e.g. AS), post-MI, transiently by ischemia, etc.

Dilated Cardiomyopathy (DCM)**Definition**

- unexplained dilation and impaired systolic function of one or both ventricles

Etiology

- idiopathic (presumed viral or genetic) ~50% of DCM
- alcohol
- familial
- uncontrolled tachycardia (e.g. persistent atrial fibrillation)
- collagen vascular disease: SLE, PAN, dermatomyositis, progressive systemic sclerosis
- infectious: viral (coxsackie B, HIV), Chagas disease, Lyme disease, Rickettsial diseases, acute rheumatic fever, toxoplasmosis
- neuromuscular disease: Duchenne muscular dystrophy, myotonic dystrophy, Friedreich's ataxia
- metabolic: uremia, nutritional deficiency (thiamine, selenium, carnitine)
- endocrine: hyper/hypothyroidism, DM, pheochromocytoma
- peripartum
- toxic: cocaine, heroin, organic solvents
- drugs: chemotherapies (doxorubicin, cyclophosphamide), anti-retrovirals, chloroquine, clozapine, TCA
- radiation induced

Signs and Symptoms

- may present as
 - CHF
 - systemic or pulmonary emboli
 - arrhythmias
 - sudden death (major cause of mortality due to fatal arrhythmia)

Major Risks Factors for DCM
Alcohol, cocaine, family history and obesity.

**Abnormal Labs in DCM**

High BNP
High Cr
High LFTs
Low Bicarb
Low Na

Investigations

- bloodwork: CBC, electrolytes, Cr, bicarbonate, BNP, CK, troponin, LFTs, TSH, TIBC
- ECG: variable ST-T wave abnormalities, poor R wave progression, conduction defects (e.g. BBB), arrhythmias (non-sustained VT)
- CXR: global cardiomegaly (globular heart), signs of CHF, pleural effusion
- echocardiography: chamber enlargement, global hypokinesis, depressed LVEF, MR and TR, mural thrombi
- endomyocardial biopsy: not routine, used to rule out a treatable cause
- angiography: in selected patients to exclude ischemic heart disease

Management

- treat underlying disease: e.g. abstinence from EtOH
- treat CHF: see *Heart Failure*, C32
- thromboembolism prophylaxis: anticoagulation with warfarin
 - indicated for: AF, history of thromboembolism or documented thrombus
 - LVEF <30% (controversial)
- treat symptomatic or serious arrhythmias
- immunize against influenza and *S. pneumoniae*
- consider surgical options (e.g. LVAD, transplant, volume reduction surgery) in appropriate candidates with severe, refractory disease
- consider ICD among patients with a LVEF <30%

Prognosis

- depends on etiology
 - better with reversible underlying cause, worst with infiltrative diseases, HIV, drug-induced
- cause of death usually CHF (due to pump failure) or sudden death 2° to ventricular arrhythmias
- systemic emboli are significant source of morbidity
- 20% mortality in 1st year, 10% per year after

Hypertrophic Cardiomyopathy (HCM)

Definition

- defined as unexplained ventricular hypertrophy (not due to systemic HTN or AS)
 - most causes involve asymmetric pattern of hypertrophy (septal hypertrophy most common)

Etiology and Pathophysiology

- histopathologic features include myocyte disarray, myocyte hypertrophy, and interstitial fibrosis
- cause is felt to be a genetic defect involving one of the cardiac sarcomeric proteins (>200 mutations associated with autosomal dominant inheritance, incomplete penetrance)
- prevalence of 1/500-1/1000 in general population
- presents as early as 20-40 yrs old

Hemodynamic Classification

- hypertrophic obstructive cardiomyopathy (HOCM): dynamic LV outflow tract (LVOT) obstruction, either at rest or with provocation
- non-obstructive hypertrophic cardiomyopathy: no LVOT obstruction
- many patients have diastolic dysfunction (impaired ventricular filling secondary to LV hypertrophy which decreases compliance)

Signs and Symptoms (of HCM)

- clinical manifestations: asymptomatic (common, therefore screening is important), SOB, angina, presyncope/syncope (due to LV outflow obstruction or arrhythmia), CHF, arrhythmias, sudden cardiac death (SCD)
- pulses: rapid upstroke, bifid carotid pulse (in HOCM)
- precordial palpation: PMI localized, sustained, double impulse, 'triple ripple' (triple apical impulse in HOCM), LV lift
- precordial auscultation: normal or paradoxically split S2, S4, harsh systolic diamond-shaped murmur at LLSB or apex, enhanced by squat to standing or Valsalva (murmur secondary to LVOT obstruction as compared to aortic stenosis); often with pansystolic murmur due to mitral regurgitation

Investigations

- ECG: LVH, high voltages across precordium, prominent Q waves (lead I, aVL, V5, V6), tall R wave in V1, P wave abnormalities
- echo: asymmetric septal hypertrophy (less commonly apical), systolic anterior motion of mitral valve and MR
- cardiac catheterization (usually performed only when patient being considered for invasive therapy)

Management

- avoid factors which increase obstruction, including volume depletion and strenuous exertion
- treatment of HOCM (with LVOT obstruction)
 - medical agents: beta-blockers, disopyramide, verapamil (only in patients without resting or provokable obstruction)
 - avoid nitrates, diuretics and ACEI as they decrease outflow tract diameter and worsen symptoms
- patients with drug-refractory symptoms
 - surgical myectomy
 - septal ethanol ablation
 - dual chamber pacing
- treatment of ventricular arrhythmias: amiodarone or ICD
- first-degree relatives of patients with HCM should be screened annually during adolescence (physical, ECG, 2D echo), then serially every 5 years

Prognosis

- potential complications: AF, VT, CHF, sudden death (most common cause of SCD in young athletes)
- major risk factors for sudden death (consider ICD placement)
 - history of survived cardiac arrest/sustained VT
 - family history of multiple premature sudden deaths
 - other factors associated with increased risk of sudden cardiac death
 - ♦ syncope
 - ♦ non-sustained VT on ambulatory monitoring
 - ♦ marked ventricular hypertrophy (maximum wall thickness ≥ 30 mm)
 - ♦ abnormal BP in response to exercise (in young patients with HCM)

Restrictive Cardiomyopathy (RCM)

Definition

- impaired ventricular filling with usually intact systolic function in a non-dilated, non-hypertrophied ventricle 2° to myocardial abnormality (stiffening, fibrosis and/or decreased compliance)
- usually with intact systolic function initially

Etiology

- infiltrative: amyloidosis, sarcoidosis
- non-infiltrative: scleroderma, idiopathic myocardial fibrosis
- storage diseases: hemochromatosis, Fabry's disease, Gaucher's disease, glycogen storage diseases
- endomyocardial
 - endomyocardial fibrosis, Loeffler's endocarditis or eosinophilic endomyocardial disease
 - radiation heart disease
 - carcinoid syndrome (may have associated TV or PV dysfunction)

Clinical Manifestations

- CHF (usually with preserved LV systolic function), arrhythmias
- elevated JVP with prominent x and y descents, Kussmaul's sign
- S3, S4, MR, TR
- thromboembolic events

Investigations

- ECG: low voltage, non-specific, diffuse ST-T wave changes \pm non-ischemic Q waves
- CXR: mild cardiac enlargement
- echo: LAE, RAE; specific Doppler finding with no significant respiratory variation
- cardiac catheterization: increased end-diastolic ventricular pressures
- endomyocardial biopsy: to determine etiology (especially for infiltrative RCM)

Management

- exclude constrictive pericarditis
- treat underlying disease: control HR, anticoagulate if atrial fibrillation
- supportive care and treatment for CHF, arrhythmias
- heart transplant: might be considered for CHF refractory to medical therapy

Prognosis

- depends on etiology

Valvular Heart Disease

Infective Endocarditis (IE)

- see [Infectious Diseases](#), ID14
- AHA 2007 guidelines recommend IE prophylaxis
 - only for patients with prosthetic valve material, past history of IE, certain types of congenital heart disease or cardiac transplant recipients who develop valvulopathy
 - only for the following procedures
 - ♦ dental
 - ♦ respiratory tract
 - ♦ procedures on infected skin/skin structures/MSK structures
 - ♦ **not GI/GU procedures specifically**

Rheumatic Fever

- see [Pediatrics](#), P57

Prognosis

- acute complications: myocarditis (DCM/CHF), conduction abnormalities (sinus tachycardia, AF), valvulitis (acute MR), acute pericarditis (not constrictive pericarditis)
- chronic complications: rheumatic valvular heart disease – fibrous thickening, adhesion, calcification of valve leaflets resulting in stenosis/regurgitation, increased risk of IE ± thromboembolism
- onset of symptoms usually after 10-20 year latency from acute carditis of rheumatic fever
- mitral valve most commonly affected

Choice of Valve Prosthesis

A Bedside Clinical Prediction Rule for Detecting Moderate or Severe Aortic Stenosis

Etchells E, Glenns V, Shadowitz S, Bell C, Siu S. *J Gen Intern Med* 1998; 13(10):699-704. Department of Medicine, Toronto Hospital, ON, Canada.

Type: Blinded cross sectional study.

Who: 124 patients of an ambulatory cardiology clinic. Patients were examined for: 1) murmur over the right clavicle 2) murmur loudest at second right intercostal space 3) reduced intensity of S2 4) reduced volume of the carotid pulse 5) delayed carotid upstroke.

Methods: Patients were examined by blinded investigators, and the clinical examination findings were compared to findings on subsequent echocardiography. Moderate to severe aortic stenosis was defined as a valve area $<1.2 \text{ cm}^2$ or a peak intensity gradient of $>25 \text{ mmHg}$.

Results: Absence of a murmur over the right clavicle ruled out aortic stenosis while presence of ≥ 3 of the 4 associated symptoms ruled in aortic stenosis (LR=40).

Conclusions: Bedside techniques can accurately rule in and rule out moderate to severe aortic stenosis.

Table 14. Mechanical Valve vs. Bioprosthetic Valve

Mechanical Valve	Bioprosthetic Valve
<ul style="list-style-type: none"> • Good durability • Less preferred in small aortic root (stenotic) • Increased risk of thromboembolism (1-3%/year): long-term anticoagulation with coumadin • Target INR aortic valves: 2.0-3.0 mitral valves: 2.5-3.5 • Increased risk of hemorrhage: 1-2%/year 	<ul style="list-style-type: none"> • Limited long-term durability (mitral < aortic) • Good flow in small aortic root sizes • Decreased risk of thromboembolism: long-term anticoagulation not needed for aortic valves • Some recommendation for limited anticoagulation for mitral valves • Decreased risk of hemorrhage

Summary of Valvular Disease

Table 15. Valvular Heart Disease

AS

Etiology

Congenital (bicuspid, unicuspid valve), calcification (wear and tear), rheumatic disease

Aortic valve area: $N=3-4 \text{ cm}^2$

Mild AS $1.5 \text{ to } 3 \text{ cm}^2$

Moderate AS $1.0 \text{ to } 1.5 \text{ cm}^2$

Severe AS $<1.0 \text{ cm}^2$

Critical AS $<0.5 \text{ cm}^2$

Pathophysiology

Outflow obstruction \rightarrow increased EDP \rightarrow concentric LVH \rightarrow LV failure \rightarrow CHF, subendocardial ischemia

Symptoms

Exertional angina, syncope, dyspnea, PND, orthopnea, peripheral edema

Physical Exam

Narrow pulse pressure, brachial-radial delay, pulsus parvus et tardus, sustained PMI
Auscultation: crescendo-decrescendo SEM radiating to R clavicle and carotid, musical quality at apex (Gallavardin phenomenon), S₄, soft S₂ w/paradoxical splitting, S₃ (late)

Investigations

ECG: LVH and strain, LBBB, LAE, AF

CXR: post-stenotic aortic root dilatation, calcified valve, LVH, LAE, CHF

ECHO: reduced valve area, pressure gradient, LVH, reduced LV function

Treatment

Asymptomatic: serial Echos, avoid exertion

Symptomatic: avoid nitrates/arterial dilators and ACEIs in severe AS

Surgery if: symptomatic or LV dysfunction

Surgical Options

Valve replacement: aortic rheumatic valve disease and trileaflet valve

– Pregnancy

– Balloon valvuloplasty (in very young)

AR

Etiology

Supravalvular: aortic root disease (Marfan's, atherosclerosis and dissecting aneurysm, connective tissue disease)

Valvular: congenital (bicuspid AV, large VSD), IE

Acute Onset: IE, aortic dissection, trauma, failed prosthetic valve

Pathophysiology

Volume overload \rightarrow LV dilatation \rightarrow increased SV, high sBP and low dBP \rightarrow increased wall tension \rightarrow pressure overload \rightarrow LVH (low dBP \rightarrow decreased coronary perfusion)

Symptoms

Usually only becomes symptomatic late in disease when LV failure develops

Dyspnea, orthopnea, PND, syncope, angina

Physical Exam

Waterhammer pulse, bisferiens pulse, femoral-brachial sBP >20 (Hill's test wide pulse pressure), hyperdynamic apex, displaced PMI, heaving apex

Auscultation: early decrescendo diastolic murmur at LLSB (cusp) or RLSB (aortic root), best heard sitting, leaning forward, on full expiration, soft S₁, absent S₂, S₃ (late)

Investigations

ECG: LVH, LAE

CXR: LVH, LAE, aortic root dilatation

Echo/TTE: quantify AR, leaflet or aortic root anomalies

Cath: if >40 yrs and surgical candidate – to assess for ischemic heart disease

Exercise testing: hypotension with exercise

Treatment

Asymptomatic: serial Echos, afterload reduction (e.g. ACEIs, nifedipine, hydralazine)

Symptomatic: avoid exertion, treat CHF

Surgery if: NYHA class III-IV CHF, LVEF $<50\%$ with/without symptoms, increasing LV size

Surgical Options

Valve replacement: most patients

Valve repair: very limited role

Aortic root replacement (Bentall procedure):

– When ascending aortic aneurysm present, valved conduit used

MS

Etiology

Rheumatic disease most common cause; congenital (rare)

Severe MS is MVA $<1.2 \text{ cm}^2$

Pathophysiology

MS \rightarrow fixed CO and LAE \rightarrow increased LA pressure \rightarrow pulmonary vascular resistance and CHF; worse with AF (no atrial kick), tachycardia (decreased atrial emptying time) and pregnancy (increased preload)

Symptoms

SOBOE, orthopnea, fatigue, palpitations, peripheral edema, malar flush, pinched and blue facies (severe MS)

Physical Exam

AF, no "a" wave on JVP, left parasternal lift, palpable diastolic thrill at apex

Auscultation: mid-diastolic rumble at apex, best with bell in LLD position following exertion, loud S₁, OS following loud P₂ (heard best during expiration), long murmur and short A2-OS interval correlate with worse MS

Investigations

ECG: NSR/AF, LAE (P mitrale), RVH, RAD

CXR: LAE, CHF, MV calcification

Echo/TTE: restricted opening of MV

Cath: concurrent CAD if >40 yrs (male) or >50 yrs (female)

Treatment

Avoid exertion, fever (increased LA pressure), treat AF and CHF, increase diastolic filling time (beta-blockers, digitalis)

Surgery if: NYHA class III-IV CHF and failure of medical therapy (usually MVA $<1.2 \text{ cm}^2$)

Invasive Options

Percutaneous balloon valvuloplasty: young rheumatic pts and good leaflet morphology, asymptomatic pts with mod-sev MS, new-onset AF, pulmon HTN

Contraindication: Left atrial thrombus, moderate MR

Open Mitral Commissurotomy: If mild calcif + leaflet/chordal thickening

– restenosis in 50% pts in 8 yrs

Valve replacement: mod-sev calcif and sev scarred leaflets

MR

Etiology

Mitral valve prolapse

Congenital cleft leaflets, LV

dilatation/aneurysm (CHF, DCM, myocarditis), IE abscess, Marfan's

syndrome, HOCM, acute MI, myxoma, MV annulus calcification, chordae/papillary muscle trauma/ischemia/rupture, rheumatic disease

Pathophysiology

Reduced CO \rightarrow increased LV and LA pressure \rightarrow LV and LA dilatation \rightarrow CHF and pulmonary HTN

Symptoms

Dyspnea, PND, orthopnea, palpitations, peripheral edema

Physical Exam

Displaced, hyperdynamic apex, left parasternal lift, apical thrill

Auscultation: holosystolic murmur at apex, radiating to axilla \pm mid-diastolic rumble, loud S₂ (if pulmonary HTN), S₃

Investigations

ECG: LAE, left atrial delay (bifid P waves), \pm LVH

CXR: LVH, LAE, pulmonary venous HTN

Echo: severity of MR, LV function, leaflets

Swan-Ganz: prominent LA "v" wave

Treatment

Asymptomatic: serial Echos,

Symptomatic: decrease preload (diuretics), decrease afterload (ACEIs) for severe MR and poor surgical candidate; stabilize acute MR with vasodilators before surgery

Surgery if: acute MR with CHF, papillary muscle rupture, NYHA class III-IV CHF, AF, LVEF $<60\%$, increasing LV size, earlier surgery if valve repairable

Surgical Options

Valve repair: $>75\%$ of pts with MR and myxomatous MV disease (MVP)

– annuloplasty rings, leaflet repair, chordae transfers/shorten/replacement

Valve replacement: failure of repair, heavily calcified annulus

Advantage of repair: low rate of endocarditis, no anticoagulation, less chance of re-operation

Table 15. Valvular Heart Disease (continued)**TS****Etiology**

Rheumatic disease, congenital, carcinoid, fibroelastosis; usually accompanied by MS

Pathophysiology

Increased RA pressure → right heart failure → decreased CO and fixed on exertion

Symptoms

Peripheral edema, fatigue, palpitations

Physical Exam

Prominent “a” waves in JVP, +ve abdominojugular reflex, Kussmaul’s sign, diastolic rumble 4th left intercostal space

Investigations

ECG: RAE

CXR: dilatation of RA without pulmonary artery enlargement

Echo: diagnostic

Treatment

Preload reduction (diuretics)

Surgery if: usually only if other surgery needed (e.g. MVR)

Surgical Options

Valve Replacement:

- If severely diseased valve
- Bioprosthesis preferred

**TR****Etiology**

RV dilatation, IE (IV drug use), rheumatic disease, congenital (Ebstein anomaly), carcinoid

Pathophysiology

RV dilatation → TR → further RV dilatation → right heart failure

Symptoms

Peripheral edema, fatigue, palpitations

Physical Exam

“cv” waves in JVP, +ve abdominojugular reflex, Kussmaul’s sign, holosystolic murmur at LLSB accentuated by inspiration, left parasternal lift

Investigations

ECG: RAE, RVH, AF

CXR: RAE, RV enlargement

Echo: diagnostic

Treatment

Preload reduction (diuretics)

Surgery if: usually only if other surgery needed (e.g. MVR)

Surgical Options

Annuloplasty, i.e. repair (rarely replacement)

**PS****Etiology**

Usually congenital, rheumatic disease (rare), carcinoid

Pathophysiology

Increased RV pressure → RV hypertrophy → right heart failure

Symptoms

Chest pain, syncope, fatigue, peripheral edema

Physical Exam

Systolic murmur at 2nd LICS accentuated by inspiration, pulmonary ejection click, right-sided S4

Investigations

ECG: RVH

CXR: prominent pulmonary arteries enlarged RV

Echo: diagnostic

Treatment

Balloon valvuloplasty if severe symptoms

Surgical Options

Percutaneous or open balloon valvuloplasty

**PR****Etiology**

Pulmonary HTN, IE, rheumatic disease, tetralogy of Fallot (post-repair)

Pathophysiology

Increased RV volume → increased wall tension → RV hypertrophy → right heart failure

Symptoms

Chest pain, syncope, fatigue, peripheral edema

Physical Exam

Early diastolic murmur at LLSB, Graham Steell (diastolic) murmur 2nd and 3rd LICS increasing with inspiration

Investigations

ECG: RVH

CXR: prominent pulmonary arteries if pulmonary HTN; enlarged RV

Echo: diagnostic

Treatment

Rarely requires treatment; valve replacement if severe

Surgical Options

Pulmonary valve replacement

**Mitral Valve Prolapse****Etiology**

Myxomatous degeneration of chordae; thick, bulky leaflets that crowd orifice; Marfan’s syndrome; pectus excavatum, straight back syndrome, other MSK abnormalities; <3% of population

Pathophysiology

MV displaced into LA during systole; no causal mechanisms found for symptoms

Symptoms

Prolonged, stabbing chest pain, dyspnea, anxiety/panic, palpitations, fatigue, presyncope

Physical Exam

Auscultation: mid-systolic click (billowing of mitral leaflet into LA; tensing of redundant valve tissue); mid to late systolic murmur at apex, accentuated by Valsalva or squat-to-stand maneuvers

Investigations

ECG: non-specific ST-T wave changes, paroxysmal SVT, ventricular ectopy

Echo: systolic displacement of thickened MV leaflets into LA

Treatment

Asymptomatic: no treatment; reassurance

Symptomatic: beta-blockers and avoidance of stimulants (caffeine) for significant palpitations, anticoagulation if systemic emboli

Surgical Options

Mitral valve surgery (repair favoured over replacement) if symptomatic and significant MR

Figure 33. Hemodynamics of Aortic Stenosis

Stenosis across the aortic valve results in the generation of a significant pressure gradient between the left ventricle and the aorta and a crescendo-decrescendo murmur during systolic contraction. The stenosis decreases the intensity of aortic valve closure hence diminishing S2.

Figure 34. Hemodynamics of Aortic Regurgitation

Regurgitation across the aortic valve during diastole causes the aortic pressure to rapidly decrease and a decrescendo murmur can be heard at the onset of diastole (after S2 is audible). The presence of regurgitant blood from the aorta increases left-ventricular end-diastolic volume.

Figure 35. Hemodynamics of Acute Mitral Regurgitation

During systolic contraction, blood regurgitates from the left ventricle into the left atrium across the incompetent mitral valve resulting in an audible holosystolic murmur between S1 and S2. The portion of left ventricular end diastolic volume that regurgitates into the left atrial myocardium increases left atrial pressures resulting in a tall V-wave.

Figure 36. Hemodynamics of Mitral Stenosis

First note that the left atrial pressure exceeds the left ventricular pressure during diastole due to mitral stenosis and the consequent generation of a pressure gradient across the left atrium and left ventricle. In diastole, the stenotic mitral valve opens which corresponds to the opening snap (OS) and the passage of blood across the mitral stenosis results in an audible decrescendo murmur. Left atrial contraction prior to S1 increases the pressure gradient resulting in accentuation of the murmur before S1 is audible.

Pericardial Disease

Acute Pericarditis

Etiology of Pericarditis/Pericardial Effusion

- idiopathic is most common: usually presumed to be viral
- infectious
 - viral: Coxsackie virus A, B (most common), echovirus
 - bacterial: *S. pneumoniae*, *S. aureus*
 - TB
 - fungal: histoplasmosis, blastomycosis
- post-MI: acute (direct extension of myocardial inflammation, 1-7 days), Dressler's syndrome (autoimmune, 2-8 weeks)
- post-cardiac surgery (e.g. CABG), other trauma
- metabolic: uremia (common), hypothyroidism
- neoplasm: Hodgkin's, breast, lung, renal cell carcinoma, melanoma
- collagen vascular disease: SLE, polyarteritis, RA, scleroderma
- vascular: dissecting aneurysm
- other: drugs (e.g. hydralazine), radiation, infiltrative disease (sarcoid)

Signs and Symptoms

- diagnostic triad: chest pain, friction rub, and ECG changes
- pleuritic chest pain – alleviated by sitting up and leaning forward
- pericardial friction rub – may be uni-, bi- or triphasic
- \pm fever, malaise

Investigations

- ECG: initially diffuse elevated ST segments \pm depressed PR segment, the elevation in the ST segment is concave upwards \rightarrow 2-5 days later ST isoelectric with T wave flattening and inversion
- CXR: normal heart size, pulmonary infiltrates
- echo: assess pericardial effusion

Treatment

- treat the underlying disease
- anti-inflammatory agents (high dose NSAIDs/ASA, steroids if severe or recurrent); analgesics

Prognosis

- complications: recurrence, atrial arrhythmia, pericardial effusion, tamponade, constrictive pericarditis

Pericardial Effusion

Etiology

- transudative (serous)
 - CHF, hypoalbuminemia/hypoproteinemia, hypothyroidism
- exudative (serosanguinous or bloody)
 - causes similar to the causes of acute pericarditis
 - may develop acute effusion secondary to hemopericardium (trauma, post-MI myocardial rupture, aortic dissection)
- physiologic consequences depend on type and volume of effusion, rate of effusion development, and underlying cardiac disease

Signs and Symptoms

- may be asymptomatic or similar to acute pericarditis
- dyspnea, cough
- extra-cardiac (esophageal/recurrent laryngeal nerve/tracheo-bronchial/phrenic nerve irritation)
- JVP increased with dominant "x" descent
- arterial pulse normal to decreased volume, decreased pulse pressure
- auscultation: distant heart sounds \pm rub

Investigations

- ECG: low voltage, flat T waves
- CXR: cardiomegaly, rounded cardiac contour
- echo (procedure of choice): fluid in pericardial sac
- pericardiocentesis: definitive method of determining transudate vs. exudate, identify infectious agents, neoplastic involvement

Treatment

- mild: frequent observation with serial echocardiograms, treat underlying cause, anti-inflammatory agents for inflammation
- severe: may develop cardiac tamponade

Acute Pericarditis
Chest Pain
Friction Rub
ECG Changes

Ewart's Sign
Bronchial breathing and dullness to percussion at the lower angle of the left scapula in pericardial effusion due to effusion compressing left lower lobe of lung.

Cardiac Tamponade

Etiology

- major complication of rapidly accumulating pericardial effusion; cardiac tamponade is a clinical diagnosis
- any cause of pericarditis but especially trauma, malignancy, uremia, idiopathic, proximal aortic dissection with rupture

Pathophysiology

- high intra-pericardial pressure → decreased venous return → decreased diastolic ventricular filling → decreased CO → hypotension and venous congestion

Signs and Symptoms

- tachypnea, dyspnea, shock, muffled heart sounds
- pulsus paradoxus (inspiratory fall in systolic BP >10 mmHg during quiet breathing)
- JVP “x” descent only, absent “y” descent
- hepatic congestion/peripheral edema

Investigations

- ECG: electrical alternans (pathognomonic variation in R wave amplitude), low voltage
- echo: pericardial effusion, compression of cardiac chambers (RA and RV) in diastole
- cardiac catheterization

Treatment

- pericardiocentesis – echo- or ECG-guided
- pericardiectomy
- avoid diuretics and vasodilators (these decrease venous return to already under-filled RV → decrease LV preload → decrease CO)
- fluid administration i.e. saline load may temporarily increase CO
- treat underlying cause

Classic quartet of tamponade: hypotension, increased JVP, tachycardia, pulsus paradoxus.

Beck's Triad: hypotension, increased JVP, muffled heart sounds.

DDx Pulsus Paradoxus

- Constrictive pericarditis
- Severe obstructive pulmonary disease (e.g. asthma)
- Tension Pneumothorax
- Pulmonary embolus
- Cardiogenic shock

Constrictive Pericarditis

Etiology

- chronic pericarditis resulting in fibrosed, thickened, adherent, and/or calcified pericardium
- any cause of acute pericarditis may result in chronic pericarditis
- major causes are idiopathic, post-infectious (viral, TB), radiation, post-cardiac surgery, uremia, MI

Signs and Symptoms

- dyspnea, fatigue, palpitations
- abdominal pain
- may mimic CHF (especially right-sided HF)
 - ascites, hepatosplenomegaly, edema
- increased JVP, Kussmaul's sign (paradoxical increase in JVP with inspiration), Friedreich's sign (prominent “y” descent)
- BP usually normal (and usually no pulsus paradoxus)
- precordial examination: ± pericardial knock (early diastolic sound)
- see Table 16 for differentiation from cardiac tamponade

Investigations

- ECG: non-specific: low voltage, flat T wave, ± AF
- CXR: pericardial calcification, effusions
- echo/CT/MRI: pericardial thickening
- cardiac catheterization: equalization of end-diastolic chamber pressures (diagnostic)

Treatment

- medical: diuretics, salt restriction
- surgical: pericardiectomy (only if refractory to medical therapy)
- prognosis best with idiopathic or infectious cause and worst in post-radiation with death resulting from heart failure

Table 16. Differentiation of Constrictive Pericarditis vs. Cardiac Tamponade

Characteristic	Constrictive Pericarditis	Tamponade
JVP	“y” > “x”	“x” > “y”
Kussmaul's sign	Present	Absent
Pulsus paradoxus	Uncommon	Always
Pericardial knock	Present	Absent
Hypotension	Variable	Severe

VASCULAR DISEASE

Peripheral Arterial Disease

Acute Arterial Occlusion/Insufficiency

Definition

- acute occlusion/rupture of a peripheral artery
- urgent management required: >6 hours results in irreversible ischemia and myonecrosis
- lower extremity > upper extremity; femoropopliteal > aortoiliac

Etiology

- embolus
 - cardiac embolus (80-90%): history of MI <3 months, valvular disease, AF, cardiomyopathy, endocarditis, atrial myxoma
 - arterial embolus: proximal arterial aneurysm, atheroembolism
 - venous embolus (intracardiac shunt); may have Hx of OCP use
 - Hx of TIAs/strokes
- thrombus
 - atherosclerotic, congenital anomaly, infection, hematological disorders and stasis
- trauma
 - arterial catheterization, intra-arterial drug injection induced, aortic dissection, severe venous thrombophlebitis, prolonged immobilization
- idiopathic

Clinical Features

- general
 - pain in lower extremity progressing within hours to a feeling of cold, numbness, loss of function and sensation
 - symptoms (6 P's) – all may not be present
 - ♦ Pain: absent in 20% of cases due to prompt onset of anesthesia and paralysis
 - ♦ Pallor: within a few hours becomes mottled cyanosis
 - ♦ Paresthesia: light touch (small fibres) lost first then sensory modalities (large fibres)
 - ♦ Paralysis/Power loss: most important, heralds impending gangrene
 - ♦ Polar (cold)
 - ♦ Pulselessness: not reliable
- embolus vs. thrombus – dramatically different treatment (see Table 17)

Investigations

- CXR, ECG, arteriography

Treatment

- immediate heparinization with 5000 IU bolus and continuous infusion to maintain PTT >60 seconds
- absent power and sensation – emergent revascularization
- present power and sensation – work-up (including angiogram)
- definitive treatment
 - embolus: embolectomy
 - thrombus: thrombectomy ± graft, ± bypass
 - irreversible ischemia: amputation
- identify and treat underlying cause
- continue heparin post-op, start warfarin post-op day 1 for 3 months

Table 17. Differentiation of Arterial Embolism and Thrombosis

Presentation	Embolus	Thrombus
Onset	Acute	Progressive, acute-on-chronic
Loss of function/sensation	Prominent	Less profound
Hx of claudication	No	Yes
Atrophic changes	No	Yes
Contralateral limb pulses	Yes	Decreased or absent

Complications

- compartment syndrome with prolonged ischemia; requires fasciotomy
- renal failure and multi-organ failure due to toxic metabolites from ischemic muscle

Prognosis

- 12-15% mortality rate
- 5-40% morbidity rate (amputation)

Differential of Claudication

Vascular

- Atherosclerotic disease
- Vasculitis (e.g. Buerger's disease, Takayasu's arteritis)
- Diabetic neuropathy
- Venous disease (e.g. DVT, varicose veins)
- Popliteal entrapment syndrome

Neurologic

- Neurospinal disease (e.g. spinal stenosis)
- Reflex sympathetic dystrophy

MSK

- Osteoarthritis
- Rheumatoid arthritis/connective tissue disease
- Remote trauma

Chronic Arterial Occlusion/Insufficiency

Etiology

- predominantly due to atherosclerosis: primarily lower extremities with symptoms related to the location of obstruction

Risk Factors

- major: smoking, DM, hyperhomocysteinemia
- minor: HTN, hyperlipidemia, family history, obesity, sedentary lifestyle, male gender

Clinical Features

- claudication
 - pain with exertion: usually in calves or any exercising group
 - relieved by short rest: 2 to 5 minutes, and no postural changes necessary
 - reproducible: same distance to elicit pain, same location of pain, same amount of rest to relieve pain
- pulses may be absent at some locations, bruits may be present
- signs of poor perfusion: hair loss, hypertrophic nails, atrophic muscle, skin ulcerations and infections, slow capillary refill, prolonged pallor with elevation and rubor on dependency, venous troughing (collapse of superficial veins of foot)
- other manifestations of atherosclerosis: CVD, CAD, impotence, splanchnic ischemia

Signs of Peripheral Vascular Insufficiency

SICVD

Symmetry of leg musculature
Integrity of skin
Colour of toe nails
Varicose veins
Distribution of hair

Differential Diagnosis

- osteoarthritis (OA): worse at night and varies day-to-day
- neurogenic claudication: due to spinal stenosis or radiculopathy; pain very similar but relieved by longer rest and postural changes
- varicose veins: localized pain, typically less severe, after exercise and never at rest; related to the presence and site of varices
- inflammatory processes: Buerger's disease, Takayasu's arteritis
- other: popliteal entrapment (e.g. tumour, Baker's cyst), radiation injury, remote trauma

Investigations

- non-invasive
 - ankle-brachial index (ABI) (grade 1A recommendation): measure brachial and ankle pressures bilaterally (use highest value) generally, ABI <0.90 abnormal, rest pain appears at <0.3 (see Table 18)
 - CTA and MRA – excellent correlation with arteriography, where available, can replace it for intervention planning (grade 1A recommendation)
 - Doppler segmental pressures and pulse volume recordings, transcutaneous oxygen studies (photoplethysmography) treadmill exercise claudication test and real-time duplex scanning considered by vascular specialist (grade 3C)
- invasive
 - arteriography (gold standard): defines site and size of occlusion, and collateral flow status, operative planning tool

Table 18. Ankle-Brachial Indices and Degrees of Ischemia

ABI recording	Degree of Ischemia
>0.95	Normal/no ischemia
0.85 – 0.94	Mild
0.50 – 0.84	Moderate
0.26 – 0.49	Severe
<0.25	Consider limb salvage
>1.2	Suspect wall calcification (most common in diabetics)

Treatment (see Figure 37)

- conservative
 - risk factor modification (smoking cessation improves prognosis, treatment of HTN, hyperlipidemia and/or DM)
 - exercise program – develops collateral circulation, improves exercise tolerance
 - foot care (especially DM)
- pharmacotherapy
 - anti-platelet agents (ECASA, clopidogrel or more rarely ticlopidine)
 - cilostazol (cAMP-phosphodiesterase inhibitor with anti-platelet and vasodilatory effects)
 - pain relief: opiate analgesia (morphine sulphate), supplemented by NSAIDs; if opiate analgesia inadequate, possibility of lumbar sympathectomy

- surgical/interventional
 - indications: claudication interfering with lifestyle, rest pain, pre-gangrene, gangrene
 - surgical options: endovascular (stenting/angioplasty) or arterial bypass grafts
 - bypass graft sites: aortofemoral, axillofemoral, femoropopliteal, distal arterial
 - graft choices: in situ graft – reversed vein graft, synthetic – polytetrafluoroethylene graft (Gor-Tex®) or Dacron®
 - amputation: if not suitable for revascularization and persistent serious infections and/or gangrene

Prognosis

- conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 years, <4% will require amputation

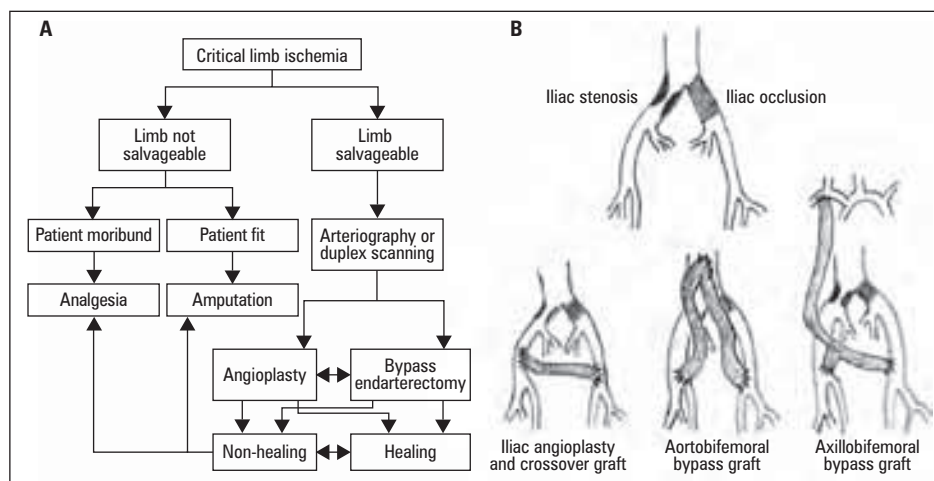

Figure 37. Treatment Options for Critical Limb Ischemia

(A) Algorithm for the treatment of critical limb ischemia

(B) Surgical treatment options for the treatment of aortoiliac disease

Modified from Beard JD. Chronic lower limb ischemia. *BMJ*. 2000; 320:854-857.

Hypertension

- see [Family Medicine](#), FM35

Pulmonary Hypertension

- see [Respirology](#), R16

Carotid Artery Disease

- see [Neurosurgery](#), NS21

Aortic Disease

Aortic Dissection

Definition

- tear in aortic intima allowing blood to dissect into the media; acute <2 weeks (initial mortality 1% per hour), chronic >2 weeks (mortality levels off to 75-80%)

Classification (see Figure 38)

- Stanford
 - Type A: involves ascending aorta ± aortic arch; requires emergency surgery
 - Type B: only involves aorta distal to subclavian artery; emergency surgery only if complications of dissection (requires long-term follow-up to assess aneurysm size)

- DeBakey
 - Type I: involves ascending and descending aorta, 50% of patients
 - Type II: ascending aorta only (stops at the innominate artery), 35% of patients
 - Type IIIA: descending thoracic aorta only (distal to left subclavian artery and proximal to diaphragm), 15% of patients (including Type IIIB)
 - Type IIIB: Type IIIA plus abdominal aorta

Figure 38. Classification of Aortic Dissection

Etiology

- most common: damage to aortic media (smooth muscle and elastic tissue), leading to degenerative/cystic changes due to hypertension
- other: cystic medial necrosis, atherosclerosis, connective tissue disease (Marfan's, Ehlers-Danlos), congenital conditions (coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection, trauma, arteritis (Takayasu's)

Epidemiology

- incidence of 5.2 in 1 000 000
- male:female = 3.2:1
- small increased incidence in African-Canadians (related to higher incidence of hypertension)
- lowest incidence in Asians
- peak incidence 50-65 yrs old; 20-40 yrs old with connective tissue diseases

Clinical Features

- sudden onset tearing chest pain that radiates to back with
 - hypertension (75-85% of patients)
 - asymmetric BPs and pulses between arms (>30 mmHg difference indicates poor prognosis)
 - ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotids (ischemic stroke, Horner's syndrome), splanchnic (ischemic gut)
 - "unseating" of aortic valve cusps (new diastolic murmur in 20-30%)
 - rupture into pleura (dyspnea, hemoptysis) or peritoneum (hypotension, shock) or pericardium (cardiac tamponade)
 - renal insufficiency
 - lower limb ischemia (cold legs)
 - syncope

Investigations

- CXR
 - pleural cap (pleural effusion in lung apices)
 - widened mediastinum
 - left pleural effusion with extravasation of blood
- TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta
- ECG: LVH, \pm MI, pericarditis, heart block
- CT, aortography, MRA: 100% sensitive and specific
- bloodwork: LDH (r/o ischemic gut), amylase (r/o pancreatitis), troponin (r/o MI)

Treatment

- pharmacologic
 - sodium nitroprusside and beta-blocker to lower BP and decrease cardiac contractility
 - beta-blocker given first to blunt reflex tachycardia and inotropy that will occur with sodium nitroprusside (vasodilator) then lower sBP with nitroprusside
 - target sBP of 110mmHg and HR of 60 bpm

- surgical
 - resection of intimal tear, reconstitution of flow through true lumen, replacement of the affected aorta with prosthetic graft, correction of any predisposing factors (e.g. bicuspid aortic valve, PDA, etc.)
 - post-operative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
 - 2/3 of patients die of operative or post-operative complications
 - Type A: requires emergent surgery with cardiopulmonary bypass, may require hypothermic circulation for transverse arch dissections, valve replacement and coronary re-implantation for aortic root involvement, initial mortality rate without surgery is 3% per hour for first 24 hours, 30% 1 week, 80% 2 weeks
 - Type B: initially managed medically – 10-20% require urgent operation for complications (expansion, rupture, compromise of branch arteries, refractory HTN, or ongoing pain)
 - with treatment, 60% 5 yr survival, 40% 10 yr survival

Aortic Aneurysm

Definition of Aneurysm

- localized dilatation of an artery having a diameter at least 1.5 times that of the expected normal diameter of that given aortic segment
 - true aneurysm: involving all vessel wall layers (intima, media and adventitia)
 - false aneurysm: disruption of the aortic wall or the anastomotic site between vessel and graft with containment of blood by fibrous capsule made of surrounding tissue
- aneurysms can rupture, thrombose, embolize or erode and fistulize

Classification

- thoracic (TAA): ascending, transverse arch, descending
- thoracoabdominal
- abdominal (AAA): 90-98% are infrarenal

Etiology

- degenerative
- atherosclerotic
- traumatic
- mycotic (*Salmonella*, *Staphylococcus*, usually suprarenal)
- connective tissue disorder (Marfan syndrome, Ehlers-Danlos)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic are associated with bicuspid aortic valve
- risk factors: smoking, HTN, age >70, family history

Epidemiology

- incidence 4.7 to 31.9 per 100 000 for AAA and 5.9 per 100 000 for TAA
- high risk groups
 - 65 years and older
 - male:female = 3.8:1
 - PVD, CAD, CVD
 - family history of AAA

Clinical Features

- common presentation: due to acute expansion or disruption of wall
 - syncope
 - pain (chest, abdominal, flank, back)
 - hypotension
 - palpable pulsatile mass above the umbilicus, pulsatile abdominal mass in two directions
 - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemesis
 - distal pulses may be intact
- 75% asymptomatic (discovered incidentally)
- uncommon presentation
 - partial bowel obstruction
 - ureteric obstruction and hydronephrosis
 - GI bleed (duodenal mucosal hemorrhage, aortoduodenal fistula)
 - aortocaval fistula
 - distal embolization (blue toe)
- associated diseases
 - hypertension, PVD, CAD, COPD, renal insufficiency
- most commonly in the abdominal aorta (50% abdominal aorta, 40% thoracic aorta, 10% ascending aorta)

ACC/AHA 2005 Guidelines define an AAA when the minimum AP diameter of abdominal aorta ≥ 3.0 cm.

Classic Triad of Ruptured AAA

- Pain
- Hypotension
- Pulsatile abdominal mass

ACC/AHA 2005 Guidelines Suggest

1. Men ≥ 60 yrs with AAA in first-degree relative should have U/S screening for AAA.
2. Men 60-75 yrs who have ever smoked should have one-time U/S screening for AAA.

Investigations

- bloodwork: CBC, electrolytes, urea, creatinine, PTT, INR, type and cross
- abdominal U/S (100% sensitive, up to ± 0.6 cm accuracy in size determination)
- CT (accurate visualization, size determination)
- MRI (accurate visualization, limited access)
- aortogram
- Doppler/duplex (r/o vascular tree aneurysms elsewhere)

Treatment**Conservative**

- cardiovascular risk factor reduction: smoking cessation, HTN control, DM and hyperlipidemia control
- regular exercise
- watchful waiting, U/S every 6 months to 3 years depending on size and location

Surgical

- when risk of rupture greater than or equal to risk of surgery (>5.5 cm)
- risk of rupture depends on
 - size
 - rate of enlargement >0.4 cm/yr
 - symptoms, comorbidities (HTN, COPD, dissection), smoking
- elective AAA repair mortality 2-5%; elective TAA repair mortality $<10\%$ (highest with proximal aortic and thoracoabdominal repairs)
- consider revascularization for patients with CAD before elective repair of aneurysm
- indications
 - general: ruptured, symptomatic, mycotic, associated with acute Type A dissection or complicated Type B dissection or when risk of rupture is greater than risk of surgery (size >5.5 cm or $>2\times$ normal lumen size)
 - ascending thoracic aortic aneurysms
 - ♦ symptomatic, enlarging, diameter >5.5 cm or $>2\times$ normal lumen size, >4.5 cm and aortic regurgitation (annuloaortic ectasia); ≥ 5 cm in Marfan syndrome
- contraindications: life expectancy <1 year, terminal disease (e.g. cancer), significant co-morbidities (recent MI, unstable angina), decreased mental acuity, advanced age
- surgical options
 - open surgery (laparotomy) with graft replacement
 - ♦ possible complications
 - early: renal failure, spinal cord injury (paraparesis or paraplegia), impotence, arterial thrombosis, anastomotic rupture or bleeding, peripheral emboli
 - late: graft infection/thrombosis, aortoenteric fistula, anastomotic (pseudo) aneurysm
 - endoluminal graft placement under image guidance
 - ♦ newer procedure; high success rates in patients with suitable anatomy and experienced centres
 - ♦ advantages: decreased morbidity and mortality, procedure time, need for transfusion, ICU admissions, length of hospitalization, and recovery time
 - ♦ disadvantages: endoleak rates as high as 20-30%, device failure increasing as longer follow-up periods are achieved, re-intervention rates 10-30%, cost-effectiveness is an issue (devices are very expensive)
 - ♦ complications
 - early: immediate conversion to open repair, groin hematoma, arterial thrombosis, iliac artery rupture, and thromboemboli
 - late: endoleak, severe graft kinking, migration, thrombosis, rupture of aneurysm

**Management of Ruptured AAA**

- No imaging
- Straight to OR (confirm diagnosis by laparotomy)
- Crossmatch 10 units PRBCs
- Start IV if possible

**Risk of AAA Rupture**

Size	1-year rupture risk
<4 cm	0%
4-4.9 cm	1%
5-5.9 cm	5-10%
6-6.9 cm	10-20%
7-7.9 cm	20-40%

**Repair of Asymptomatic AAA is Generally Not Justified for:**

- Males <5.0 cm
- Females <4.5 cm

Peripheral Venous Disease

Deep Venous Thromboembolism

- see Hematology, H31

Superficial Thrombophlebitis

Definition

- erythema, induration, and tenderness along the superficial vein; usually spontaneous but can follow venous cannulation

Migratory superficial thrombophlebitis is often a sign of underlying malignancy ("Trousseau's disease").

Etiology

- infectious: suppurative phlebitis (complication of intravenous cannulation; associated with fever, chills)
- trauma
- inflammatory: varicose veins, migratory superficial thrombophlebitis, Buerger's disease, SLE
- hematologic: polycythemia, thrombocytosis
- neoplastic: occult malignancy (especially pancreatic)
- idiopathic

Clinical Features

- most common in greater saphenous vein and its tributaries
- pain and cord-like swelling along course of involved vein
- areas of induration, erythema and tenderness correspond to dilated and often thrombosed superficial veins
- complications
 - simultaneous DVT (up to 20% of cases), pulmonary embolus (rare unless DVT)
 - recurrent superficial thrombophlebitis

Investigations

- non-invasive tests (e.g. Doppler ultrasonography) to exclude associated DVT

Treatment

- conservative
 - bedrest and elevation of limb
 - moist heat, compression bandages, mild analgesic, anti-inflammatory and anti-platelet (e.g. ASA), ambulation
- surgical excision of involved vein
 - indication: failure of conservative measures (symptoms that persist over 2 weeks)
 - suppurative thrombophlebitis: broad-spectrum IV antibiotics and excision

Varicose Veins

Definition

- distention of tortuous superficial veins resulting from incompetent valves in the deep, superficial, or perforator systems
- distribution: greater saphenous vein and tributaries (most common), esophagus, anorectum, scrotum

Etiology

- primary
 - main factor: inherited structural weakness of valves
 - contributing factors: increasing age, female gender, OCP use, occupations requiring long hours of standing, pregnancy, obesity
- secondary
 - malignant pelvic tumours with venous compression
 - congenital anomalies – arteriovenous fistulae

Epidemiology

- most common form of venous disorder of lower extremity
- 10-20% of population

Clinical Features

- diffuse aching, fullness/tightness, nocturnal cramping
- aggravated by prolonged standing (end of day), premenstrual
- visible long, dilated and tortuous superficial veins along thigh and leg
- ulceration, hyperpigmentation, and induration (secondary varicosities)
- associated esophageal varices (GI bleed), hemorrhoids, varicocele
- Brodie-Trendelenberg test (valvular competence test)
 - with patient supine, raise leg and compress saphenous vein at thigh; have patient stand; if veins fill quickly from top down then incompetent valves; use multiple tourniquets to localize incompetent veins

Complications

- recurrent superficial thrombophlebitis
- hemorrhage: external or subcutaneous
- ulceration, eczema, lipodermatosclerosis, and hyperpigmentation

Treatment

- largely a cosmetic problem
- conservative: elevation of leg and/or elastic stockings
- surgical: high ligation and stripping of the long saphenous vein and its tributaries, sclerotherapy, endovenous laser therapy (EVLT)

Prognosis

- natural history benign, slow with predictable complications
- almost 100% symptomatic relief with treatment if varicosities are primary
- good cosmetic results with treatment
- significant post-operative recurrence, especially with sclerosing agent injection

Chronic Venous Insufficiency

Definition

- chronic elevation of deep venous pressure and blood pooling in lower extremities

Etiology

- calf muscle pump dysfunction and valvular incompetence (valvular reflux) due to phlebitis, varicosities, or DVT
- venous obstruction
- AV fistulas, venous malformations

Clinical Features

- pain (most common), ankle and calf edema – relieved by foot elevation
- pruritis, brownish hyperpigmentation (hemosiderin deposits)
- stasis dermatitis
- ulceration: shallow, above medial malleolus, weeping (wet), painless, irregular outline
- signs of DVT/varicose veins/thrombophlebitis

Investigations

- ambulatory venous pressure measurement (gold standard)
- Doppler U/S (most commonly used)
- photoplethysmography

Treatment

- conservative
 - elastic compression stockings, leg elevation, avoid prolonged sitting/standing
 - ulcers: zinc-oxide wraps, split-thickness skin grafts, antibiotics, debridement
- surgical
 - if conservative measures fail, or if recurrent/large ulcers
 - surgical ligation of perforators in region of ulcer, greater saphenous vein stripping
 - venous bypass if short segment obstruction

Lymphedema

Definition

- obstruction of lymphatic drainage resulting in edema with high protein content

Etiology

- primary: Milroy's syndrome
- secondary
 - infection: filariasis (#1 cause worldwide), post-operative
 - malignant infiltration: axillary, groin or intrapelvic
 - radiation/surgery (axillary, groin lymph node removal): #1 cause in North America

Clinical Features

- classically non-pitting edema
- impaired limb mobility; discomfort/pain; psychological distress

Treatment

- avoid limb injury (can precipitate or worsen lymphedema)
- skin hygiene
 - daily skin care with moisturizers
 - topical treatment of fungal infection; systemic treatment of bacterial infection
- external support
 - intensive: compression bandages
 - maintenance: lymphedema sleeve
- exercise
 - gentle daily exercise of affected limb, gradually increasing ROM
 - must wear a sleeve/bandages when doing exercises
- massage and manual lymph drainage therapy

Prognosis

- if left untreated, becomes resistant to treatment due to subcutaneous fibrosis
- cellulitis causes rapid increase in swelling: can lead to sepsis and death

Pitting edema → vascular
Non-pitting edema → lymphatic

Common Medications

Table 19. Commonly Used Cardiac Therapeutics

Drug Class	Examples	Mechanism of Action	Indications	Side Effects	Contraindications
ANGIOTENSIN CONVERTING ENZYME INHIBITORS (ACEIS)					
	enalapril (Vasotec®), perindopril (Coversyl®), ramipril (Altace®) lisinopril	Inhibit ACE-mediated conversion of angiotensin I to angiotensin II (AT II), causing peripheral vasodilation and decreased aldosterone synthesis	HTN, CAD, CHF, post-MI, DM	Dry cough, 10% hypotension, fatigue, hyperkalemia, renal insufficiency, angioedema	Bilateral renal artery stenosis, pregnancy, caution in decreased GFR
ANGIOTENSIN II RECEPTOR BLOCKERS (ARBs)					
	candesartan, irbesartan, valsartan	Block AT II receptors, causing similar effects to ACEIs	Same as ACEIs, although evidence is generally less for ARBs. Often used when ACEIs are not tolerated.	Similar to ACEIs, but do not cause dry cough	Same as ACEIs
β-BLOCKERS					
β ₁ antagonists	atenolol, metoprolol, bisoprolol	Block β-adrenergic receptors, decreasing HR, BP, contractility, and myocardial oxygen demand, slow conduction through the AV node	HTN, CAD, acute MI, post-MI, CHF (start low and go slow), AF, SVT	Hypotension, fatigue, light- headedness, depression, bradycardia, hyperkalemia, bronchospasm, impotence, depression of counterregulatory response to hypoglycemia, exacerbation of Raynaud's phenomenon and claudication	Sinus bradycardia, 2nd or 3rd degree heart block, hypotension, WPW. Caution in asthma, claudication, Raynaud's phenomenon, and decompensated CHF
β ₁ /β ₂ antagonists	propranolol				
α ₁ /β ₁ /β ₂ antagonists	labetalol, carvedilol				
β ₁ antagonists with ISA	acebutalol				
CALCIUM CHANNEL BLOCKERS (CCBS)					
Benzothiazepines Phenylalkylamines (non-dihydropyridines)	diltiazem verapamil	Block smooth muscle and myocardial calcium channels causing effects similar to β-blockers Also vasodilate	HTN, CAD, SVT, diastolic dysfunction	Hypotension, bradycardia, edema Negative inotrope	Sinus bradycardia, 2nd or 3rd degree heart block, hypotension, WPW, CHF
Dihydropyridines	amlodipine (Norvasc®), nifedipine (Adalat®), felodipine (Plendil®)	Block smooth muscle calcium channels causing peripheral vasodilation	HTN	Hypotension, edema, flushing, headache, light-headedness	Severe aortic stenosis and liver failure
DIURETICS					
Thiazides	hydrochlorothiazide, chlorthalidone metolazone	Reduce Na reabsorption in the DCT	HTN (drugs of choice for uncomplicated HTN)	Hypotension, hypokalemia, polyuria	Sulfa allergy, pregnancy
Loop diuretics	furosemide (Lasix®)	Blocks Na/K-ATPase in the loop of Henle	CHF, pulmonary or peripheral edema	Hypovolemia, hypokalemic metabolic alkalosis	Hypovolemia, hypokalemia
Aldosterone receptor antagonists	spironolactone, eplerenone	Antagonize aldosterone receptors	HTN, CHF, hypokalemia	Edema, hyperkalemia, gynecomastia	Renal insufficiency, hyperkalemia, pregnancy
INOTROPES					
	digoxin (Lanoxin®)	Inhibit Na/K-ATPase, leading to increased intracellular Na and Ca concentration and increased myocardial contractility. Also slows conduction through the AV node	CHF, AF	AV block, tachyarrhythmias, bradyarrhythmias, blurred or yellow vision (van Gogh syndrome), anorexia, nausea and vomiting	2nd or 3rd degree AV block, hypokalemia, WPW
ANTICOAGULANTS					
Coumarins	warfarin (Coumadin®)	Antagonizes vitamin K, leading to decreased synthesis of clotting factors II, VII, IX, and X	Atrial fibrillation, LV dysfunction, prosthetic valves	Bleeding (by far the most important side effect), paradoxical thrombosis, skin necrosis	Recent surgery or bleeding, bleeding diathesis, pregnancy
Heparins	unfractionated heparin low molecular weight heparins (LMWHs): dalteparin, enoxaparin, tinzaparin	Antithrombin III agonist, leading to decreased clotting factor activity	Acute MI; when immediate anticoagulant effect needed	Bleeding, osteoporosis, heparin- induced thrombocytopenia (less in LMWHs)	Recent surgery or bleeding, bleeding diathesis, thrombocytopenia, renal insufficiency (for LMWHs)

Table 19. Commonly Used Cardiac Therapeutics (continued)

Drug Class	Examples	Mechanism of Action	Indications	Side Effects	Contraindications
ANTIPLATELETS					
Salicylates	ASA (Aspirin®)	Irreversibly acetylates platelet COX-1, preventing thromboxane A ₂ -mediated platelet aggregation	CAD, acute MI, post-MI, post-PCI and CABG	Bleeding, GI upset, gastrointestinal ulceration, impaired renal perfusion	Active bleeding or peptic ulcer disease (PUD)
Thienopyridines	clopidogrel (Plavix®), ticlopidine (Ticlid®)	Block platelet ADP receptors	Acute MI, post-MI, post-PCI and CABG	Bleeding, thrombotic thrombocytopenic purpura, neutropenia (ticlopidine)	Active bleeding or PUD
GPIIb/IIIa inhibitors	eptifibatide, tirofiban, abciximab	Block binding of fibrinogen to Gp IIb/IIIa	Acute MI, particularly if PCI is planned	Bleeding	Recent surgery or bleeding, bleeding diathesis
THROMBOLYTICS	alteplase, reteplase, tenecteplase, streptokinase	Convert circulating plasminogen to plasmin, which lyses cross-linked fibrin	Acute STEMI	Bleeding	See Table 7, C27
NITRATES	nitroglycerin	Relax vascular smooth muscle, producing venous and arteriolar dilation	CAD, MI, CHF (isosorbide dinitrate plus hydralazine)	Headache, dizziness, weakness, postural hypotension	Concurrent use of cGMP phosphodiesterase inhibitors, angle closure glaucoma, increased ICP
LIPID LOWERING AGENTS					
Statins	atorvastatin (Lipitor®), pravastatin (Pravachol®), rosuvastatin (Crestor®), simvastatin (Zocor®), lovastatin (Meracor®)	Inhibit hydroxymethylglutaryl CoA reductase, which catalyzes the rate-limiting step in cholesterol synthesis	Dyslipidemia (1° prevention of CAD), CAD, post-MI	Myalgia, rhabdomyolysis, abdominal pain	Liver or muscle disease

Antiarrhythmics

**Figure 39. Representative Action Potential****Table 20. Antiarrhythmic* Drugs (Vaughn-Williams Classification)**

Class	Agent	Indications	Side Effects	Mechanism of Action
Ia	quinidine, procainamide, disopyramide	SVT, VT	Torsades de Pointes (all Ia), diarrhea, Lupus-like syndrome, Anti-cholinergic effects	Moderate Na channel blockade Slows phase 0 upstroke Prolongs repolarization, slowing conduction
Ib	lidocaine, mexiletine	VT	Confusion, stupor, seizures, GI upset, tremor	Mild Na channel blockade Shortens phase 3 repolarization
Ic	propafenone, flecainide, encainide	SVT, VT, AF	Exacerbation of VT (all Ic), Negative inotropy (all Ic), Bradycardia and heart block (all Ic)	Marked Na channel blockade Markedly slows phase 0 upstroke
II	propranolol, metoprolol, etc.	SVT, AF	Bronchospasm, negative inotropy, bradycardia, AV block, impotence, fatigue	Beta-blocker Decreases phase 4 depolarization
III	amiodarone**, sotalol	SVT, VT, AF, SVT, VT, AF	Photosensitivity, pulmonary toxicity, hepatotoxicity, thyroid disease, increased INR, Torsades de Pointes, bradycardia, heart block and beta-blocker side effects	Blocks K channel Prolongs phase 3 repolarization, which prolongs refractory period
IV	verapamil, diltiazem	SVT, AF	Bradycardia, AV block, Hypotension	CCB Slows phase 4 spontaneous depolarization, slowing AV node conduction

*All antiarrhythmics have potential to be proarrhythmic

**Amiodarone has class I, II, III, and IV properties

Anti-Arrhythmic Drug Classification:
 Some Block Potassium Channels
 I – Sodium CB
 II – β -Blocker
 III – Potassium CB
 IV – CCB

Table 21. Actions of Alpha and Beta Adrenergic Receptors

Target System	ALPHA RECEPTORS		BETA RECEPTORS	
	Alpha1	Alpha2	Beta1	Beta2
Cardiovascular	<ul style="list-style-type: none"> Constriction of vascular smooth muscle Constriction of skin, skeletal muscle and splanchnic vessels Increased myocardial contractility Decreased heart rate 	<ul style="list-style-type: none"> Peripherally act to modulate vessel tone Vasoconstrict and dilate; oppose Alpha 1 vasoconstrictor activity 	<ul style="list-style-type: none"> Increased myocardial contractility Accelerate SA node Accelerate ectopic pacemakers 	<ul style="list-style-type: none"> Decreased vascular smooth muscle tone
Respiratory				<ul style="list-style-type: none"> Bronchodilation
Dermal	<ul style="list-style-type: none"> Pilomotor smooth muscle contraction Apocrine constriction 			
Ocular	<ul style="list-style-type: none"> Radial muscle contraction 		<ul style="list-style-type: none"> Ciliary muscle relaxation 	
Gastrointestinal	<ul style="list-style-type: none"> Inhibition of myenteric plexus Anal sphincter contraction 			
Genitourinary	<ul style="list-style-type: none"> Pregnant uterine contraction Penile and seminal vesicle ejaculation Urinary bladder contraction 	<ul style="list-style-type: none"> Smooth muscle wall relaxation 	<ul style="list-style-type: none"> Stimulation of renal renin release 	<ul style="list-style-type: none"> Bladder wall relaxation Uterine relaxation
Metabolic	<ul style="list-style-type: none"> Stimulate gluconeogenesis and glycogenolysis at the liver 	<ul style="list-style-type: none"> Fat cell lipolysis 	<ul style="list-style-type: none"> Fat cell lipolysis Glycogenolysis 	<ul style="list-style-type: none"> Gluconeogenesis

Landmark Cardiac Trials

Trial	Reference	Results
ISCHEMIC HEART DISEASE		
4S	<i>Lancet</i> 1994; 344:1383-89	In patients with angina or previous MI and high total cholesterol, simvastatin reduced: all-cause mortality, fatal and nonfatal coronary events, need for coronary artery bypass surgery or angioplasty
A to Z: Phase Z	<i>JAMA</i> 2004; 292:1307-16	Early initiation of aggressive simvastatin regimen resulted in a trend towards reduced major cardiovascular events
ALLHAT	<i>JAMA</i> 2002; 288:2981-97	In hypertensive patients with ≥ 1 risk factors for CHD, neither amlodipine nor lisinopril reduced fatal CHD and nonfatal MI or all-cause mortality when compared with chlorthalidone (thiazide diuretics)
ASCOT-LLA	<i>Lancet</i> 2003; 361:1149-58	In hypertensive patients with risk factors for CHD and average or below-average cholesterol, atorvastatin reduced nonfatal MI, fatal CHD, fatal/nonfatal stroke, coronary events but not all-cause mortality
BHAT	<i>JAMA</i> 1982; 247:1707-14	In acute MI, propranolol reduced all-cause mortality, cardiovascular death and sudden death from atherosclerotic heart disease
CAPRIE	<i>Lancet</i> 1996; 348:1329-39	In atherosclerotic vascular disease, clopidogrel reduced the primary combined endpoint of stroke, MI or vascular death and improved peripheral arterial disease compared to aspirin
CARE	<i>NEJM</i> 1996; 335:1001-9	Pravastatin reduced MI and stroke in patients with previous MI and average cholesterol
COURAGE	<i>NEJM</i> 2008; 358:1887-98	Compared with optimal medical therapy alone, PCI + medical therapy did not reduce all-cause mortality and non-fatal MI, and it did not reduce the incidence of major cardiovascular events
CURE	<i>NEJM</i> 2001; 345:494-502	Clopidogrel plus aspirin reduced death from CV causes, non-fatal MI, or stroke but increased bleeding complications
EUROPA	<i>Lancet</i> 2003; 362:782-88	With stable CAD and no CHF, perindopril reduced cardiovascular death, MI and total mortality
FRISC II	<i>Lancet</i> 1999; 354:701-7	Dalteparin lowers risk of death, MI and the need for revascularization during the first month. These benefits are not sustained during longer term follow up
FRISC II	<i>Lancet</i> 1999; 354:708-15	Benefit of early invasive treatment in reduction of death or MI significant at 6 months
GISSI-3	<i>Lancet</i> 1994; 343:1115-22	In acute MI (<24 hours), lisinopril reduced mortality and severe ventricular dysfunction. Nitrate conferred no benefit except when combined with lisinopril
GUSTO-I	<i>NEJM</i> 1993; 329:673-82	Although there was an excess of hemorrhagic stroke with t-PA plus heparin, compared with the other regimens, the combined 30-day endpoint of death or disabling stroke was significantly lower with accelerated t-PA
HOPE	<i>NEJM</i> 2000; 342:154-60	In high-risk patients without low LVEF or CHF, ramipril reduced rates of death, MI, stroke, revascularization, new diagnosis of diabetes and complications due to diabetes. Vitamin E had no effect on outcomes.
HPS	<i>Lancet</i> 2002; 360:7-22	In high-risk patients with various cholesterol values, simvastatin reduced all-cause mortality, coronary deaths and major vascular events
ISIS-2	<i>Lancet</i> 1988; 2:349-60	Early therapy with SK and ASA in patients with MI individually and in combination significantly reduced all-cause mortality and in combination demonstrated additive effect
ISIS-4	<i>Lancet</i> 1995; 345:669-85	In patients with suspected or definite acute MI, early treatment with captopril reduced all-cause mortality at 35 days and during long-term follow up
LIPID	<i>NEJM</i> 1998; 339:1349-57	Pravastatin reduced both mortality due to CHD and overall mortality and had benefit for patients with unstable angina
OASIS-5	<i>NEJM</i> 2006; 354:1464-76	Compared to enoxaparin, fondaparinux reduced mortality rates, major bleeds at 9 and MI at 30d and 180d
OPTIMAAL	<i>Lancet</i> 2002; 360:752-60	Losartan 50 mg daily conferred no benefit in comparison with captopril
PROVE IT – TIMI 22	<i>NEJM</i> 2004; 350:1495-1504	In patients hospitalized for ACS, high-dose atorvastatin reduced all-cause mortality, MI, unstable angina, revascularization and stroke compared with pravastatin
SYNTAX	<i>NEJM</i> 2008; 360:961-972	CABG has lower rate of major cardiac or cerebrovascular events. The rate of stroke was increased with CABG, whereas the rate of repeat revascularization was increased with PCI
TNT	<i>NEJM</i> 2005; 352:1425-35	Lipid-lowering therapy with atorvastatin 80 mg/day in patients with stable CHD provides clinical benefit beyond atorvastatin 10 mg/day
WOSCOPS	<i>NEJM</i> 1995; 333:1301-7	Pravastatin reduced nonfatal MI or death from CHD and need for myocardial revascularization procedures in patients with hypercholesterolemia and no MI

Trial	Reference	Results
HEART FAILURE		
AIRE	<i>Lancet</i> 1993; 342:821-8	Ramipril commenced 3-10 days after MI and continued for a mean 15-month period significantly reduced all-cause mortality in patients with non-severe CHF
CHARM	<i>Lancet</i> 2003; 362:759-66	Candesartan reduced overall mortality, cardiovascular death and CHF hospitalizations
CIBIS II	<i>Lancet</i> 1999; 353:9-13	Bisoprolol reduced all-cause mortality, cardiovascular death, all-cause hospitalization and CHF hospitalization
COMET	<i>Lancet</i> 2003; 362:7-13	Carvedilol was associated with a reduction in all cause mortality compared with metoprolol
CONSENSUS	<i>NEJM</i> 1987; 316:1429-35	Enalapril reduced all-cause mortality, death due to progression of heart failure
COPERNICUS	<i>NEJM</i> 2001; 344:1651-8	Carvedilol in addition to standard treatment significantly reduced the risk of death or hospitalization in patients with severe CHF
I-PRESERVE	<i>NEJM</i> 2008; 359:2456-2467	In patients with CHF and normal LVEF, treatment with ARB (irbesartan) did not improve mortality or cardiovascular morbidity compared to placebo
MERIT-HF	<i>Lancet</i> 1999; 353:2001-7	Metoprolol CR/XL daily in addition to optimum standard therapy improved survival in clinically stable patients, equating to prevention of 1 death per 27 patients treated per year
RALES	<i>NEJM</i> 1999; 341:709-17	In severe CHF and LVEF <35%, spironolactone reduced all-cause mortality, sudden death and death due to progression of heart failure
SAVE	<i>NEJM</i> 1992; 327:669-77	Patients with LV dysfunction post-MI, long-term captopril over 3.5y reduced the risk of death due to cardiovascular causes, recurrent MI, development of severe CHF and CHF hospitalization
SCD-HeFT	<i>NEJM</i> 2005; 352:225-237	In mild-to-moderate CHF, shock-only ICD significantly reduces risk of death. Amiodarone had no benefit compared with placebo in treating patients with mild-to-moderate CHF
SOLVD	<i>NEJM</i> 1991; 325:293-302	In stable chronic CHF with decreased LVEF (<0.35), long-term enalapril reduced death due to all causes and death or hospitalization due to CHF
TRACE	<i>NEJM</i> 1995; 333:1670-6	In patients with LV dysfunction post-MI, long-term trandolapril reduced the risk of death or progression to severe CHF and reduced risk of sudden death
V-HeFT II	<i>NEJM</i> 1991; 325:303-10	In chronic CHF, enalapril reduced mortality more than hydralazine-isosorbide for at least 2y. Treatment with either enalapril or hydralazine-isosorbide increased LVEF
DIABETES		
CARDS	<i>Lancet</i> 2004; 264:685-96	Atorvastatin reduces the risk of cardiovascular events in patients with type 2 diabetes
ONTARGET	<i>NEJM</i> 2008; 358:1547-59	In patients with vascular disease or diabetes without CHF, telmisartan is equally as effective as ramipril, with telmisartan causing a reduced risk of cough and angioedema, and an increased risk of hypotensive symptoms. Combination therapy offers no advantage
ARRHYTHMIA		
AFFIRM	<i>NEJM</i> 2002; 347:1825-33	No significant difference in mortality rates between rate or rhythm control
CAST	<i>NEJM</i> 1989; 321:406-12	Encainide or flecainide started ~15d after MI caused excessive mortality risk, excessive risk of death from arrhythmia in asymptomatic or mildly symptomatic ventricular arrhythmias after MI
HYPERTENSION		
HYVET	<i>NEJM</i> 2008; 358:1887-98	In hypertensive patients >80 y, treatment with indapamide, with or without perindopril, showed a trend towards reduced relative risk of fatal or non-fatal stroke
UKHDS (UKPDS)	<i>BMJ</i> 1998; 317:703-13	Hypertensive patients with DM and tight BP control at <150/85 mmHg by use of ACEi or beta-blocker reduced risk of diabetic complications and death related to diabetes and reduced risk of end-organ damage
VALUE	<i>Lancet</i> 2004; 363:2022-2031	Valsartan group had higher incidence of MI than amlodipine group, whereas amlodipine had a higher incidence of new onset diabetes
MISCELLANEOUS		
JUPITER	<i>NEJM</i> 2008; 359:2195-2207	With low to normal LDL-C and elevated hsCRP, treatment with rosuvastatin significantly reduced major cardiovascular events. NNT with rosuvastatin for 2 years to prevent one primary endpoint = 95
WHI	<i>JAMA</i> 2002; 288:321-333	Estrogen plus progestin therapy is associated with increased risks of cardiovascular disease and breast cancer but decreased risks of hip fracture and colorectal cancer in postmenopausal women

General Principles

Drug Nomenclature

- chemical name: describes the chemical structure; the same in all countries
 - e.g. N (4-hydroxyphenyl) acetamide is acetaminophen
- drug company code: a number; usually for drugs that are not yet marketed
- non-proprietary (generic) name: shortened form of chemical name; listed in pharmacopoeia
 - e.g. acetaminophen
- proprietary (trade) name: the brand name or registered trademark
 - e.g. Tylenol®
- street name: slang term used for a drug of abuse

Phases of Clinical Testing

- phase I: first administration to healthy human volunteers, following animal studies; to determine pharmacokinetics and pharmacodynamics
- phase II: first administration to patients, small studies; to determine therapeutic efficacy, dose range, pharmacokinetics, pharmacodynamics
- phase III: large sample, often double-blind RCT; to compare a new drug to placebo or standard of care, establish safety and efficacy
- phase IV: post-marketing surveillance, wide distribution; to determine rare adverse reactions, effects of long-term use, determine ideal dosing

Drug Administration and Site of Action

- choice of route of administration depends on
 - properties of the drug
 - local and systemic effects (limiting action or adverse events)
 - desired onset and/or duration of action
 - patient characteristics

Table 1. Routes of Drug Administration

Route	Advantage	Disadvantage
Oral (PO)	Convenient, easy to administer Large surface area for absorption Inexpensive relative to parenteral administration	Drug metabolism by GI secretions Incomplete absorption Hepatic first-pass effect Potential GI irritation
Buccal Sublingual (SL)	Rapid onset of action No hepatic first-pass effect	Must be lipid soluble Must be non-irritating Short duration of action
Rectal (PR)	Almost no hepatic first-pass effect Convenient if patient is NPO, vomiting or unconscious	Inconvenient Irritation at site of application Erratic absorption
Intravenous (IV)	Direct to systemic circulation No hepatic first-pass effect Slow infusion or rapid onset of action Easy to titrate dose	Requires IV access, aseptic technique Hard to remove once administered Vascular injury, extravasation Expensive Risk of infection, bleeding
Intra-arterial	Direct to specific organs (heart, brain) No hepatic first-pass effect	Risk of infection, bleeding, vascular complications
Intramuscular (IM)	Depot storage if oil-based = slow release of drug Aqueous solution = rapid onset of action	Pain at site of injection
Subcutaneous (SC)	Non-irritating drugs, small volumes Constant, even absorption Alternative to IV	Pain at site of injection Smaller volumes than IM May have tissue damage from multiple injections
Intrathecal	Direct into cerebrospinal fluid (CSF) Bypass BBB and blood-CSF barrier	Infection Possibility of brain herniation and coning

At the time of drug launch, only data from phases I-III are available; thus true effectiveness (in contrast to efficacy) and safety may be unknown, because real-world patients and usage patterns often do not reflect premarket phase.

Common Latin Abbreviations

q	each, every
od/bid/tid/qid	once/twice/three/four times a day
hs	at bedtime
ac/pcc/cc	before/after/with meals
prn	as necessary
gtt	drops
ung	ointment
ud	as directed
od/os/ou	right/left/each eye
ad/as/au	right/left/each ear

Table 1. Routes of Drug Administration (continued)

Route	Advantage	Disadvantage
Inhalation	Immediate action in lungs Rapid delivery to blood Local or systemic action No hepatic first-pass effect	Must be a gas, vapour or aerosol
Topical	Easy to administer Localized Limited systemic absorption	Effects are mainly limited to site of application
Transdermal	Drug absorption through intact skin Rapid onset of action No hepatic first-pass effect	Irritation at site of application Delayed onset of action Hydrophilic drugs are not easily absorbed
Others: Intraperitoneal, Intra-articular	Local effect	Risk of infection

Overview of Drug Disposition

Pharmacology = Pharmacokinetics + Pharmacodynamics

Pharmacokinetics

- the study of “what the body does to a drug;” the fate of a drug in the body
- subdivided into ADME: absorption, distribution, metabolism and elimination

Pharmacodynamics

- the study of “what a drug does to the body;” the interaction of a drug with its receptor and the resultant effect
- includes dose-response relationship, drug-receptor binding

Pharmacokinetics (ADME)

- definition: relationship between drug administration, time-course of distribution, and concentration achieved in the body (i.e. the manner in which the body handles a drug)
- examines rate and extent at which drug level concentrations change in the body by observing:
 - input processes = absorption
 - output processes responsible for drug delivery and removal from the body = distribution, metabolism, elimination

Absorption

- definition: movement of the drug from the site of administration into plasma
- important for the main routes of administration, except IV

Mechanisms of Drug Absorption

- most drugs are absorbed into the systemic circulation via passive diffusion
- other mechanisms: active transport, facilitated diffusion, pinocytosis/phagocytosis

Factors Affecting the Rate and Extent of Drug Absorption

- partition coefficient of a drug ($P_{\text{oil/water}}$), i.e. its relative solubility in oil (lipid) vs. water
 - drugs with high lipid solubility can rapidly diffuse across a cell membrane (e.g. anaesthetics are very lipid soluble and thus have a rapid onset of action)
- local blood flow at the site of administration (e.g. sublingual vessels provide significant blood flow and thus rapid absorption)
- molecular size (e.g. small molecular weight drugs absorb faster)
- pH and drug ionization
 - drugs are usually weak acids (e.g. acetylsalicylic acid) or weak bases (e.g. ketoconazole) and thus have both ionized and non-ionized forms
 - pH and pK_a determine the ratio of ionized:non-ionized ratio (using the Henderson-Hasselbach equation)
 - non-ionized forms cross cell membranes much faster than ionized (charged) forms
- total surface area for absorption
 - the small intestine has villi, which increase the surface area for absorption, making it the primary site of absorption for most oral drugs

Partition Coefficient (P)

- The ratio of a drug's solubility in lipid as compared to water
- More relevant when thought of in terms of a drug's solubility in membrane as compared to extracellular fluid
- A large P means that a drug is highly soluble in lipid and will thus cross membranes easily

Drug Ionization and the Henderson-Hasselbach Equation

Ionization reaction for a weak acid:
 $HA \rightleftharpoons A^- + H^+$; $pK_a = pH + \log [HA/A^-]$
 (Henderson-Hasselbach equation)

For a weak acid of $pK_a = 4.4$,
 at a gastric pH of 1.4,
 non-ionized:ionized = $HA:A^- = 1:0.001$

Thus, the drug is mainly non-ionized and diffuses across membrane

Ionization reaction for a weak base:
 $BH^+ \rightleftharpoons B + H^+$; $pK_a = pH + \log [BH^+/B]$

The amount of drug that reaches the systemic circulation (bioavailability) is highly dependent on absorption and the first-pass effect. Properties of the drug, route of administration and patient factors should be considered to ensure clinical effectiveness.

Bioavailability (F)

- definition: drug fraction of administered dose that reaches systemic circulation in an unchanged state after administration
- factors affecting bioavailability:
 - drug absorption, metabolism in the gut wall, and hepatic first-pass effect
- IV dose have 100% bioavailability ($F = 1$)
- drugs with a low bioavailability may require a much a much larger oral dose when compared to the intravenous dose (e.g. beta-blockers: metoprolol 5 mg IV vs. metoprolol 50 mg PO)

Hepatic First-Pass Effect

- definition: drug metabolism by the liver following absorption, but before it reaches systemic circulation
- occurs with PO administration of a drug: GI tract (absorption) → portal vein in liver (first-pass metabolism) → systemic circulation; significant first-pass effect can drastically reduce a drug's bioavailability
- occurs to much lesser extent with PR administration, because drug absorbed in colon bypasses the portal system: colon (absorption) → internal pudendal veins → IVC → systemic circulation
- drugs with a high hepatic first-pass effect (hepatic extraction) include:
 - levodopa, morphine, propranolol, lidocaine, organic nitrates
- drugs with low hepatic extraction (little or no first-pass effect) include:
 - diazepam, digoxin, phenytoin, warfarin

Efflux Pump

- P-glycoprotein (Pgp) is a protein in the GI tract and renal epithelium that acts as a multidrug efflux pump involved in the transport of drugs out of cells
 - i.e. reduced intestinal absorption and enhanced renal elimination of certain drugs
- examples of Pgp substrates:
 - digoxin, etoposide, paclitaxel, tacrolimus
- some drugs (e.g. macrolide antibiotics) inhibit Pgp and can increase absorption of Pgp substrates and reduce their renal elimination
- some tumours overexpress Pgp leading to multi-drug resistance to chemotherapy agents

Distribution

- definition: process by which drugs move between different body compartments and to the site of action
- major body fluid compartments: plasma, interstitial fluid, intracellular fluid, transcellular fluid (e.g. CSF, peritoneal, pleural)
- tissue compartments: fat, brain

Factors Affecting the Rate and Extent of Drug Distribution

- physicochemical properties of the drug (e.g. partition coefficient)
- pH of fluid
- plasma protein binding
- binding within compartments
- cardiac output
- regional blood flow
- percentage body fat

Volume of Distribution (V_d)

- maximum "actual V_d " = total body water (40 L for average adult) (see Figure 1)
- V_d : the apparent volume of fluid into which a drug dissolves
 - relates amount of drug in the body to the plasma concentration
 - a calculated value that does not correspond to an anatomical space (when calculated, V_d can exceed a person's total body water or 40 L)
 - the value takes into account drug distribution into tissues and protein binding
 - volume of distribution of plasma-protein bound drugs can be altered by liver and kidney disease
 - $V_d = \text{amount of drug in body} / \text{plasma drug concentration}$
- example: amiodarone distributes into total body water (TBW = actual $V_d = 40$ L), but it also concentrates in fat tissues giving instead an apparent V_d of 400 L; i.e. to achieve a given plasma concentration of amiodarone, we dose as if the drug distributes into 400 L of body fluid

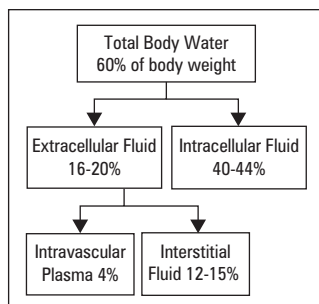

Figure 1. Distribution of Total Body Water (TBW)

Principles of Protein Binding

- drug molecules in the blood exist in two forms:
 1. bound to plasma proteins
 - ♦ acidic drugs bind to albumin
 - ♦ basic drugs bind to α_1 -acid glycoprotein
 2. free or unbound
 - ♦ only free drug can leave the circulation to distribute into tissues and exert an effect; free drug is subject to metabolism and elimination

- in plasma, the fractions of free and bound drugs exist in equilibrium, i.e. as free drug leaves the circulation, more drug unbinds to equilibrate with the portion that is left
- the fraction of drug that is bound is determined by
 - drug concentration, drug affinity for protein binding site, and number of binding sites or protein concentration
- saturation of binding sites may result in a large increase in free drug concentration, potentially leading to toxicity
- in hypoalbuminemia (liver failure or nephrotic syndrome), the dose of some highly bound drugs must be lowered to avoid toxicity
- multiple drugs and endogenous substances can compete for the same protein binding sites, leading to increased free drug concentration but it is rarely of clinical significance
 - e.g. ASA displaces highly protein bound acidic drugs such as phenytoin, thus possibly increasing the risk of toxicity; sulfonamide displaces bilirubin from protein binding sites, which could potentially lead to jaundice and kernicterus in neonates
- usually only highly protein bound (>90%) drugs are involved in drug interactions due to competitive binding; however, plasma protein binding interactions are rarely of clinical significance

Depots

- a body compartment (i.e. a type of tissue) where drug molecules tend to be stored and released slowly over a long period of time
- fat is a depot for very lipid soluble drugs (e.g. diazepam)
- some oil-based medications are injected IM for slow release (e.g. depot medroxyprogesterone acetate q3mo; depot risperidone q2wks)

Barriers (relative)

- body structures that limit or prevent diffusion of drug molecules
 - e.g. the placenta or blood brain barrier (BBB; a barrier composed of tight junctions between capillary endothelial cells and astrocytes)
- many of these barriers result, in part, from the activity of multidrug efflux pumps (e.g. Pgp) which serve as a natural defense mechanism against drugs and xenobiotics
- need to consider dosing route if drugs are meant to cross these barriers

Metabolism (Biotransformation)

- definition: chemical transformation of a drug *in vivo*
- sites of biotransformation: liver (main), GI tract, lung, plasma, kidney
- goal is to make compounds more hydrophilic to enhance renal elimination
- as a result of the process of biotransformation:
 - a pro-drug may be **activated** to an active drug (e.g. tamoxifen to endoxifen)
 - a drug may be **changed** to another active metabolite (e.g. diazepam to oxazepam)
 - a drug may be **changed** to a toxic metabolite (e.g. meperidine to normeperidine)
 - a drug may be **inactivated** (e.g. procaine to PABA)

Drug Metabolizing Pathways

- phase I (P450) reactions
 - small molecular changes introduce or unmask polar chemical groups on a parent compound to increase its water solubility (e.g. oxidation-reduction, hydrolysis, hydroxylation); the change in the partition coefficient is typically minimal (demethylation, deamination, hydroxylation) compared to phase II, and often phase I places a polar 'handle' on a lipophilic drug to allow for phase II
 - mediated by cytochrome P450 enzymes found in the endoplasmic reticulum or cell cytoplasm
 - product of the reaction can be excreted or undergo further phase II reactions
- phase II (conjugation) reactions
 - conjugation with large polar endogenous substrates (e.g. glucuronidation, glutathione conjugation, sulfation)
 - dramatically increases water solubility and renal elimination

Factors Affecting Drug Biotransformation

- **genetic polymorphism** of metabolizing enzymes
 - individuals may metabolize drugs faster or slower depending on their genotype, resulting in poor, intermediate, extensive or ultrarapid metabolizers
 - may lead to toxicity or ineffectiveness of a drug at a normal dose (e.g. tamoxifen and codeine are prodrugs activated by 2D6 (nonfunctional alleles reduce effectiveness), while warfarin metabolized by 2C9 (nonfunctional alleles lead to lower dose requirements))

Special consideration must be given in dosing patients in hypoalbuminemic states to prevent drug toxicity. Highly protein-bound drugs will exert a greater effect in these patients than in healthy individuals because of higher levels of free drug.

Examples of highly protein-binding drugs: warfarin, digoxin, diazepam, furosemide, amitriptyline.

Main Factors Governing Penetration of Blood Brain Barrier (BBB)

1. Small molecular size (<500 Daltons)
2. High lipid solubility
3. Active transport mechanisms (e.g. Pgp multidrug efflux pump)

Many Drugs Cross BBB. Examples:

- General anesthetics
- Alcohol
- Nicotine
- Caffeine
- L-dopa
- Narcotics
- Psychotropic medications

Cytochrome P450 System

The P450 enzymes are a superfamily of heme proteins that are grouped into families and subfamilies according to their amino acid sequence. These proteins are responsible for the metabolism of drugs, chemicals and other substances.

Nomenclature: CYP3A4
"CYP" = cytochrome P450 protein

1st number = family
letter = subfamily
2nd number = isoform

The CYP1, CYP2, and CYP3 families metabolize most drugs in humans. The most important isoforms are CYP3A4 and CYP2D6; therefore, anticipate drug interactions if prescribing drugs using these enzymes.

Some Common Examples of P450 Inhibitors and Inducers

P450 inhibitors "MINCE"

Metronidazole
Isoniazid, Indinavir
Naringin or bergamottin (bioflavonoid in grapefruit)
Ciprofloxacin, Cimetidine
Erythromycin (macrolides)

P450 inducers

Phenytoin
Phenobarbital
Rifampin
Smoking

Note: Several medications are known to affect P450s. The above list is not exhaustive.

The very young and the very old are very sensitive to the actions of drugs.

- **enzyme inhibition** may sometimes be due to other drugs
 - e.g. CYP3A4 inhibition leads to an increased concentration of the substrate drug
 - erythromycin, ketoconazole and indinavir inhibit CYP3A4 and predispose a patient to drug toxicity from other drugs metabolized by it
 - grapefruit juice inhibits gut CYP3A4 and effectively increases a substrate's bioavailability
- **enzyme induction**
 - certain medications enhance gene transcription leading to an increase in the activity of a metabolizing enzyme
 - a single drug may stimulate multiple P450 isoenzymes simultaneously
 - a drug may induce its own metabolism (e.g. carbamazepine) or that of other drugs (e.g. phenobarbital can induce the metabolism of OCP and bilirubin) by inducing the P450 enzyme system
 - other potent enzyme inducers: phenytoin, dexamethasone
- **liver dysfunction** caused by disease (such as hepatitis, alcoholic liver, biliary cirrhosis or hepatocellular carcinoma) may decrease drug metabolism, but this may not be clinically significant due to the liver's reserve capacity
- **renal disease** often results in decreased drug clearance if it is cleared by the kidneys
- **extremes of age** (neonates or elderly) have reduced biotransformation capacity, and doses should be adjusted accordingly
- **nutrition**
 - insufficient protein and fatty acid intake decrease P450 biotransformation
 - vitamin and mineral deficiencies may also impact metabolizing enzymes
- **alcohol**: while acute alcohol ingestion inhibits 2E1, chronic consumption can induce this same enzyme and increase the risk of hepatocellular damage from acetaminophen by increasing the generation of acetaminophen's toxic metabolite
- **smoking** can induce 1A2, thus increasing the metabolism of some drugs (e.g. smokers may require higher doses of theophylline, which is metabolized by 1A2)

Elimination

- definition: removal of drug from the body

Routes of Drug Elimination

- kidney (main organ of elimination)
 - two mechanisms for renal elimination
 1. glomerular filtration
 - a passive process, so that only the free drug fraction can be filtered
 - drug filtration rate depends on GFR, degree of protein binding of drug, and size of drug
 2. tubular secretion
 - an active process that is saturable, allowing both protein-bound and free drug fractions to be excreted
 - two distinct transport mechanisms for weak acids (e.g. penicillin, salicylic acid, probenecid, chlorothiazide) and weak bases (e.g. quinine, quaternary ammonium compounds such as choline)
 - drugs may competitively block mutual secretion if both use the same secretion system (e.g. probenecid can be used to reduce the excretion of penicillin, thereby prolonging the half-life and thus the effect of the antibiotic)
 - tubular reabsorption: drugs can be passively reabsorbed back to the systemic circulation, countering elimination mechanisms
 - elimination rate depends on renal function, which decreases with age and is affected by many disease states; renal function is assessed clinically using serum creatinine (Cr) levels
 - thus, in those with renal impairment, dosage adjustments may be required for medications affected by renal elimination
- stool
 - some drugs and metabolites are actively excreted in the bile (e.g. corticosteroids) or directly into the intestinal tract from systemic circulation
 - enterohepatic circulation
 - ♦ counteracts stool elimination, and thus can substantially prolong the drug's duration in the body
 - ♦ some glucuronic acid conjugates that are excreted in the bile will be hydrolyzed in the intestines by bacteria; this results in the drug being converted back to its original form and allows for systemic reabsorption
- lungs
 - elimination of anesthetic gases and vapours by exhalation
- saliva
 - saliva concentrations of some drugs parallel their plasma levels (e.g. rifampin)

Avoid toxicity from drug or metabolite accumulation by adjusting a drug's dosage according to the elimination characteristics of the patient (e.g. in renal impairment).

The Cockcroft-Gault Equation can estimate creatinine clearance (CrCl) in adults 20 years of age and older:

- For males

$$\text{CrCl (mL/min)} = \frac{[(140 - \text{age in yrs}) \times \text{Weight (kg)}]}{\text{serum Cr (}\mu\text{mol/L)}} \times 1.2$$
- For females, multiply above equation x 0.85
- Only applies when renal function is at steady state

Pharmacokinetics Calculations

- definition: the quantitative description of the rates of the various steps of drug disposition, i.e. how drugs move through the body
- the pharmacokinetic principles of ADME (absorption, distribution, metabolism and elimination) can be graphically represented on the concentration vs. time graph (see Figure 2)

Time-Course of Drug Action

- many kinetic parameters are measured using IV dosing, such that absorption is zero and distribution for most drugs is rapid; thus elimination is the main process being measured
 - the concentration axis is converted to a \log_{10} concentration to allow for easier mathematical calculations (see Figure 3)

Half-Life ($t_{1/2}$)

- definition: time taken for the serum drug level to fall to 50% during elimination
- for drugs with first order kinetics, takes five half-lives to reach steady state with repeated dosing, or for drug elimination once dosing is stopped
- only applies when drug exhibits first order kinetics
- see sidebar for calculation

# of Half Lives	1	2	3	3.3	4	5
Concentration	50%	75%	87.5%	90%	93.8%	96.9%

Steady State

- the concentration at which the same amount of drug entering the system is eliminated from the system
- time is important for therapeutic monitoring since drug levels are reliable only when the drug has reached steady state (see Figure 4)
- special situations
 - use a loading dose for drugs with a long half-life and when there is clinical need to rapidly achieve therapeutic levels (e.g. amiodarone, digoxin, phenytoin)
 - use continuous infusion for drugs with a very short half-life and when there is need for a long-term effect and multiple or frequently repeated doses are too inconvenient (e.g. nitroprusside, insulin, unfractionated heparin)

Clearance (CL)

- a quantitative measurement of the rate of removal of a substance from the body
- relates the rate of elimination to the plasma concentration
- clearance = body fluid volume from which a substance is removed per unit time
- consider: clearance from a specific part of the body, and total body clearance
- CL = rate of elimination of drug/plasma drug concentration

Elimination Kinetics (see Figure 5)

- first-order kinetics (most common type)
 - linear and predictable relationship that leads to a constant fraction of drug eliminated per unit time
 - the amount of drug eliminated is based on the concentration of drug present
- zero-order kinetics (less common, associated with toxicities, e.g. alcohol)
 - non-linear kinetics that leads to a constant rate of drug eliminated regardless of concentration
 - clearance slows as drug concentration rises
 - some drugs can follow first-order kinetics until elimination is saturated (usually at large doses) at which point the clearance decreases
 - some drugs follow zero-order kinetics at therapeutic levels (e.g. phenytoin)

Table 2. Loading vs. Maintenance Dosing

Loading Dose	Maintenance Dose
Use when you need an IMMEDIATE effect	Consider either: after a loading dose OR beginning with maintenance doses
Often parenteral medication	Steady-state levels achieved after ~5 half lives
Rational: give large dose of medication to "fill up" the volume of distribution	Can be given as either a continuous infusion (relatively rare, short half-life drug) OR much more commonly as intermittent doses

Principles of Pharmacokinetics

V_d = amount of drug in the body/
plasma drug concentration

CL = rate of elimination of drug/plasma
drug concentration

Half-life ($t_{1/2}$) = $0.7 \times V_d / CL$

For most drugs, it takes 5 half-lives to reach steady state with repeated dosing or to eliminate a drug once dosing is stopped.

Figure 2. Time Course of Drug Action

Figure 3. Log Concentration vs. Time Graph (IV bolus dose)

Figure 4. Steady State of a Drug

Figure 5. First and Zero Order Kinetics. In first order kinetics (solid line), a constant fraction of the drug is eliminated per unit time; in zero order kinetics (dashed line), a constant amount of the drug is eliminated per unit time.

For unit conversion factors, please see Appendix: Common Unit Conversions.

Pharmacodynamics

Dose-Response Relationship

- effectiveness and potency are two important pharmacodynamic characteristics of a drug that can be quantified using dose-response curves
- with gradual dose-response relationships, the response of the drug reflects the number of receptors that are effectively occupied

Effectiveness

- a measure of a drug's ability to elicit a concentration-independent effect at its receptor
- measured as E_{max} = the maximal **response** that a drug can elicit (see Figure 6)
- reflects drug response under ideal circumstances (e.g. controlled clinical trial)
- e.g. if Drug A causes a greater maximum intensity of response than Drug B regardless of dose, then Drug A is more efficacious than Drug B

Potency

- a measure of the effect produced by a certain drug concentration
- measured as ED_{50} (or EC_{50}) = the **effective concentration** of a drug needed to produce 50% of the maximal possible effect (see Figure 6)
- can compare the ED_{50} of two or more drugs that have parallel log dose-response curves
- the drug that reaches its ED_{50} at the lower dose is the more potent
- if the potency of a drug is low, this may be overcome by increasing the dose of the drug (e.g. 30 mg vs. 15 mg); this is not problematic provided that the higher dose not cause adverse effects

Effectiveness versus Potency

- Effectiveness measures a drug's maximal effect and is independent of concentration.
- Potency measures a drug's concentration needed to produce a certain effect.

Figure 6. Log Dose-Response Curve Illustrating Effectiveness and Potency

Effects of Drugs on Receptors

- drugs that act on specific receptors can be broadly classified as agonists or antagonists (see Figure 7)

Agonists

- drugs that mimic endogenous ligands and exert an effect
- have two main properties
 - affinity: the ability of the agonist to bind to the receptor (e.g. the β_2 -agonist salbutamol has greater affinity for β_2 -receptors than β_1 -receptors)
 - efficacy: the ability to cause a response via the receptor interaction (e.g. binding of salbutamol to β_2 -receptors results in smooth muscle relaxation)
- full agonists: can elicit a maximal effect at a receptor
- partial agonists: can only elicit a partial effect, no matter how high the concentration
 - e.g. reduced efficacy compared to full agonists

Antagonists

- drugs that have affinity (can bind to a receptor), but no efficacy
- these are drugs that block the action of an agonist or of an endogenous ligand
- chemical antagonism:** direct chemical interaction between agonist and antagonist that prevents agonist binding to receptor
 - e.g. chelating agents for removal of heavy metals

- **functional antagonism:** interaction of two agonists that act independently at different receptors but have opposite physiological effects
 - e.g. acetylcholine at the muscarinic receptor decreases HR, constricts pupils, and stimulates intestinal motility; whereas epinephrine at the adrenergic receptor increases HR, dilates pupils, and decreases intestinal motility
- **reversible competitive antagonism** (most common in clinical practice, see Figure 8)
 - antagonist reversibly binds to the same receptor as the agonist, thus displacing it (e.g. naloxone is an antagonist to morphine or heroin)
- **irreversible competitive antagonism** (see Figure 9)
 - antagonist irreversibly binds to the same receptor as the agonist, blocking it from binding (e.g. acetylsalicylic acid irreversibly binds cyclo-oxygenase in platelets)
- **non-competitive antagonism** (see Figure 9)
 - antagonist binds to an alternate site separate but near to the agonist receptor, producing allosteric effects that change the ability of the agonist to bind (e.g. organophosphates irreversibly bind acetylcholinesterase)

Figure 8. The Log Dose-Response Curve for Competitive Reversible Antagonism

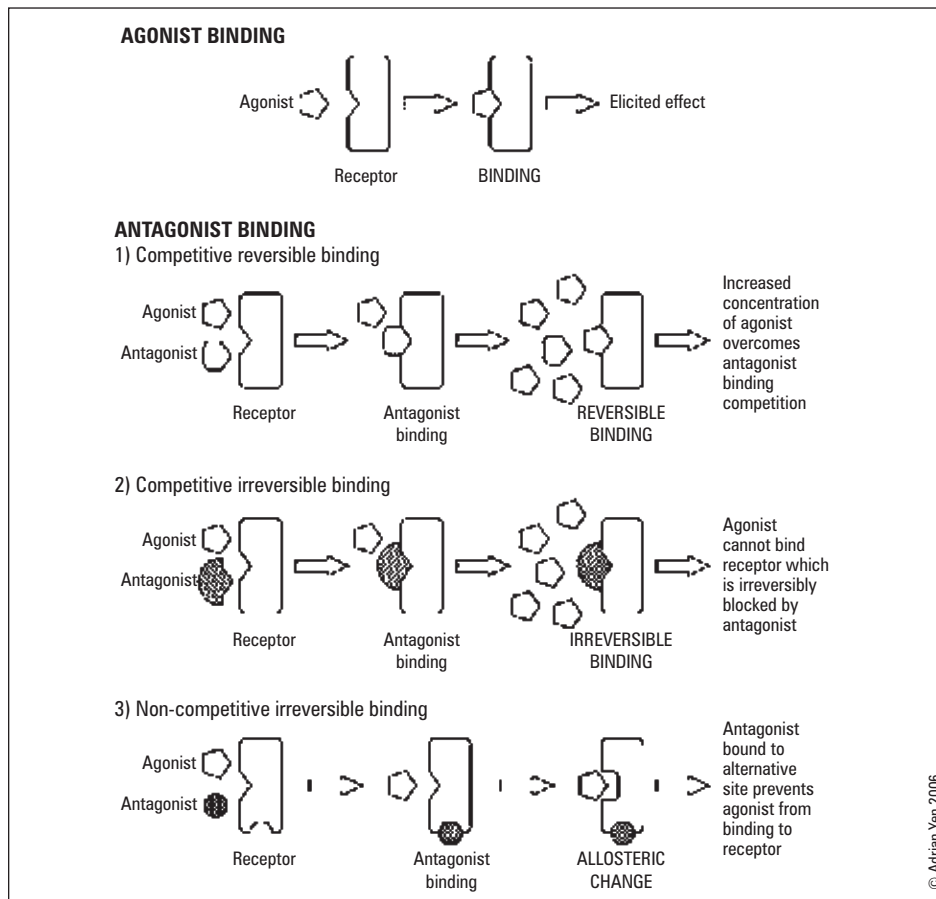

Figure 7. Mechanism of Agonists and Antagonists

Figure 9. The Log Dose-Response Curve for Irreversible Antagonism

Effectiveness and Safety

Effectiveness

- ED_{50} (Effective Dose – 50%): the dose of a drug needed to cause a therapeutic effect in 50% of a test population of subjects

Safety

- LD_{50} (Lethal Dose – 50%): the dose of a drug needed to cause death in 50% of a test population of subjects (usually rodents)
- TD_{50} (Toxic Dose – 50%): the dose needed to cause a harmful effect in 50% of a test population of subjects

The two most clinically relevant properties of any drug are effectiveness and safety.

Drugs with a narrow TI have a high likelihood of causing toxicity and need close therapeutic monitoring.

Therapeutic Index (TI)

- defined as TD_{50}/ED_{50} (see Figure 10)
- reflects the “margin of safety” for a drug – the likelihood of a high dose causing serious toxicity or death
- the larger the TI, the safer a drug (e.g. amoxicillin has a wide TI, thus therapeutic monitoring is not needed, whereas warfarin has a narrow TI and must have accurate therapeutic monitoring)
- factors that can change the ED_{50} , LD_{50} or TD_{50}
 - presence of interacting drugs
 - changes in drug absorption, distribution, metabolism, elimination

Figure 10. ED_{50} , TD_{50} , and the Therapeutic Index (TI)

Therapeutic Drug Monitoring (TDM)

- definition: using serum drug concentration data to optimize drug therapy (e.g. dose adjustment, monitor compliance)
 - serum drug samples are usually taken when the drug has reached steady state (e.g. trough level – the lowest level before the next dose), and thus, before the next dose
- TDM can serve to monitor for side effects (e.g. vancomycin trough levels) and for desired effect (e.g. INR when on warfarin therapy)
- TDM is often used for drugs that have
 - narrow therapeutic index (TI)
 - unpredictable dose-response relationship
 - significant consequences associated with therapeutic failure or toxicity
 - wide inter-patient pharmacokinetic variability

Adverse Drug Reactions (ADRs)

- classification of adverse drug reactions
 - type A: undesirable normal/augmented responses to the drug (>80% of all ADRs)
 - type B: reaction unrelated to the known pharmacological actions of the drug
- additional adverse drug reaction categories
 - type C (chronic effects), type D (delayed effects), type E (end-of-treatment effects), and type F (failure of therapy)

Table 3. Comparison of characteristics of type A and type B reactions

Type A	Type B
Predictable extension of drug's pharmacologic effect	Unpredictable
Usually dose dependent	Rarely dose dependent
Low mortality (except heroin overdose)	High mortality (some exceptions)
Responds to dose reduction	Responds to drug withdrawal

Examples of drugs whose levels need to be monitored: warfarin (via INR levels), digoxin, lithium, and many others.

In Canada, an estimated 1.6% of patients admitted to hospitals experience a serious adverse drug reaction. Furthermore, up to 24% of hospitalizations are drug related, of which 35.5% are adverse drug reactions.

Type A Drug Reactions

- extension of a drug's pharmacological effects: excessive but characteristic pharmacological effect from usual dose of a drug (e.g. beta-blockers causing bradycardia; acetaminophen causing hepatitis)
- overdose/toxicity: exaggerated but characteristic pharmacological effect from SUPRA-therapeutic dose
- teratogen: drug may produce developmental defects in fetus (not always in a dose-related manner)

Type B Drug Reactions

- idiosyncratic: uncharacteristic response to drug, unrelated to pharmacology (e.g. sulfa-containing medications causing toxic epidermal necrolysis)
- pseudoallergenic: mimics immune-mediated reaction
- allergic/immune-mediated: does not occur on first exposure (up to 7 d), immediate with subsequent exposure, may occur with low doses, often resolves within 3-4 days of discontinuation

Sulfa-Containing Medications

- Sulfamethoxazole
- Sulfasalazine
- Dapsone

Approach to Suspected ADRs

- history and physical examination: signs and symptoms of the reaction (e.g. rash, fever, hepatitis, anaphylaxis, etc.), timing, risk factors, detailed medication history including all drugs and timing, dechallenge (response when drug is removed) and rechallenge (response when drug is given again)
- check with literature, Health Canada and FDA; contact the pharmaceutical company
- differentiate between drug therapy vs. disease pathophysiology
- treatment: stop the drug, supportive care, symptomatic relief
- Canadian Adverse Drug Reaction Monitoring Program online
- report all suspected ADRs that are: 1) unexpected, 2) serious, or 3) reactions to recently marketed drugs (on the market <5 years) regardless of nature or severity

Table 4. Sample of Clinically Relevant Adverse Drug Reactions and Interactions

Classification	Drug(s)	Adverse Drug Reaction	Comments
A	Beta-blockers	Bradycardia	Dose dependent
A	ACEI	Cough	Switch ACEI to ARB
B	Vancomycin	Red Man Syndrome	Pruritic erythematous rash on upper body related to rapid infusion of first dose Not considered "allergy"
B	Sulfa Drugs	Stevens-Johnson Syndrome Toxic Epidermal Necrolysis	Life threatening; do not rechallenge under any circumstance
B	Penicillin	Rash	Many children with EBV infection will develop a rash when given amoxicillin; this is NOT a true penicillin allergy
B	Aminoglycosides	Ototoxicity and nephrotoxicity	Dose dependent
B	Acetaminophen, Valproic acid, Chinese herbs	Hepatotoxicity	Many other drugs are hepatotoxic (e.g. statins, OCPs, isoniazid)

Variability in Drug Response

- recommended patient dosing is based on clinical research and represents mean values for a select population, but each person may be unique in their dosing requirements
 - the majority (but not all) of the patients will experience the desired therapeutic effect of a drug with minimal ADRs on the recommended dose
 - may need to adjust dosing or alter medication altogether
- there may be multiple causes of individual variability in drug response at a given dose, and they should be considered when prescribing and dosing medications

- possible causes of variable drug responses include problems with:
 - intake
 - patient adherence, e.g. hard to follow dosing schedule, non-palatable drug, costly drug
 - pharmacokinetics
 - absorption
 - decreased by vomiting, diarrhea or steatorrhea
 - hepatic first pass effect too high due to enzyme induction, or too low due to liver disease
 - absorption change due to drug interactions (e.g. calcium carbonate chelates iron)
 - distribution
 - very high or low percentage body fat, intact or disrupted BBB metabolism
 - patient is elderly or a neonate, or has liver dysfunction
 - certain genetic polymorphisms or lack of enzymes to metabolize drugs (e.g. acetylcholinesterase deficiency, CYP polymorphism)
 - metabolism increased by enzymatic induction or decreased by enzymatic inhibition
 - elimination
 - kidney or liver dysfunction, or obstruction of bile elimination pathway
 - pharmacodynamics
 - genetic variability in drug response (e.g. malignant hyperthermia due to specific anesthetic agents)
 - drug interactions (e.g. polypharmacy) or disease process that affects drug pharmacodynamics
 - drug tolerance

Autonomic Pharmacology

Figure 12. Autonomic Nervous System (ANS) Efferent Tracts

Figure 11. Subdivisions of the Peripheral Nervous System

- most organs are innervated by both sympathetic and parasympathetic nerves; these have opposing effects (see Figure 13)
- almost all ANS efferent tracts are divided into preganglionic and postganglionic nerves, which synapse in the autonomic ganglion (see Figure 12)
- sympathetic preganglionic fibers originate in the spinal cord at spinal levels T1-L3, and terminate in one of two ganglia
 - paravertebral ganglia, i.e. the sympathetic trunk, that lie in a chain close to the vertebral column
 - pre-vertebral ganglia, i.e. celiac and mesenteric ganglia, that lie within the abdomen
- parasympathetic preganglionic fibers originate in the lower brainstem from cranial nerves III, VII, IX, X, and in the sacral spinal cord at levels S2-S4; they terminate in the ganglionic cells located near or within the target organ
- both sympathetic and parasympathetic pre-ganglionic nerves release ACh which acts on a nicotinic receptor
- post-ganglionic sympathetic nerves release NE, which acts on alpha and beta receptors, while post-ganglionic parasympathetic nerves release ACh which acts on muscarinic receptors
- the exceptions are post-ganglionic sympathetic nerves to blood vessels, sweat glands, spleen capsule, adrenals, which do NOT have parasympathetic innervation

Figure 13. Autonomic Nervous System

Parasympathetic Nervous System (PNS)

- acetylcholine (ACh) is the main neurotransmitter of the parasympathetic nervous system
- ACh receptors include
 - nicotinic (pre-ganglionic) receptors located in the autonomic ganglia, and nicotinic (post-ganglionic) receptors in the adrenal medulla
 - muscarinic (only post-ganglionic) receptors
 - M_1 located in the CNS
 - M_2 receptors located on smooth muscle, cardiac muscle and glandular epithelium
- acetylcholine action is terminated by metabolism in the synaptic cleft by acetylcholinesterase and in the plasma by pseudocholinesterase
 - e.g. acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine) are used to increase ACh levels in conditions such as myasthenia gravis and Alzheimer's disease

Sympathetic Nervous System (SNS)

- norepinephrine is the major neurotransmitter of the SNS
- receptors include
 - β_1 : predominately in cardiac tissue
 - β_2 : predominately in smooth muscle and glands
 - α_1 : predominately on post-synaptic receptors in smooth muscles and glands
 - α_2 : predominately on pre-synaptic terminals, where they feed back to inhibit further NE release; also exist as post-synaptic terminals in the brain, uterus and vascular smooth muscle
- norepinephrine action is terminated by reuptake by the presynaptic membrane, diffusion from the synaptic cleft and degradation by monoamine oxidase (MAO) and catechol-O-methyl transferase (COMT)

Table 5. Direct Effects of Autonomic Innervation on the Cardiorespiratory System

Organ	Sympathetic Nervous System		Parasympathetic Nervous System	
	Receptor	Action	Receptor	Action
Heart				
1. Sinoatrial	β_1	Increased HR	M	Decreased HR
2. Atrioventricular Node	β_1	Increased conduction	M	Decreased conduction
3. Atria	β_1	Increased contractility	M	Decreased conduction
4. Ventricles	β_1	Increased contractility	M	Decreased conduction
Blood Vessels				
1. Skin, Splanchnic	α_1, α_2	Constriction	M	Dilatation
2. Skeletal Muscle	α	Constriction	M	Dilatation
	β_2 – large muscles	Dilatation	M	Dilatation
3. Coronary	α_1, α_2	Constriction	M	Dilatation
	β_2	Dilatation	M	Dilatation
Lungs				
1. Bronchiolar Smooth Muscle	β_2	Relaxation	M	Constriction
2. Bronchiolar Glands	α_1, β_2	Increased secretion	M	Stimulation

Opioid Analgesics

- in general, when converting from PO to IV, divide by a factor of 2
- when converting from one opioid to another, use 50-75% of the equivalent dose to allow for incomplete cross-tolerance
- rapid titration and prn use may be required to ensure effective analgesia for the first 24 hours
- dose equivalencies provided in the above table are approximate; individual patients vary
- opioids often used to manage mild to moderate pain include codeine, hydrocodone, and oxycodone
- moderate to severe pain is often managed using morphine, hydromorphone, oxycodone, fentanyl, methadone, or levorphanol

Table 6. Opioid Analgesics

Generic Name	Proprietary Name	Comments
Morphine	MS IR® ("immediate release" PO); MS Contin®, M-Eslon® (controlled release PO); various names for IV form	<ul style="list-style-type: none"> • Parenteral 10 mg morphine is usual standard for comparison • Morphine PO:IV = 60:10 for opioid naive patient, 30:10 for others • Do not crush, break, or chew oral controlled release morphine
Codeine	Tylenol® #1, #2, #3 Codeine Contin®, generics	<ul style="list-style-type: none"> • Metabolized to morphine by CYP2D6 (7-10% of Caucasians are non-metabolizers, due to polymorphisms) • Limited by potential toxicities of acetaminophen • No additional benefit at doses > 200 mg
Fentanyl	Sublimaze®	<ul style="list-style-type: none"> • Minimal experience outside the hospital setting
Fentanyl	Duragesic®	<ul style="list-style-type: none"> • Usually for stable pain, especially in patients with GI dysfunction • Transdermal 50 µg/h patch equivalent to 100 mg morphine PO/day
Hydromorphone	Vicodin®, Lortab®	<ul style="list-style-type: none"> • Limited by potential toxicities of acetaminophen or ibuprofen additive • Quick onset of action and thus highly addictive
Hydromorphone	Dilaudid®	<ul style="list-style-type: none"> • PO especially useful for initial dose titration and prn supplementation • IV form often used subcutaneously
Levorphanol	Levodromoran®	<ul style="list-style-type: none"> • Long half-life with relatively short dosing interval
Meperidine	Demerol®	<ul style="list-style-type: none"> • Not a 1st line opioid. May cause seizures due to the accumulation of normeperidine, its breakdown product • Avoid using > 48h, > 600 mg/24h and with MAOIs
Methadone	Dolophine®	<ul style="list-style-type: none"> • Long, variable half-life, which may complicate titration • Better used for withdrawal/abstinence therapy
Oxycodone	OxyContin® Oxy IR®, Endocodone® Percocet®, Percodan® (combination with ASA or acetaminophen)	<ul style="list-style-type: none"> • Often formulated in combination with acetaminophen/aspirin, use caution

When prescribing narcotics, remember **NBAL**:
 Narcotic (e.g. morphine 5 mg PO q4h)
 Breakthrough (e.g. morphine 2.5 mg PO q1h prn)
 Anti-emetic (e.g. metoclopramide 10 mg 30 min before each meal and qhs)
 Laxative (e.g. senokot PO qhs)

Equianalgesic Doses of Opioids		
Drug	PO Dose (mg)	IV Dose (mg)
Codeine	100	50
Morphine	10	3-5
Oxycodone	5	n/a
Hydromorphone	2	1
Hydrocodone	10	n/a

Titrating Opioid Analgesics with Continuous Opioid Infusion

- pain is most effectively managed using a combination of the basal/continuous rate plus PRN bolus/rescue/breakthrough doses
- at the initiation of the infusion, a loading dose of 2-5 times the hourly rate may be required for significant pain
- minimum 8 hours required for a new rate to reach steady state
 - basal/continuous rate should be increased no sooner than 8 hours after the last basal increase (ideally 24 hours between increases)
- use PRN doses – nurse administered or patient controlled analgesia (PCA) – to provide:
 - rapid response to the patient's need for pain relief between scheduled doses
 - a basis for future increases of the basal rate
- rescue/breakthrough doses are equal to 10% of the 24-hour rate, available q1h
- 24 hours after the last basal rate adjustment, calculate the total opioid dose in those 24 hours (basal rate + PRN doses); divide the total by 24 to reach the new hourly rate
- when the basal rate is increased, the rescue/breakthrough dose is changed proportionately to maintain that dose at 10% of the 24-hour dose

Common Drug Endings

Table 7. Common Drug Endings

Ending	Category	Example
-afil	Erectile dysfunction	sildenafil
-ane	Inhaled general anesthetic	halothane
-azepam	Benzodiazepine	lorazepam
-azole	Antifungal	ketoconazole
-olol	β -blocker	propanolol
-pril	ACE inhibitor	captopril
-terol	β_2 agonist	albuterol
-tidine	H ₂ agonist	cimetidine
-tropin	Pituitary hormone	somatotropin
-zosin	α_1 antagonist	prazosin

Note: Some medications are exceptions to the rule e.g. methimazole (antithyroid)

Introduction to Skin

Skin Anatomy

Layers of the Epidermis
"Californians Like Getting Sun Burns"

Figure 1. Cross-Section of the Various Layers of Skin. Epidermal layer is detailed in A

Skin

- divided anatomically into epidermis, dermis, and subcutaneous tissue
- epidermis**
 - avascular: receives its nutrition from the dermal capillaries
 - derived from keratinocytes with the youngest presenting at the 'base' (see layers Figure 1A)
 - cells progress from stratum basale to stratum corneum in about four weeks
 - stratum basale (germinativum): mitotic figures that give rise to keratinocytes
 - stratum spinosum (prickle cells): junctions in this layer (tonofilaments) give the epidermis its strength
 - stratum granulosum: flat cells containing basophilic granules which characterize skin
 - stratum lucidum: comprised of transparent layers of packed dead cells
 - stratum corneum: flat scales of the resistant protein keratin
 - other epidermal cells include melanocytes, Langerhans cells, and white blood cells
- dermis** – comprised of connective tissue divided into two regions:
 - papillary: contains numerous capillaries that supply nutrients to the dermis and epidermis
 - reticular: provides a strong structure for skin; consists of collagen bundles woven together along with elastic fibres, fibroblasts, and macrophages
- subcutaneous tissue** (subdermal)
 - consists primarily of adipose cells

Skin Appendages

- epidermal in origin; can extend into the dermis
- include hair, nails, and cutaneous glands

Cutaneous Glands

- sebaceous gland** – part of pilosebaceous unit, produces sebum which is secreted into the hair follicle via the sebaceous duct, where it covers the skin surface (protective function)
 - sebum has some antifungal properties
 - found over entire skin surface except palms and soles
- apocrine sweat gland** – apocrine duct empties into hair follicle above sebaceous gland
 - found in axillae and perineum
 - main function is to produce scent (i.e. pheromones)
- eccrine sweat gland** – not part of pilosebaceous unit
 - found over entire skin surface except lips, nail beds and glans penis
 - important in temperature regulation via secretion of sweat to cool skin surface

Skin Function

- protection
 - due to continuous recycling and avascularity of epidermis
 - barrier to: UV radiation, mechanical/chemical insults, pathogens and dehydration
- thermal regulation
 - insulation to maintain body temperature in cool environments, via hair and subcutaneous adipose tissue
 - dissipation of heat in warm environments, via increased activity of sweat glands and increased blood flow within dermal vascular networks
- sensation
 - largest sensory organ of the body, with touch, pain, and temperature sensation
- metabolic function
 - vitamin D synthesis
 - energy storage (mainly in the form of triglycerides)

Definitions

Primary Morphological Lesions

Definition

- an initial lesion that has not been altered by trauma or manipulation and has not regressed
- **macule**: flat lesion <1 cm
- **patch**: flat lesion ≥1 cm
- **papule**: elevated, palpable lesion <1 cm
- **plaque**: elevated, palpable lesion ≥1 cm
- **nodule**: deep, palpable lesion <1 cm, often dermal or subcutaneous in origin
- **tumour**: deep, palpable lesion ≥1 cm
- **vesicle**: fluid-filled lesion <1 cm
- **bulla**: fluid-filled lesion ≥1 cm
- **cyst**: a nodule containing semi-solid or fluid material
- **pustule**: an elevated lesion containing purulent fluid (white, grey, yellow, green)
- **erosion**: a disruption of the skin involving the epidermis alone, heals without scarring
- **ulcer**: a disruption of the skin that extends into the dermis or deeper; heals with scarring

Table 1. Types of Lesions

Profile	<1 cm Diameter	≥1 cm Diameter
Flat Lesion	Macule (e.g. freckle)	Patch (e.g. vitiligo)
Raised Superficial Lesion	Papule (e.g. wart)	Plaque (e.g. psoriasis)
Deep Palpable (dermal or subcutaneous)	Nodule (e.g. dermatofibroma)	Tumour (e.g. lipoma)
Elevated Fluid-filled Lesions	Vesicle (e.g. herpes simplex virus (HSV))	Bulla (e.g. bullous pemphigoid)

Secondary Morphological Lesions

Definition

- develop during the evolutionary process of skin disease, or created by manipulation, or due to complication of primary lesion (e.g. rubbing, scratching, infection)
- **crust**: dried fluid (serum, blood, or purulent exudate) originating from a lesion (e.g. impetigo)
- **scale**: excess keratin (e.g. seborrheic dermatitis)
- **lichenification**: thickening of the skin and accentuation of normal skin markings (e.g. chronic atopic dermatitis)
- **fissure**: a linear slit-like cleavage of the skin
- **excoriation**: a scratch mark
- **xerosis**: pathologic dryness of skin (xeroderma), conjunctiva (xerophthalmia), or mucous membranes
- **atrophy**: histological decrease in size and number of cells or tissues, resulting in thinning or depression of the skin

Other Morphological Lesions

- **comedones**: collection of sebum and keratin
 - open comedo (blackhead)
 - closed comedo (whitehead)
- **purpura**: extravasation of blood into dermis resulting in hemorrhagic lesions; non-blanchable
 - **petechiae**: small pinpoint purpura
 - **ecchymoses**: large flat purpura, "bruise"
- **telangiectasia**: dilated superficial blood vessels; blanchable
- **scar**: replacement fibrosis of dermis and subcutaneous tissue (hypertrophic or atrophic)
- **wheal**: a special form of papule or plaque that is blanchable and transient, formed by edema in the dermis (e.g. urticaria)

Describe a Lesion with SCALDA
Size and Surface area
Colour (e.g. hyperpigmented, hypopigmented, erythematous)
Arrangement (e.g. solitary, linear, reticulated, grouped, herpetiform)
Lesion morphology (see Table 1)
Distribution (e.g. dermatomal, intertriginous, symmetrical/asymmetrical, follicular)
Always check hair, nails, mucous membranes and intertriginous areas

Skin Phototypes (Fitzpatrick)

Phototype	Colour of Skin	Skin's Response to Sun Exposure (without SPF protection)
I	White	Always burns, never tans
II	White	Always burns, little tan
III	White	Slight burn, slow tan
IV	Pale brown	Slight burn, faster tan
V	Brown	Rarely burns, dark tan
VI	Dark brown or black	Never burns, dark tan

Patterns and Distribution

- **acral:** relating to the hands and feet (e.g. hand, foot and mouth disease)
- **annular lesions:** ring shaped (e.g. granuloma annulare)
- **follicular lesions:** involving hair follicles (e.g. folliculitis)
- **guttate lesions:** lesions following a “drop-like” pattern (e.g. guttate psoriasis)
- **Koebner phenomenon:** isomorphic response, appearance of lesions at an injury site (e.g. molluscum, lichen planus, psoriasis, warts)
- **morbilliform:** a maculopapular rash resembling measles
- **reticular lesions:** lesions following a net-like pattern (e.g. livedo reticularis)
- **satellite lesions:** lesions scattered outside of primary lesion (e.g. candida diaper dermatitis)
- **serpiginous lesions:** lesions following a snake-like pattern (e.g. cutaneous larva migrans)
- **target (iris) lesions:** concentric ring lesions, like a dartboard (e.g. erythema multiforme)
- **other descriptive terms:** discrete, clustered, linear, confluent, dermatitic, indurated

Differential Diagnoses of Common Presentations

Figure 2. Common Lesions Based on Anatomical Distribution

Table 2. Differential Diagnosis of Common Presenting Problems

Lesion	Infectious	Inflammatory	Drug/Toxin	Miscellaneous
Brown Macule		Post-inflammatory hyper-pigmentation	UV radiation, actinic/solar lentigo, freckle (ephelide)	Congenital: café-au-lait spots, congenital nevus, epidermal/junctional nevus Neoplasia: lentigo maligna, malignant melanoma, pigmented basal cell carcinoma (BCC) Other: melasma/chloasma ("mask of pregnancy")
Discrete Red Papule	Folliculitis Furuncle Scabies	Acne vulgaris Lichen planus Rosacea Psoriasis Urticaria	Bites/stings	Vascular: hemangioma, pyogenic granuloma Other: dermatofibroma, miliaria rubra
Red Scales	Pityriasis rosea Secondary syphilis Tinea	Dermatitis (atopic, contact, nummular, seborrheic) Discoid lupus Lichen planus Psoriasis	Gold	Neoplastic: mycosis fungoides
Vesicle	Cat-Scratch disease Impetigo Viral: HSV, zoster, varicella, molluscum, coxsackie Scabies	Acute contact dermatitis Dyshidrotic eczema		Other: dermatitis herpetiformis, porphyria cutanea tarda
Bullae	Bullous impetigo	Acute dermatitis Erythema Multiforme (EM) Steven-Johnson Syndrome (SJS) Toxic Epidermal Necrosis (TEN) Systemic lupus erythematosus (SLE)	Fixed drug eruption	Autoimmune: bullous pemphigoid, pemphigus vulgaris Other: dermatitis herpetiformis, porphyria cutanea tarda
Pustule	Candida Dermatophyte Impetigo Sepsis Varicella	Acne vulgaris Rosacea Dyshidrotic dermatitis Pustular folliculitis Pustular psoriasis	Acute generalized exanthematous pustulosis (usually secondary to drug reaction)	Other: hidradenitis suppurativa
Oral Ulcer	Aspergillosis CMV Coxsackie Cryptococcosis HSV/HZV HIV, TB, Syphilis	Allergic stomatitis EM/SJS/TEN Lichen planus Seronegatives, SLE Recurrent aphthous stomatitis Behçet's disease	Chemotherapy Radiation therapy	Autoimmune: pemphigus vulgaris Congenital: XXY Hematologic: sickle cell disease Neoplasia: BCC, squamous cell carcinoma (SCC)
Skin Ulcer	Plague Syphilis TB Tularemia	RA, SLE, vasculitis Ulcerative colitis (pyoderma gangrenosum)		Autoimmune: necrobiosis lipoidica diabetorum (e.g. DM) Congenital: XXY Hematologic: sickle cell disease Neoplasia: SCC Vascular: arterial, neurotropic, pressure, venous, aphthous, leukoplakia, traumatic

Common Skin Lesions

Cysts

Table 3. Cysts

	Epidermal Cyst (Sebaceous)	Pilar Cyst (Trichilemmal)	Dermoid Cyst	Ganglion Cyst	Milium
Clinical Presentation	Round, yellow/flesh coloured, slow growing, mobile, firm, fluctuant, nodule or tumour	Multiple, hard, varying sized nodules under the scalp, lacks central punctum	Most commonly found at lateral third of eyebrow or midline under nose	Usually solitary, rubbery, translucent; a clear gelatinous viscous fluid may be extruded	1-2 mm superficial, white to yellow subepidermal papules occurring on eyelids, cheeks, and forehead Within pilosebaceous follicles
Pathophysiology	Epithelial cells displaced into dermis, epidermal lining becomes filled with keratin and lipid-rich debris May be post-traumatic	Thick walled cyst lined with stratified squamous epithelium and filled with dense keratin Idiopathic Post-trauma	Rare, congenital hamartomas, which arise from inclusion of epidermis along embryonal cleft closure lines, creating a thick walled cyst filled with dense keratin	Cystic lesion that originates from joint or tendon sheath, called a mucous cyst when found on fingertip Associated with osteoarthritis	Small epidermoid cyst, primarily arising from pluripotent cells in epidermal or adnexal epithelium Secondary to blistering, ulceration, trauma, topical corticosteroid atrophy, or cosmetic procedures
Epidemiology	Most common cutaneous cyst in youth – mid age	2 nd most common cutaneous cyst F>M	Rare	Older age	Any age 40-50% of infants
Clinical Course	Central punctum may rupture (foul, cheesy odour, creamy colour) and produce inflammatory reaction Increase in size and number over time, especially in pregnancy	Rupture causes pain and inflammation	If nasal midline, risk of extension into CNS	Stable	In newborns, spontaneously resolves in first 4 weeks of life
Management	Excise completely before it becomes infected	Excision	Excision	Drainage ± steroid injection if painful Compression daily for 6 weeks Excision if bothersome	Incision and expression of contents Laser ablation and electrodesiccation Multiple facial milia responds to topical retinoid therapy

Fibrous Lesions

DERMATOFIBROMA

Clinical Presentation

- button-like, firm dermal papule or nodule, skin-coloured to red-brown colouring
- majority are asymptomatic but may be pruritic and/or tender
- site: legs > arms > trunk
- dimple sign: lateral compression causes dimpling of the lesion

Pathophysiology

- benign tumour due to fibroblast proliferation in the dermis

Etiology

- unknown; often associated with history of minor trauma (e.g. shaving or insect bites)

Epidemiology

- adults, F>M

Differential Diagnosis

- dermatofibrosarcoma protuberans, malignant melanoma, Kaposi's sarcoma, blue nevus

Investigations

- biopsy if diagnosis is uncertain

Management

- no treatment required
- excision or cryosurgery if bothersome

SKIN TAGS**Clinical Presentation**

- small (1-10 mm), soft, skin-coloured or darker pedunculated papule, often polypoid
- sites: eyelids, neck, axillae, inframammary, and groin

Pathophysiology

- benign outgrowth of skin

Epidemiology

- middle-aged and elderly, F>M, obese

Differential Diagnosis

- pedunculated seborrheic keratosis, compound or dermal melanocytic nevus, neurofibroma

Management

- excision, electrodesiccation, cryosurgery

**Skin tags are also known as...**

- Acrochordons
- Fibroepithelial polyps
- Soft fibromas
- Pedunculated lipofibromas
- Cutaneous papillomas

Hyperkeratotic Lesions

SEBORRHEIC KERATOSIS**Clinical Presentation**

- well-demarcated waxy papule/plaque with classic “stuck on” appearance
- large variety in colour, size and shape
- over time lesions appear more warty, greasy and pigmented
- sites: face, trunk, upper extremities (may occur at any site except palms or soles)

Pathophysiology

- very common benign epithelial tumour

Epidemiology

- unusual <30 years old
- autosomal dominant inheritance

Differential Diagnosis

- malignant melanoma (lentigo maligna, nodular melanoma), melanocytic nevi, pigmented basal cell carcinoma, solar lentigo, spreading pigmented actinic keratosis

Investigations

- biopsy only if diagnosis uncertain

Management

- none required, for cosmetics only
- liquid nitrogen, curettage

ACTINIC KERATOSIS (SOLAR KERATOSIS)**Clinical Presentation**

- ill-defined, scaly erythematous papules or plaques on a background of sun damaged skin (solar heliosis)
- sandpaper-like, gritty sensation felt on palpation
- sites: areas of sun exposure (face, ears, scalp if bald, neck, sun exposed limbs)

Pathophysiology

- UV radiation damage to keratinocytes from repeated sun exposure (especially UVB)
- can develop into squamous cell carcinoma (1-10%)

**Types of Actinic Keratoses (AKs)**

- **Erythematous** – typical AK lesion
- **Hypertrophic** – thicker, rough papule/plaque
- **Cutaneous horn** – firm hyperkeratotic outgrowth
- **Actinic cheilitis** – confluent AKs on the lip
- **Pigmented** – flat, tan-brown, scaly plaque
- **Spreading pigmented**
- **Proliferative**
- **Conjunctival** – pinguecula, pterygium

Epidemiology

- common with increasing age, outdoor occupation, M>F
- skin phototypes I-III (see sidebar, D3), rare in darker skin as melanin is protective

Differential Diagnosis

- SCC in situ, superficial BCC, seborrheic keratosis, cutaneous lupus erythematosus

Investigations

- biopsy lesions that are refractory to treatment

Management

- destructive: liquid nitrogen, electrodesiccation and curettage
- pharmacotherapy: Efudex® (5-fluorouracil) cream for 2-3 weeks, Aldara® (imiquimod) cream for 8-10 weeks

**KERATOACANTHOMA****Clinical Presentation**

- rapid growing, firm, dome-shaped, erythematous or skin-coloured nodule with central keratin-filled crater, resembling an erupting volcano
- often spontaneously regresses within a year, leaving a scar
- sites: sun-exposed skin

Pathophysiology

- epithelial neoplasm with atypical keratinocytes in epidermis
- considered a low grade variant of SCC

Etiology

- HPV, UV radiation, chemical carcinogens (tar, mineral oil)

Epidemiology

- >50 years, rare <20 years

Differential Diagnosis

- treat as SCC until proven otherwise, hypertrophic solar keratosis, verruca vulgaris

Management

- surgical excision

CORNS**Clinical Presentation**

- firm papule with a central, translucent, cone-shaped, hard keratin core
- painful with direct pressure
- sites: most commonly on dorsolateral fifth toe and dorsal aspects of other toes

Pathophysiology

- localized hyperkeratosis induced by pressure on hands and feet

Epidemiology

- F>M, can be caused by wearing high-heeled shoes with a tapered toe

Differential Diagnosis

- tinea pedis, plantar warts

Management

- relieve pressure with padding or alternate footwear
- paring, curettage

**Corns vs. Warts vs. Callouses**

- Corns have a whitish yellow central translucent keratinous core. Painful with direct pressure.
- Warts bleed with paring and have a black speckled central appearance due to thrombosed capillaries. Plantar warts destroy dermatoglyphics (epidermal ridges).
- Callouses have layers of yellowish keratin revealed with paring. There are no thrombosed capillaries or interruption of epidermal ridges.

Keloids

Clinical Presentation

- firm, shiny, skin-coloured or red-bluish papules/nodules that most often arise from cutaneous injury (e.g. piercing, surgical scar, acne), but may appear spontaneously
- extends beyond the margins of the original injury, and may continue to expand in size for years with claw-like extensions
- can be pruritic and painful
- sites: earlobes, shoulders, sternum, scapular area

Pathophysiology

- excessive proliferation of randomly organized collagen fibers following trauma to skin
- differentiated from a hypertrophic scar which is confined to the borders of the original injury

Epidemiology

- predilection for darker skin
- M=F; all age groups

Management

- intralesional corticosteroid injections
- cryotherapy
- silicone compression

Keloids vs. Hypertrophic Scars

- **Keloids:** extend beyond margins of original injury with claw-like extensions
- **Hypertrophic scars:** confined to original margins of injury

Pigmented Lesions

Table 4. Comparison of Pigmented Lesions

	Ephelides (Freckles)	Solar Lentigo (Liver Spot)	Mongolian Spot	Becker's Nevus
Clinical Presentation	Small (<5 mm) well-demarcated light brown macules Sites: sun-exposed skin	Well demarcated brown/black irregular macules Sites: sun-exposed skin	Congenital grey-blue macule commonly on lumbosacral area	Hairy, light brown macule/patch with a papular verrucous surface Sites: trunk and shoulders
Pathophysiology	Increased melanin within basal layer keratinocytes secondary to sun exposure	Benign melanocytic proliferation in dermal-epidermal junction due to chronic sun exposure	Ectopic melanocytes in dermis	Pigmented hamartoma with increased melanin in basal cells
Epidemiology	Skin phototypes I and II	Most common in Caucasians > 40 years Skin phototype I-III	99% occurs in Asian and Aboriginal infants	M>F Often becomes noticeable at puberty
Differential Diagnosis	Junctional nevi Juvenile lentigines	Lentigo maligna, seborrheic keratosis, pigmented solar keratosis	Ecchymosis	Hairy congenital melanocytic nevus
Clinical Course and Management	No treatment required Multiply and darken with sun exposure, fade in winter Sunscreens may prevent the appearance of new freckles	Laser therapy, shave excisions, cryotherapy	Usually fades in early childhood but may persist into adulthood	Hair growth follows onset of pigmentation Cosmetic management (usually too large to remove)

DDx of Hyperpigmented Macules

- Purpura (e.g. solar, ASA, anti-coagulants, steroids, hemosiderin stain)
- Post-inflammatory
- Melasma
- Melanoma
- Fixed drug eruption

SEBORRHEIC KERATOSIS (see *Hyperkeratotic Lesions* section, D7)

NEVOMELANOCYTIC NEVI (NMN) (see Table 5)

- common mole
- be suspicious of new pigmented lesions in individuals >40 years
- average number of moles per person: 18-40
- 3 stages of evolution:
 - junctional NMN: macular; arise at dermal-epidermal junction
 - compound NMN: papular; nevus cells invade the papillary dermis
 - dermal NMN: skin coloured papules (no longer hyperpigmented); nevus cells completely migrate into dermis

Table 5. Nevomelanocytic Nevi Classification

Type	Age of Onset	Clinical Presentation	Histology	Management
Congenital NMN	Birth	Sharply demarcated pigmented brown plaque with regular/irregular contours \pm coarse hairs Rule out leptomeningeal involvement if on head/neck	Nevomelanocytes in epidermis (clusters) and dermis (strands)	Surgical excision if suspicious, due to increased risk of melanoma
Acquired NMN	Early childhood to age 40 Involute by age 60	Benign neoplasm of pigment-forming nevus cell Well circumscribed, round, uniformly pigmented macules/papules <1.5 cm Classified according to site of nevus cells		Excisional biopsy required if on scalp, soles, mucous membranes, anogenital area, or if varied colours, irregular borders, pruritic, bleeding, exposed to trauma
Junctional NMN	Childhood Majority progress to compound nevus	Flat, irregularly bordered, uniformly tan-dark brown, sharply demarcated smooth macule	Melanocytes at dermal-epidermal junction above basement membrane	Same as above
Compound NMN	Any age	Domed, regularly bordered, smooth, round, tan-dark brown papule Face, trunk, extremities, scalp NOT found on palms or soles	Melanocytes at dermal-epidermal junction; migration into dermis	Same as above
Dermal NMN	Adults	Soft, dome-shaped, skin-coloured to tan/brown papules or nodules, often with telangiectasia Sites: face, neck	Melanocytes exclusively in dermis	Same as above
Dysplastic NMN	Childhood	Variegated macule/papule with irregular indistinct melanocytes in the basal cell layer >6 mm Risk factors: positive family history	Hyperplasia and proliferation of melanocytes extending beyond dermal compartment of the nevus Often with region of adjacent nests	Follow q2-6 months with colour photographs for changes Excisional biopsy if lesion changing or highly atypical
Halo NMN	First 3 decades	Brown oval/round papules surrounded by hypomelanosis Same sites as nevocellular nevus Spontaneous involution with regression of centrally located pigmented nevus	Dermal or compound nevocellular nevus surrounded by hypomelanosis, lymphocytes, histocytes	None required Excision if colour variegated or irregular borders Associated with vitiligo, metastatic melanoma
Blue NMN	Childhood and late adolescence	Uniformly blue to blue-black macule/papule with smooth border <6 mm	Pigmented melanocytes and melanophages in dermis	Remove if sudden onset or has changed

Vascular Lesions

Table 6. Vascular Tumours Compared to Vascular Malformations

	Vascular Tumours	Vascular Malformations
Definition	Endothelial hyperplasia	Normal endothelial turnover
Presence at Birth	Usually postnatal	100% at birth (not always obvious)
M:F	1:3-1:5	1:1
Natural History	Phases: • Proliferating • Involuting • Involved	Proportionate growth (can expand)

HEMANGIOMAS

Clinical Presentation

- is a vascular tumour, defines as benign proliferation of vessels in the dermis
- is red or blue, nodular and blanches with pressure
- includes: cavernous hemangioma, capillary/infantile hemangioma, spider hemangioma

Table 7. Vascular Tumours

	Hemangioma	Capillary/Infantile (spider strawberry nevus)	Spider Angioma (Campbell telangiectasia)	Cherry Angioma (Demorgan spot)	Pyogenic Granuloma
Clinical Presentation	Soft, compressible, bluish, subcutaneous mass that feels like a bag of worms when palpated Site: anywhere (distribution may indicate underlying cranial abnormality)	Congenital red/blue nodules	Central red arteriole with slender branches, faintly pulsatile, blanchable Sites: face, forearms, and hands	Bright red to deep maroon, dome-shaped vascular papules, 1-5 mm Site: trunk Less friable compared to pyogenic granulomas	Bright red, dome-shaped sessile or pedunculated nodule Sites: fingers, lips, mouth, trunk, toes DDx: glomus tumour, nodular malignant melanoma, SCC, nodular BCC
Pathophysiology	Deeply situated proliferation of thick-walled blood vessels	Congenital benign vascular proliferation of endothelial lining (consumptive thrombocytopenia if hemangioma enlarges rapidly) Can be part of PHACES syndrome	Associated with hyperestrogenic state (e.g. in hepatocellular disease, pregnancy, oral contraceptive pill)	Benign vascular neoplasm	Rapidly developing hemangioma Proliferation of capillaries with erosion of epidermis and neutrophilia
Epidemiology	Can be congenital Most appear later			>30 years old	<30 years old
Clinical Course	Can ulcerate Persists, generally do not involute	Appears shortly after 9 months, increases in size over months, then regresses 50% of lesions resolve spontaneously by 5 years	Increase in number over time	Lesions bleed frequently and persist for months	
Management	Surgical removal	Consider excision if not gone by school age. 10% require treatment due to functional impairment (visual compromise, airway obstruction, high output cardiac failure) or cosmesis Propranolol; systemic corticosteroids	Electro or laser surgery Systemic corticosteroids and INF- α may be indicated for rapidly growing lesions	Usually no treatment needed Laser or electrocautery for small lesions Excision of large lesions if necessary	Surgical excision with histologic examination Electrocautery; laser; cryotherapy

A spider angioma will blanch when the tip of a paperclip is applied to the centre of the lesion.

Pyogenic Granuloma is a misnomer: it is neither pyogenic nor granulomatous.

VASCULAR MALFORMATIONS

1. Nevus flammeus (Port-wine stain)

Clinical Presentation

- red to blue macule present at birth that follows a dermatomal distribution, rarely crosses midline
- most common site: nape of neck

Pathophysiology

- congenital vascular malformation of dermal capillaries; associated with Sturge Weber syndrome (V1, V2 distribution)

Management

- laser or camouflage (i.e. make-up)

2. Nevus simplex (salmon patch)

Clinical Presentation

- pink-red irregular patches
- midline macule on glabella known as "Angel Kiss"; on nuchal region known as "Stork Bites"
- present in 1/3 of newborns
- majority regress spontaneously

Pathophysiology

- congenital dilation of dermal capillaries

Management

- no treatment required

Figure 3. Types of Acne

**Acne Myths Debunked**

- Eating greasy food and chocolate does not cause or worsen acne
- Blackheads (comedones) are black because of oxidized melanin, not dirt

**Acne Exacerbating Factors**

- Systemic medications: lithium, phenytoin, steroids, halogens, androgens, iodides, bromides, danazol
- Topical agents: steroids, tars, ointments, oily cosmetics
- Mechanical pressure or occlusion, such as leaning face on hands
- Emotional stress

Acneiform Eruptions

Acne Vulgaris/Common Acne

Clinical Presentation

- a common inflammatory pilosebaceous disease categorized with respect to severity
 - Type I – **comedonal**, sparse, no scarring
 - Type II – comedonal, **papular**, moderate \pm little scarring
 - Type III – comedonal, papular, and **pustular**, with scarring
 - Type IV – **nodulocystic** acne, risk of severe scarring
- predilection sites: face, neck, upper chest, and back

Pathogenesis

- follicular hyperkeratinization blocks the secretion of sebum (comedones)
- androgens stimulate sebaceous glands to produce sebum
- anaerobic diphtheroid *Propionibacterium acnes* bacteria contains lipase, which converts sebum to free fatty acids and produces pro-inflammatory mediators

Epidemiology

- age of onset in puberty (10-17 years in females, 14-19 years in males)
- more severe in males than in females
- incidence decreases in adulthood
- genetic predisposition: majority of individuals with cystic acne have parent(s) with history of severe acne

Differential Diagnosis

- folliculitis, keratosis pilaris (upper arms, face, thighs), perioral dermatitis, rosacea

Management

- see Table 8

Table 8. Acne Treatments and Mechanisms of Action

Drug Name	Mechanism of Action	Notes
MILD ACNE: Topical Therapies		
clindamycin phosphate (e.g. Dalacin T®)	Lincosamide antibiotic; inhibits protein synthesis	Generally regarded as unsafe in lactation
erythromycin	Macrolide antibiotic; inhibits protein synthesis	Local skin reactions include burning, peeling, dryness, pruritus, erythema
benzoyl peroxide	Protein oxidant with bactericidal effect	Dry skin, contact dermatitis Apply to the point of dryness and erythema, but not discomfort
BenzaClin® gel	1% clindamycin and 5% benzoyl peroxide	See above
erythromycin + benzoyl peroxide (Benzamycin®)	3% erythromycin and 5% benzoyl peroxide	See above
adapalene (e.g. Differin®)	Comedolytic	Less irritating than tretinoin. No interaction with sun
tretinoin (e.g. Retin-A®)	Comedolytic	Sun sensitivity and irritation
MODERATE ACNE: After topical treatments have failed, add oral antibiotics, such as tetracycline (500 mg PO daily to bid), or erythromycin (500 mg PO bid). Antibiotics require 3-6 months of use before assessing efficacy. Consider hormonal therapy, including antiandrogens		
tetracycline	Systemic antibiotic	Use caution with regard to drug interactions: do not use with isotretinoin
cyproterone acetate-ethinyl estradiol (Diane-35®)	Cyproterone: potent anti-androgenic, progestogenic and antigonadotrophic activity Ethinyl estradiol: increases level of sex hormone binding globulin (SHBG), reducing circulating plasma levels of androgens	After 35 years of age, estrogen/progesterone should only be considered in exceptional circumstances, carefully weighing the risk/benefit ratio with physician guidance

Table 8. Acne Treatments and Mechanisms of Action (continued)

Drug Name	Mechanism of Action	Notes
SEVERE ACNE: Consider systemic retinoids after above treatments have failed		
isotretinoin (Accutane®, Clarus®)	Retinoid that inhibits sebaceous gland function and regulates keratinization	Teratogenic: contraindicated during pregnancy, unsafe in lactation; reliable contraception is necessary Signed informed consent is needed when prescribing Baseline lipid profile, hepatic enzymes and β -hCG before treatment May transiently exacerbate acne May cause depression Drug may be discontinued at 16-20 weeks when nodule count has dropped by >70% A second course may be initiated after 2 months prn Refractory cases may require 3 or more courses of isotretinoin

**Isotretinoin and Lipids**

Case reports indicate isotretinoin-induced hypertriglyceridemia can be successfully controlled with concurrent hypolipidemic therapy.

Perioral Dermatitis

Clinical Presentation

- discrete erythematous micropapules that often become confluent, forming inflammatory plaques on perioral and periorbital skin
- commonly symmetrical, rim of sparing around vermilion border of lips
- aggravated by topical glucocorticoids

Epidemiology

- 15-40 years old
- predominantly females

Differential Diagnosis

- dermatitis, rosacea, acne vulgaris

Management

- topical: metronidazole 0.75% gel or 0.75-1% cream to area BID
- systemic: tetracycline

Rosacea

Clinical Presentation

- chronic acneiform, inflammatory skin disease
- flushing (transient erythema) with a burning sensation is common initially, however non-transient erythema is the commonest sign of rosacea
- dome-shaped red papules \pm pustules, contributing to a florid, ruddy complexion
- differentiated from acne by the absence of comedones
- sites typically affected: convexities of the central face (forehead, nose, cheeks and chin)
 - may also affect the scalp, neck, and the upper part of body
- characterized by remissions and exacerbations
- all forms of rosacea can progress from mild to moderate to severe
- in longstanding rosacea, signs of thickening, induration, lymphedema in the skin
- phyma: a distinct swelling caused by lymphedema and hypertrophy of subcutaneous tissue, particularly affecting the nose (rhinophyma)
- ocular manifestations: conjunctivitis, keratitis, iritis
- exacerbating factors: heat, cold, wind, sun, stress, drinking hot liquids, alcohol, caffeine, spices (triggers of vasodilatation)

Pathophysiology

- unknown

Epidemiology

- although found in all skin types, highest prevalence in fair-skinned people
- 30-50 years old
- F>M

**Guidelines for the Diagnosis of Rosacea**

Presence of one or more of the following primary features:

- Flushing (transient erythema)
- Nontransient erythema
- Papules and pustules
- Telangiectasia

May include one or more of the following secondary features:

- Burning or stinging
- Plaque
- Dry appearance
- Edema
- Phymatous changes
- Ocular manifestations
- Peripheral location

Subtypes and Variants of Rosacea and Their Characteristics

SUBTYPE

Erythematotelangiectatic

Flushing, persistent central facial erythema ± telangiectasia

Papulopustular

Persistent central facial erythema
Transient central facial papules or pustules or both

Phymatous

Thickening skin, irregular surface nodularities and enlargement
Nose, chin, forehead, cheeks or ears

Ocular

Foreign body sensation in the eye, burning or stinging, dryness, itching, ocular photosensitivity, blurred vision, telangiectasia of the sclera or other parts of the eye, or periorbital edema

VARIANT

Granulomatous

Noninflammatory, hard, brown, yellow, or red cutaneous papules or nodules of uniform size

Management

- avoid topical corticosteroids
- cosmetic camouflage
- telangiectasia: treated by physical ablation; electrical hyfrecators, vascular lasers, and intense pulsed light therapies
- phymas: treated by physical ablation or removal; paring, electrosurgery, cryotherapy, laser therapy [CO₂, argon, neodymium-doped yttrium aluminum garnet (Nd:YAG)]
- early diagnosis and prompt treatment are recommended to prevent worsening

Table 9. Specific Rosacea Treatments

1st Line	2nd Line	3rd Line
Oral tetracyclines (250-500 mg PO bid)	Topical clindamycin	Oral retinoids
Topical metronidazole	Topical erythromycin 2% solution	Topical sulfur
Oral erythromycin (250-500 mg PO bid)	Topical benzoyl peroxide	
	Oral metronidazole	
	Ampicillin	

Dermatitis (Eczema)

Definition

- inflammation of the skin

Clinical Presentation

- symptoms include pruritus and pain
- acute dermatitis: papules, vesicles
- subacute dermatitis: scaling, crusting
- chronic dermatitis: lichenification, xerosis, fissuring

Asteatotic Dermatitis

Clinical Presentation

- diffuse, mild pruritic dermatitis secondary to dry skin
- very common in elderly, especially in the winter (a.k.a. “winter itch”) but starts in the fall

Management

- skin rehydration with moisturizing routine
- ± mild corticosteroid creams

Atopic Dermatitis

Clinical Presentation

- subacute and chronic eczematous reaction associated with prolonged severe pruritus
- distribution
 - infant (onset at 2-6 months old): face, scalp, extensor surfaces
 - childhood (>18 months): flexural surfaces
 - adult: hands, feet, flexures, wrists, face, forehead, eyelids, neck
- inflammation, lichenification, excoriations are secondary to relentless scratching
- atopic palms: prominent palmar creases
- associated with
 - keratosis pilaris (hyperkeratosis of hair follicles, “chicken skin”)
 - xerosis
 - occupational hand dryness

Epidemiology

- frequently affects infants, children, and young adults
- females only slightly more at risk than males (1.3:1 over the age of 2 years)
- almost 15% of children in developed countries under the age of 5 are affected; half of these cases are diagnosed by 1 year of age
- associated with personal or family history of atopy (asthma, hay fever, anaphylaxis, eosinophilia)
- polygenic inheritance: one parent >60% chance for child; two parents >80% chance for child
- childhood onset and hereditary forms may be associated with a defect in the protein filaggrin
- the earlier the onset, the more severe and persistent the disease
- long-term condition with 1/3 of patients continuing to show signs of AD into adulthood

Pathophysiology

- Th2 cellular response

Investigations

- no gold standard for diagnosis
- consider: skin biopsy, immunoglobulin serum levels (often elevated serum IgE level), patch testing, and skin prick tests

Triggers for Atopic Dermatitis

- Irritants (detergents, solvents, clothing, water hardness)
- Contact allergens
- Environmental aeroallergens (dust mites)
- Inappropriate bathing habits (long hot showers)
- Sweating
- Microbes (*S. aureus*)
- Stress

Management

- goal: reduce signs and symptoms, prevent or reduce recurrences/flares
- better outcome (e.g. less flare-ups, modified course of disease) if diagnosis made early and treatment plan individualized
 - individualized based on age, severity, sites and extent of involvement, presence of infection, previous responses to therapy
- avoid triggers of AD
- **enhance barrier function of the skin**
 - regular application of moisturizers
 - emollients hydrate the skin and reduce pruritus
 - twice daily application is recommended even in absence of symptoms, especially after bathing or swimming
 - bathing promotes hydration when followed by the application of moisturizers to the skin
- **anti-inflammatory therapies**
 - topical corticosteroids
 - effective, rapid symptomatic relief of acute flares
 - best applied immediately after bathing
 - control inflammation with a potent topical steroid; a milder one following resolution of acute flare
 - systemic immunosuppression may be needed in severe cases
 - flares may respond to systemic anti-staphylococcal therapy
 - side effects: skin atrophy, purpura, striae, steroid acne, perioral dermatitis, and glaucoma when used around the eyes
 - topical immunomodulators
 - long-term management
 - calcineurin inhibitors include pimecrolimus (Elidel®), tacrolimus (Protopic®)
 - side effects: skin burning, transient irritation
 - advantages of immunomodulators over long-term corticosteroid use
 - ♦ rapid, sustained effect in controlling pruritus
 - ♦ no skin atrophy
 - ♦ safe for the face and neck

Complications

- infections
 - treatment of infections
 - ♦ topical mupirocin or fusidic acid
 - ♦ oral antibiotics (e.g. cloxacillin, cephalexin) for widespread *S. aureus* infections

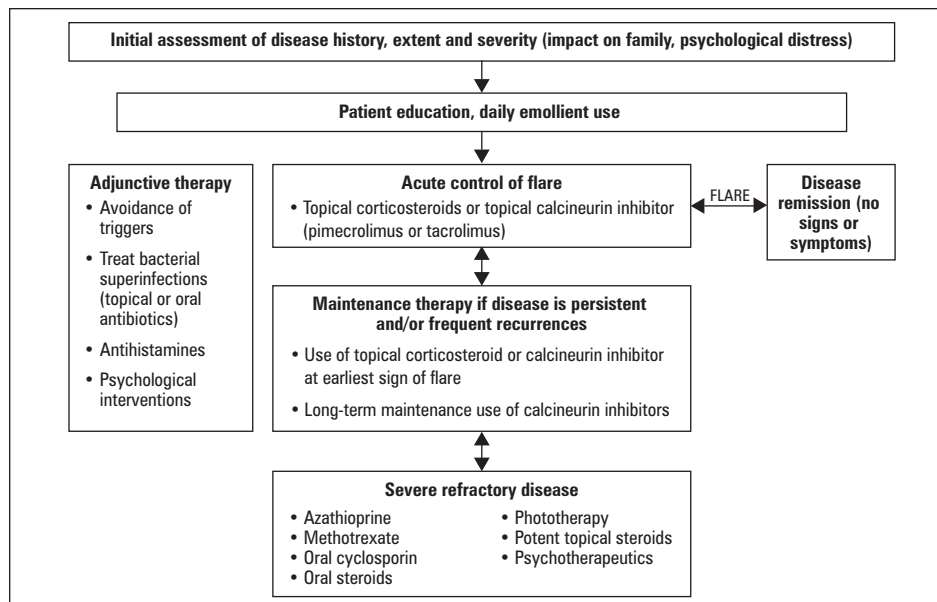

Figure 4. Atopic Dermatitis Treatment Algorithm

Adapted from: Ellis C, et al. ICCAD II Faculty. International Consensus Conference on Atopic Dermatitis II (ICCAD II): clinical update and current treatment strategies. *Br J Dermatol.* 2003; 148 (Suppl 63):3-10.

Contact Dermatitis

Top Ten Allergens as Identified by The North American Contact Dermatitis Group

Test Substance	Allergic Reactions (%)	Common Uses
Nickel sulfate	14.2	Found in some jewelry, buckles
Neomycin sulfate	13.1	Most commonly used topical antibiotic
Balsam of Peru	11.8	Fragrance material
Fragrance mix	11.7	A mix of eight different fragrance components which was developed to allow for allergen testing in cosmetics
Thimerosal	10.9	A common preservative that is used in vaccines, contact lens solution, cosmetics
Sodium gold	9.5	Used in jewellery, dentistry, thiosulfate electronics
Formaldehyde	9.3	A colourless gas found in many workplaces, cosmetics, medications, textiles, resins, plastic bottles
Quaternium-15	9.0	A component in many shampoos, moisturizers, conditioners and soaps
Cobalt chloride	9.0	A hard metal found in cosmetics, jewellery, buttons, tools
Bacitracin	8.7	A topical antibiotic

Clinical Presentation

- cutaneous inflammation from the interaction between external agent(s) and the skin

Table 10. Contact Dermatitis

	Irritant Contact Dermatitis	Allergic Contact Dermatitis
Mechanism of Reaction	Toxic injury to skin; non-immune mechanism	Cell-mediated delayed (Type IV) hypersensitivity reaction
Type of Reaction	Erythema, dryness, fine scale, burning Acute: quick reaction, sharp margins (e.g. from acid/alkali exposure) Cumulative insult: slow to appear, poorly defined margins (e.g. from soap), more common	Erythema with a papulovesicular eruption, swelling, pruritus
Frequency of Contact Dermatitis	Majority; will occur in anyone given sufficient concentration of irritants	Minority; patient acquires susceptibility to allergen that persists indefinitely
Distribution	Palmar surface of hand usually involved	Dorsum of hand usually involved; often discrete area of skin involvement
Examples	Soaps, weak alkali, detergents, organic solvents, alcohol, oils	(See sidebar) Many allergens are irritants, so may coincide with irritant dermatitis
Management	Avoidance of irritants Wet compresses with Burow's solution Barrier moisturizers Topical/oral steroids	Patch testing to determine specific allergen Avoid allergen and its cross-reactants Wet compresses soaked in Burow's solution (drying agent) Steroid cream (hydrocortisone 1%, betamethasone valerate 0.05% or 0.1% cream; bid) Systemic steroids prn (prednisone 1mg/kg, taper over 2 weeks)

Dyshidrotic Dermatitis

Clinical Presentation

- "tapioca pudding" papulovesicular dermatitis of hands and feet that coalesce into plaques, followed by painful fissuring
- acute stage often very pruritic
- secondary infection common
- lesions heal with desquamation and may lead to chronic lichenification
- sites: palms and soles ± dorsal surfaces of hands and feet

Pathophysiology

- NOT caused by hyperhidrosis (excessive sweating)
- emotional stress may precipitate the dermatitis

Management

- topical: high potency corticosteroid with plastic cling wrap occlusion to increase penetration
- intralesional triamcinolone
- systemic:
 - prednisone in severe cases
 - antibiotics for secondary *S. aureus* infection

Nummular Dermatitis

Clinical Presentation

- annular, coin-shaped, pruritic, erythematous plaques, dry, scaly, lichenified
- often associated with atopic and dyshidrotic dermatitis
- secondary infection common

Management

- moisturization
- corticosteroid ointment BID

Seborrheic Dermatitis

Clinical Presentation

- greasy, erythematous, yellow, scaling papules and plaques in areas rich in sebaceous glands
- infants: one cause of “cradle cap”
- children: may be generalized with flexural and scalp involvement
- adults: diffuse involvement of scalp margin with yellow to white flakes, pruritus, and underlying erythema
- sites: scalp, eyebrows, eyelashes, beard, glabella, post-auricular, over sternum, trunk, body folds, genitalia

Pathophysiology

- possible etiologic association with *Pityrosporum ovale* (yeast)

Epidemiology

- common in infants and at puberty
- increased incidence in immunocompromised patients (e.g. HIV)
- in adults, can cause dandruff (pityriasis sicca)

Management

- face: Nizoral® cream OD + mild steroid cream OD or BID
- scalp: salicylic acid in olive oil or Derma-Smoother FS® lotion (peanut oil, mineral oil, fluocinolone acetonide 0.01%) to remove dense scales, 2% ketoconazole shampoo (Nizoral®), ciclopirox (Stieprox®) shampoo, selenium sulfide (e.g. Selsun®) or zinc pyrithione (e.g. Head and Shoulders®) shampoo, steroid lotion (e.g. betamethasone valerate 0.1% lotion bid)

Stasis Dermatitis

Clinical Presentation

- persistent skin inflammation of the lower legs with brown pigmentation, erythema, xerosis, and scaling
- associated with venous insufficiency

Management

- support stockings
- rest and elevate legs
- moisturizer to treat xerosis
- mild topical corticosteroids to control inflammation

Complications

- ulceration (common in medial malleolus), secondary bacterial infections

Lichen Simplex Chronicus

Clinical Presentation

- chronic dermatitis resulting from continued rubbing/scratching of skin
- may develop secondarily to another pruritic skin disease
- lichenified (thickened) skin

Management

- treat pruritus to break the itch-scratch cycle: antihistamines, topical antipruritics
- topical corticosteroids (extremely potent)

Papulosquamous Diseases

Lichen Planus

Clinical Presentation

- acute or chronic inflammation of mucous membranes or skin characterized by violaceous papules, especially on flexural surfaces
- small, polygonal, flat-topped, shiny, violet papules; resolves into hyperpigmented macules
- sites: wrists, ankles, mucous membranes in 60% (mouth, vulva, glans), nails, scalp
- Wickham's striae: greyish lines over surface; pathognomonic
- mucous membrane lesions: lacy, whitish reticular network, milky-white plaques/papules; increased risk of SCC in erosions and ulcers
- nails: longitudinal ridging; dystrophic
- scalp: scarring alopecia
- spontaneously resolves in weeks or lasts for years (mouth and shin lesions)
- Koebner phenomenon "isomorphic reaction": develops in areas of trauma

Epidemiology

- association with hepatitis C
- may be triggered by severe emotional stress

Management

- topical corticosteroids with occlusion or intradermal steroid injections
- short courses of oral prednisone (rarely)
- photochemotherapy for generalized or resistant cases
- oral retinoids for erosive lichen planus in mouth

Pityriasis Rosea

Clinical Presentation

- acute, self-limiting, erythematous eruption characterized by red, oval plaques/patches with central scales that do not extend to edge of lesion
- long axis of lesions follows parallel to ribs producing "Christmas tree" pattern on back
- varied degree of pruritus
- most start with a "Herald" patch which precedes other lesions by 1-2 weeks
- sites: trunk, proximal aspects of arms and legs

Etiology

- suspected human herpes virus 7

Management

- none required; clears spontaneously in 6-12 weeks, reassurance
- topical corticosteroids when post-inflammatory pigmentation is a concern

Psoriasis

Classification

1. plaque psoriasis
2. guttate psoriasis
3. erythrodermic psoriasis
4. pustular psoriasis
5. psoriatic arthritis

Differential Diagnosis

- atopic dermatitis, mycosis fungoides (cutaneous T-cell lymphoma), seborrheic dermatitis, tinea

Diagnosis

- often clinical, biopsy to confirm
- PASI (Psoriasis Area and Severity Index)
 - score is based on: percentage of surface area involved and the severity of symptoms (erythema, infiltration, desquamation)

The 6 P's of Lichen Planus

Purple, Pruritic, Polygonal, Peripheral, Papules, Penis (i.e. mucosa)

PSORIASIS: Presentation and Pathophysiology

Pink papules/Plaques/Pinpoint bleeding (Auspitz sign)/Physical injury (Koebner phenomenon)

Silver scale/Sharp margins

Onycholysis/Oil spots

Rete Ridges with Regular elongation

Itching

Arthritis/Abscess (Munro)/Autoimmune

Stratum corneum with nuclei

Immunologic

Stratum granulosum absent

1. PLAQUE PSORIASIS

Clinical Presentation

- chronic and recurrent disease characterized by well-circumscribed erythematous papules/plaques with silvery-white scales
- worse in winter (lack of sun and humidity)
- Koebner phenomenon "isomorphic response": induction of new lesion by injury
- Auspitz sign: bleeds from minute points when scale is removed
- usually non-pruritic
- exacerbating factors: drugs (lithium, ethanol, chloroquine, beta-blockers), stress
- sites: scalp, extensor surfaces of elbows and knees, trunk, nails, pressure areas

Pathophysiology

- decreased epidermal transit time from stratum basale to stratum corneum
- shortened cell cycle of psoriatic compared to normal skin
- TH1-mediated inflammatory response

Management

- preventative measures
 - avoid sunburns
 - avoid drugs that exacerbate the condition (e.g. beta-blockers, lithium, corticosteroid rebound phenomenon, interferon)
- first-line treatment
 - mainly topical, usually prescribed if less than 5-10% of total body surface area is involved
 - first-line topical treatments include moderate to potent steroids, vitamin D analogues, retinoids, anthralin, coal tar, salicylic acid
 - if the affected area is >10%, use topical medications as adjuncts to phototherapy or systemic drugs
- second-line treatment
 - include cyclosporin, methotrexate, acitretin, phototherapy
- third-line treatment
 - biologics including alefacept, etanercept, infliximab, adalimumab, ustekinumab
- systemic treatments should be considered if:
 - psoriatic lesions cover >10% of total body surface area
 - unsuccessful topical therapies
 - psychological distress

Table 11. Topical Treatment of Psoriasis

Treatment	Mechanism	Comments
Lubricants	Reduce fissure formation	Petrolatum is effective
Salicylic acid 1-12%	Remove scales	
Tar (LCD: Liquor carbonis detergens) 20% coal tar solution	Inhibits DNA synthesis, increases cell turnover	Poor long term compliance
Calcipotriene (Dovonex [®] , Dovobet [®])	Binds to skin 1,25-dihydroxyvitamin D3 to inhibit keratinocyte proliferation	Not to be used on face or skin folds
Corticosteroid ointment	Reduce scaling and thickness	Use appropriate potency steroid in different areas for degree of psoriasis
Tazarotene (Tazorac [®]) (gel/cream)	Retinoid derivative	Use on nails

Table 12. Systemic Treatment of Psoriasis

Treatment	Adverse Effects
Methotrexate	Bone marrow toxicity, hepatic cirrhosis
Psoralens and long wave ultraviolet radiation (PUVA)	Pruritus, burning, cataracts, skin cancer
Acitretin	Alopecia, cheilitis, teratogenicity, epistaxis, xerosis, hypertriglyceridemia
Cyclosporine	Renal toxicity, hypertension, immunosuppression
UVB and "Narrow band" UVB (311-312 nm)	Well tolerated

Table 13. "Biologics" approved in Canada

Treatment	Route	Dosing Schedule	Effectiveness	Action
alefacept (Amevive [®])	IM	Weekly	+	T-cell
etanercept (Enbrel [®])*	SC	Twice weekly initially	+++	TNF
adalimumab (Humira [®])*	SC	Once every 2 weeks	++++	TNF
infliximab (Remicade [®])*	IV	~Every 2 months	+++++	TNF
ustekinumab (Stelara [®])	SC	Every 12 weeks during maintenance	++++	IL 12/23

*Can also be used to treat psoriatic arthritis

PSORIASIS: Triggers

Physical trauma (Koebner's phenomenon)
Infections (acute streptococcal infection precipitates guttate psoriasis)
Stress (can be a major factor in flares)
Drugs (systemic glucocorticoids, oral lithium, antimalarial drugs, interferon)
Alcohol ingestion

Topical Treatments for Chronic Plaque Psoriasis

Cochrane Database of Systematic Reviews 2009, Issue 2

Study: Systematic review of randomized trials comparing treatments against placebo or against vitamin D.

Patients: 21,448 patients with chronic plaque psoriasis.

Intervention: Corticosteroids, dithranol, tarazotene, salicylic acid, retinoids, methotrexate, macrolactams, vitamin D, and vitamin D + corticosteroids.

Outcome: Investigator assessment of overall global improvement. Total severity scores. Psoriasis area and severity index. Patient assessment of overall global improvement.

Results: Corticosteroids, vitamin D, dithranol, and tarazotene performed better than placebo alone. A combination of corticosteroids and vitamin D were better than either vitamin D or corticosteroids alone.

Calcipotriol is a vitamin D derivative

Dovobet[®] = calcipotriene combined with betamethasone dipropionate and is considered to be the most potent topical psoriatic therapy.

Mechanism of Biologics

"-mab" = monoclonal antibody
"-cept" = receptor

2. GUTTATE PSORIASIS ("DROP-LIKE")

Clinical Presentation

- discrete, scattered salmon-pink scaling papules
- sites: generalized, sparing palms and soles
- often antecedent streptococcal pharyngitis

Management

- UVB phototherapy, sunlight, lubricants
- penicillin V or erythromycin if Group A beta-hemolytic *Streptococcus* on throat culture

3. ERYTHRODERMIC PSORIASIS

Clinical Presentation

- generalized erythema with fine desquamative scale on surface
- associated symptoms: arthralgia, severe pruritus
- may present in patient with previous mild plaque psoriasis
- aggravating factors: lithium, beta-blockers, NSAIDs, antimalarials, phototoxic reaction, infection

Management

- hospitalization, bedrest, IV fluids, monitor fluid and electrolytes
- treat underlying aggravating condition, sun avoidance
- methotrexate, cyclosporine, UV, oral retinoids, biologics

4. PUSTULAR PSORIASIS

Clinical Presentation

- sudden onset of erythematous macules and papules which evolve rapidly into pustules, very painful
- can be generalized or localized to palms/soles
- patient usually has history of psoriasis; may occur with sudden withdrawal from steroid therapy

Management

- methotrexate, oral retinoids, biologics

5. PSORIATIC ARTHRITIS

- 5 categories
 - asymmetric oligoarthritis
 - distal interphalangeal (DIP) joint involvement (predominant)
 - rheumatoid pattern (symmetric polyarthropathy)
 - psoriatic arthritis mutilans (most severe form)
 - predominant spondylitis or sacroiliitis
- see [Rheumatology, RH21](#)

Vesiculobullous Diseases

Bullous Pemphigoid

Clinical Presentation

- chronic autoimmune bullous eruption characterized by pruritic, tense, subepidermal bullae on an erythematous or normal skin base
- sites: flexor aspect of forearms, axillae, medial thighs, groin, abdomen, mouth (33%)

Pathophysiology

- IgG produced against dermal-epidermal basement membrane proteins (hemidesmosomes) leads to subepidermal bullae

Epidemiology

- 60-80 years old
- associated with malignancy (rarely)

Investigations

- immunofluorescence shows deposition of IgG and C3 in the basement membrane
- anti-basement membrane antibody (IgG) (pemphigoid antibody detectable in serum)

Prognosis

- generalized bullous eruption heals without scarring
- rarely fatal

Pemphigus Vulgaris vs. Bullous Pemphigoid

Vulgaris = Superficial, intraepidermal, flaccid lesions
Pemphigoid = Deeper, tense lesions at the dermal-epidermal junction

Management

- prednisone \pm steroid-sparing agents (e.g. azathioprine)
- topical potent steroids (clobetasol) may be as effective as systemic steroids
- tetracycline \pm nicotinamide is effective for some cases
- dapsone for milder cases

Dermatitis Herpetiformis**Clinical Presentation**

- grouped papules/vesicles/urticarial wheals on an erythematous base, associated with intense pruritus, burning, stinging
- almost always excoriated, rarely seen as blisters
- lesions grouped, bilaterally symmetrical
- sites: extensor surfaces of elbows/knees, sacrum, buttocks, scalp

Pathophysiology

- 90% have HLA B8, DR3, DQWZ
- 90% associated with gluten-sensitive enteropathy (celiac) (80% are asymptomatic)
- 30% have thyroid disease; some have intestinal lymphoma or iron/folate deficiency

Epidemiology

- 20-60 years old, M:F = 2:1

Management

- dapsone for pruritus
- gluten-free diet

Pemphigus Vulgaris**Clinical Presentation**

- autoimmune blistering disease characterized by flaccid, non-pruritic epidermal bullae/vesicles on an erythematous or normal skin base
- may present with erosions and secondary bacterial infection
- sites: mouth (90%), scalp, face, chest, axillae, groin, umbilicus
- Nikolsky's sign: sliding or rubbing pressure on skin \rightarrow separation of epidermis
- Asboe-Hansen sign: pressure applied to bulla causes it to extend laterally

Pathophysiology

- IgG produced against epidermal desmoglein 1 and 3 leads to intraepidermal bullae

Epidemiology

- 40-60 years old, higher prevalence in Jewish, Mediterranean, Asian populations
- paraneoplastic pemphigus may be associated with thymoma, myasthenia gravis, malignancy, and use of D-penicillamine

Investigations

- immunofluorescence: shows IgG and C3 deposition intraepidermally
- circulating serum anti-desmoglein IgG antibodies

Prognosis and Clinical Course

- begins with mouth lesions, followed by skin lesions
- first localized (6-12 months) then generalized
- lesions heal with hyperpigmentation but no scar
- may be fatal unless treated with immunosuppressive agents

Management

- prednisone 1.0-3.0 mg/kg until no new blisters, then 1.0-1.5 mg/kg until clear, then taper
- steroid-sparing agents: azathioprine, methotrexate, gold, cyclophosphamide, cyclosporine, intravenous immunoglobulin (IVIG), mycophenolate mofetil
- plasmapheresis for acutely high antibody levels

**Pemphigus Foliaceus**

An autoimmune intraepidermal blistering disease that is more superficial than pemphigus vulgaris due to antibodies against desmoglein 1, an intracellular adhesion molecule. Appears as crusted patches and erosions which can initially be managed with topical steroids if localized. Active widespread disease is treated like pemphigus vulgaris.

**Azathioprine**

Thiopurine methyltransferase (TPMT) levels should be measured before starting therapy. Individuals with low enzyme activity will experience greater immunosuppression.

Table 14. Summary of Vesiculobullous Diseases

	Bullous Pemphigoid	Dermatitis Herpetiformis	Pemphigus Vulgaris
Antibody	IgG	IgA	IgG
Site	Basement membrane	Dermal	Intraepidermal
Infiltrate	Eosinophils	Neutrophils	Eosinophils and neutrophils
Management	Systemic steroids Immunosuppressive agents Tetracycline Clobetasol cream	Gluten-free diet Dapsone	High dose steroids Immunosuppressive agent (e.g. Imuran®, mycophenolic acid)
Association	Malignancy (rarely)	Gluten enteropathy Thyroid disease Intestinal lymphoma	Malignancy with paraneoplastic pemphigus

Porphyria Cutanea Tarda

Clinical Presentation

- tense vesicles/bullae in photoexposed areas subjected to trauma
- facial hypertrichosis, brown hypermelanosis vesicles, and bullae in photodistribution (dorsum of hands and feet)
- sites: light-exposed areas subjected to trauma, dorsum of hands and feet, nose, and upper trunk

Pathophysiology

- autosomal dominant or sporadic skin disorder associated with the presence of excess heme
- associated with alcohol abuse, DM, drugs (estrogen therapy, NSAIDs), HIV, hepatitis C, increased iron indices

Epidemiology

- 30-40 years old, M>F

Investigations

- urine + 5% HCl shows orange-red fluorescence under Wood's lamp (UV rays)
- 24-hour urine for uroporphyrins (elevated)
- stool contains elevated coproporphyrins
- immunofluorescence shows IgE at dermal-epidermal junctions

Management

- discontinue aggravating substances (alcohol, estrogen therapy)
- phlebotomy to decrease body iron load
- low dose hydroxychloroquine

Drug Eruptions

Drug Hypersensitivity Syndrome

- fever followed by symmetrical bright red exanthematous eruption that may lead to internal organ involvement (hepatitis, arthralgia, nephritis, pneumonitis, lymphadenopathy, and/or hematologic abnormalities)
- classically occurs approximately 10 days after first exposure to the drug
- siblings at risk
- most common causes: sulfonamides and anticonvulsants (phenytoin, phenobarbital, carbamazepine, lamotrigine)
- 10% mortality if undiagnosed and untreated

Erythema Multiforme (EM), Stevens-Johnson Syndrome (SJS), Toxic Epidermal Necrolysis (TEN)

- disorders with varying presence of characteristic skin lesions, blistering and mucous membrane involvement
- NOTE: EM is considered to be distinct from the SJS-TEN spectrum

Drug Hypersensitivity Syndrome Triad
Fever
Exanthematous Eruption
Internal Organ Involvement

Table 15. Comparison of Erythema Multiforme, Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis

	Erythema Multiforme (EM)	Stevens-Johnson Syndrome (SJS)	Toxic Epidermal Necrolysis (TEN)
Lesion	Macules/papules with central vesicles Classic bull's-eye pattern of concentric light and dark rings (target lesions) Bilateral and symmetric All lesions appear within 72 hours No edema Lesion "fixed" for at least 7 days	EM with more mucous membrane involvement "Atypical lesions": red circular patch with dark purple centre "Sicker" (high fever) Sheet-like epidermal detachment in <10% (Nikolsky sign)	Severe mucous membrane involvement, and blistering "Atypical lesions": 50% have no target lesions Diffuse erythema then necrosis and sheet-like epidermal detachment in >30%
Sites	Dorsa of hands and forearms Mucous membrane involvement (lips, tongue, buccal mucosa) is possible Extremities with face > trunk Involvement of palms and soles	Generalized with prominent face and trunk involvement Palms and soles may be spared	Generalized Nails may also shed
Other Complications	Burning and stinging Recurrences Secondary bacterial infection	Scarring, contractures, eruptive nevocmelanocytic nevi, corneal scarring, blindness, phimosis and vaginal synechiae	Tubular necrosis and acute renal failure, epithelial erosions of trachea
Constitutional Symptoms	Weakness, malaise	Prodrome 1-14 days prior to eruption with fever and flu-like illness	High fever >38°C
Etiology	Infection: HSV, or <i>Mycoplasma pneumoniae</i>	15% are drug-related (NSAIDs, anticonvulsants, sulfonamides, penicillins) Occurs up to 1-3 weeks after drug exposure with more rapid onset upon rechallenge	50% are definitely drug related <5% are due to viral infection, immunization
Differential Diagnosis	Giant urticaria, granuloma annulare, mycosis fungoides, vasculitis	Scarlet fever, phototoxic, eruption, graft vs. host disease (GVHD), staphylococcal scalded skin syndrome (SSSS), exfoliative dermatitis, Kawasaki disease, paraneoplastic pemphigus	Scarlet fever, phototoxic eruption, GVHD, SSSS, exfoliative dermatitis
Course and Prognosis	Lesions last 2 weeks and heal without complications	4-6 week course 5% mortality	30% mortality due to fluid loss, regrowth of epidermis by 3 weeks, secondary infection
Management	Symptomatic treatment (oral antihistamines, oral antacids) Corticosteroids in severely ill (controversial) Prophylactic oral acyclovir for 6-12 months for herpes simplex virus (HSV)-associated EM with frequent recurrences	Prolonged hospitalization Withdraw suspect drug Intravenous fluids Corticosteroids (controversial) Infection prophylaxis Consider IVIG	As for Stevens-Johnson syndrome Admit to burn unit Debride frankly necrotic tissue Consider IVIG

Erythema multiforme is a clinical diagnosis. Reasonable evidence exists for the following as precipitating factors:

- HSV (predominant precipitating factor)
- *Mycoplasma pneumoniae*
- Orf virus

SCORTEN: A Severity-of-Illness Score for Toxic Epidermal Necrolysis

J Invest Dermatol 2000;115:149-153

Study: Develop and validate a specific severity-of-illness score for cases of TEN and compare to Simplified Acute Physiology Score and burn scoring system.

Patients: To develop score and evaluate other scores: 165 patients with SJS, SJS/TEN, or TEN admitted to the ICU. For validation, a separate database of 75 patients were used.

Outcome: Agreement between expected and actual mortality. Powers of discrimination.

Results: Seven different risk factors for death: age >40 y, malignancy, tachycardia above 120, initial epidermal detachment >10%, serum urea >10 mmol/L, serum glc >14 mmol/L, and bicarb <20 mmol/L. Expected score correlated with actual mortality (19.2% compared to 20%); whereas, the SAPS had poor agreement between expected and actual mortality (9.1% vs. 26.7%)

Exanthematous Eruptions (Maculopapular Eruptions/Morbilliform)

- symmetrical, widespread, erythematous patches or plaques ± scales
- the "classic" and most common adverse drug reaction
- often starts on trunk or areas of sun exposure
- may progress to generalized exfoliative dermatitis especially if the drug is continued
- most common causes: penicillin > sulfonamides > phenytoin
- see *Pediatric Exanthems*, D40

Fixed Drug Eruption

- sharply demarcated erythematous oval patches on the skin or mucous membranes
 - sites: face, mucosa, genitalia
 - reoccurs in same location upon subsequent exposure to the drug (fixed location)
- most common causes: antimicrobials (tetracycline, sulfonamides), anti-inflammatories, psychoactive agents (barbiturates), phenolphthalein

Photosensitivity Eruptions

- phototoxic reaction: “an exaggerated sunburn” confined to sun-exposed areas
- photoallergic reaction: an eczematous eruption that may spread to areas not exposed to light
- most common causes: chlorpromazine, doxycycline, thiazide diuretics, procainamide

Serum Sickness-Like Reaction

- a symmetric drug eruption resulting in fever, arthralgia, lymphadenopathy, and skin rash
- usually appears 5-10 days after drug
- skin manifestations: usually urticaria; can be morbilliform
- most common causes: cefaclor in kids; bupropion (Zyban®) in adults

Heritable Disorders

Ichthyosis Vulgaris

Clinical Presentation

- generalized hyperkeratosis leading to dry skin
- “fish-scale” appearance especially on extremities with sparing of flexural creases, palms and soles; scaling without inflammation

Pathophysiology

- abnormal retention of hyperkeratosis
- scaling without inflammation

Epidemiology

- 1:300 incidence
- autosomal dominant inheritance
- associated with atopic dermatitis and keratosis pilaris

Management

- immersion in bath and oils
- emollient or humectant creams, and creams or oils containing urea

Neurofibromatosis (Type I; von Recklinghausen’s Disease)

Clinical Presentation

- diagnostic criteria includes 2 or more of the following:
 1. more than 6 café-au-lait spots >1.5 cm in an adult, and more than 5 café-au-lait spots >0.5 cm in a child under age 5
 2. axillary or inguinal freckling
 3. iris hamartomas (Lisch nodules)
 4. optic gliomas
 5. neurofibromas
 6. distinctive bony lesion
 7. first degree relative with neurofibromatosis type 1
- associated with pheochromocytoma, astrocytoma, bilateral acoustic neuromas, bone cysts, scoliosis, precocious puberty, developmental delay, and renal artery stenosis

Pathophysiology

- autosomal dominant disorder with excessive and abnormal proliferation of neural crest elements (Schwann cells, melanocytes)
- linked to absence of neurofibromin (a tumour suppressor gene)

Epidemiology

- incidence 1:3,000

Management

- follow closely for malignancy, transformation of neurofibroma to neurofibrosarcoma
- excise suspicious or painful lesions
- see [Pediatrics](#), P86

Vitiligo

Clinical Presentation

- primary pigmentary disorder characterized by hypopigmentation and depigmentation
- acquired destruction of melanocytes characterized by sharply margined white patches
- associated with streaks of depigmented hair, chorioretinitis
- sites: extensor surfaces and periorificial areas (mouth, eyes, anus, genitalia)
- Koebner phenomenon "isomorphic response": may be precipitated by trauma

Pathophysiology

- acquired autoimmune destruction of melanocytes

Epidemiology

- 1% incidence, polygenic
- 30% with positive family history

Investigations

- rule out associated autoimmune diseases: thyroid disease, pernicious anemia, Addison's disease, Type I DM
- Wood's lamp to detect lesions: illuminates UV light onto skin to detect patches of amelanosis

Management

- sun avoidance and protection
- topical immunomodulator (i.e. tacrolimus, pimecrolimus) or a topical steroid for 6-12 months prior to attempting phototherapy
- PUVA
- camouflage preparations
- "bleaching" normal pigmented areas (i.e. hydroquinone 20%) if widespread loss of pigmentation

Interventions for Vitiligo

Cochrane Database of Syst Rev 2010; Issue 1

Study: Systematic review of randomized controlled trials.

Patients: 3139 participants with vitiligo.

Intervention: Topical treatments, light therapies, oral treatments, surgical methods, and psychological therapies

Outcome: >75% repigmentation, adverse effects

Results: Moderate evidence exists for the use of topical corticosteroids to induce repigmentation. However, adverse effects are observed with long-term use. Topical use of non-steroidal immunomodulators (i.e. tacrolimus), especially in combination with light therapies, has also been shown to induce repigmentation. However, long-term use may theoretically increase the risk for skin cancer. In general, combination therapy including some form of light therapy had the most significant improvement. Sustained repigmentation (>2 years) has not been reported and thus results should be treated with caution.

Randomized Double-blind Trial of Treatment of Vitiligo

Arch Dermatol 2007; 143: 578

Study: Double-blinded randomized study.

Patients: 56 patients with nonsegmental vitiligo.

Interventions: PUVA or NB-UVB twice per week

Outcome: % of body surface area that was repigmented and colour match compared to unaffected skin at 48 sessions of therapy, at the end of therapy, and at 12 months.

Results: NB-UVB is superior to PUVA. 64% of 25 patients in the NB-UVB group showed greater than 50% improvement in BSA compared to 36% of 25 patients in the PUVA group. Colour match was greater in the NB-UVB group than the PUVA group ($P < 0.001$). After 48 sessions BSA change was greater in the NB-UVB group ($P = .007$) this benefit was maintained at 12 months.

Infections

Bacterial Infections

- often involve the epidermis, dermis, hair follicles or periungual region ± systemic

SUPERFICIAL SKIN (EPIDERMAL)

Table 16. Comparison of Impetigo Vulgaris and Bullous Impetigo

	Impetigo Vulgaris	Bullous Impetigo
Clinical Presentation	Acute purulent infection which appears vesicular; progresses to golden yellow "honey-crusted" lesions surrounded by erythema Sites: commonly face, arms, legs and buttocks	Scattered, thin-walled bullae containing clear yellow or slightly turbid fluid with no surrounding erythema Sites: trunk, intertriginous areas, face
Etiology	Group A beta-hemolytic <i>Streptococcus</i> (GAS), <i>S. aureus</i> , or both	<i>S. aureus</i> group II elaborating exfoliating toxin
Epidemiology	Preschool and young adults living in crowded conditions, poor hygiene, neglected minor trauma	Neonates and older children, can be epidemic
Differential Diagnosis	Infected eczema, HSV, varicella virus	Bullous drug eruption, pemphigus vulgaris, bullous insect bites, thermal burns
Investigations	Gram stain and culture of lesion fluid or biopsy	Same as impetigo vulgaris
Management	Remove crusts, use saline compresses and topical antiseptic soaks bid Topical antibacterials such as 2% mupirocin or fusidic acid TID; continue for 7-10 days after resolution Systemic antibiotics such as cloxacillin or cephalixin for 7-10 days	Cloxacillin for 7-10 days Topical antibacterials such as fusidic acid or mupirocin; continue for 7-10 days after oral antibiotic is stopped Complication: high levels of toxin in immunocompromised or young children may lead to generalized skin peeling or staphylococcal scalded skin syndrome (SSSS)

DEEPER SKIN (DERMAL)

Table 17. Comparison of Erysipelas and Cellulitis

	Erysipelas	Cellulitis
Clinical Presentation	Involves upper dermis Confluent, erythematous, raised, warm plaque, well demarcated Very painful (once called St. Anthony's fire) Sites: face and legs Systemic symptoms: fever, chills, headache, weakness (if present, sign of more serious infection)	Involves lower dermis/subcutaneous fat Unilateral erythematous flat lesion, often with vesicles poorly demarcated, not uniformly raised Tender Sites: commonly on legs Systemic symptoms (uncommon): fever, leukocytosis, lymphadenopathy
Etiology	GAS	GAS, <i>S. aureus</i> (large sized wounds), <i>H. influenzae</i> (periocular), <i>Pasteurella multocida</i> (dog/cat bite)
Complications	Scarlet fever, streptococcal gangrene, fat necrosis, coagulopathy Spreads via lymphatics	Uncommon
Differential Diagnosis	DVT (less red, less hot, smoother), superficial phlebitis, contact dermatitis, photosensitivity reaction, stasis dermatitis, panniculitis, vasculitis	Same as erysipelas
Investigations	Clinical diagnosis: rarely do skin/blood culture If suspect necrotizing fasciitis: do immediate biopsy and frozen section, histopathology	Same as erysipelas
Management	1st line: penicillin, cloxacillin or cefazolin 2nd line: clindamycin or cephalexin If allergic to penicillin use erythromycin	1st line: cloxacillin or cefazolin/cephalexin 2nd line: erythromycin or clindamycin Children: cefuroxime If diabetes mellitus (foot infections): trimethoprim-sulfamethoxazole (TMP/SMX) and metronidazole

COMMON HAIR FOLLICLE INFECTIONS

Table 18. Comparison of Superficial Folliculitis, Furuncles and Carbuncles

	Superficial Folliculitis	Furuncles (Boils)	Carbuncles
Clinical Presentation	Superficial infection of the hair follicle (versus pseudofolliculitis: inflammation of follicle due to friction, irritation, or occlusion) Acute lesion consists of a dome-shaped pustule at the mouth of hair follicle Pustule ruptures to form a small crust Sites: primarily scalp, shoulders, anterior chest, upper back, other hairbearing areas	Red, hot, tender, inflammatory nodules with central yellowish point, which forms over summit and ruptures Involves subcutaneous tissue that arises from a hair follicle Sites: hair-bearing skin (thigh, neck, face, axillae, perineum, buttocks)	Deep-seated abscess formed by multiple coalescing furuncles Usually in areas of thicker skin Occasionally ulcerates Lesions drain through multiple openings to the surface Systemic symptoms may be associated
Etiology	Normal non-pathogenic bacteria (<i>Staphylococcus</i> – most common; <i>Pseudomonas</i> – hot tub) <i>Pityrosporum</i>	<i>S. aureus</i>	<i>S. aureus</i>
Management	Antiseptic (Hibitane®) Topical antibacterial (fusidic acid, mupirocin, or erythromycin) Oral cloxacillin for 7-10 days	Incise and drain large carbuncles to relieve pressure and pain If afebrile: hot wet packs, topical antibiotic If febrile/cellulitis: culture blood and aspirate pustules (Gram stain and C&S) Cloxacillin for 1-2 weeks (especially for lesions near external auditory canal/nose, with surrounding cellulitis, and not responsive to topical therapy)	Same as for furuncles

Dermatophytoses

Clinical Presentation

- infection of skin, hair and nails caused by dermatophytes (fungi that live within the epidermal keratin and do not penetrate deeper structures)

Pathophysiology

- digestion of keratin by dermatophytes results in scaly skin, broken hairs, crumbling nails

Etiology

- Trichophyton*, *Microsporum*, *Epidermophyton* species (*Pityrosporum* is a superficial yeast)

Investigations

- skin scrapings, hair, and/or nail clippings analyzed with potassium hydroxide (KOH) prep to look for hyphae and mycelia

Management

- topicals as first line agents for tinea corporis/cruris and tinea pedis (interdigital type):
 - e.g. clotrimazole or terbinafine cream applied OD or BID, until one week after complete resolution of lesions
- oral therapy is indicated for onychomycosis or tinea capitis:
 - e.g. terbinafine (Lamisil® – liver toxicity, CYP 2D6 inhibitor) or itraconazole (Sporanox® – heart failure reported, CYP 3A4 inhibitor)

Table 19. Different Manifestations of Dermatophyte Infection

	Clinical Presentation	Differential Diagnosis	Investigations	Management
Tinea Capitis	Round, scaly patches of alopecia, possibly with broken off hairs; pruritic Sites: scalp, eyelashes, and eyebrows; involving hair shafts and follicles Kerion (boggy, elevated, purulent inflamed nodule/plaque) may form secondary to infection by bacteria and result in scarring May have occipital lymphadenopathy Affects children (mainly black), immunocompromised adults Very contagious and may be transmitted from barber, hats, theatre seats, pets	Alopecia areata, psoriasis, seborrheic dermatitis, trichotillomania	Wood's light examination of hair: green fluorescence only for <i>Microsporum</i> infection Culture of scales/hair shaft Microscopic examination of KOH preparation of scales or hair shafts	Griseofulvin x 8 weeks or terbinafine (Lamisil®) x 2-4 weeks NB: oral agents are required to penetrate the hair root Adjunctive antifungal shampoos or lotions may be helpful (e.g. selenium sulfide, ketoconazole, ciclopirox)
Tinea Corporis (Ringworm)	Pruritic, scaly, round/oval plaque with active erythematous margin and central clearing Site: trunk, limbs, face	Granuloma annulare, pityriasis rosea, psoriasis, seborrheic dermatitis	Microscopic examinations of KOH prep of scales shows hyphae Culture of scales	Topicals: 1% clotrimazole or 2% miconazole BID for 2-4 weeks
Tinea Cruris ("Jock Itch")	Scaly patch/plaque with a well-defined, curved border and central clearing Pruritic, erythematous, dry/macerated Site: medial thigh	Candidiasis (involvement of scrotum and satellite lesions), contact dermatitis, erythrasma	Same as for tinea corporis	Topicals: 1% clotrimazole or 2% miconazole BID for 2-4 weeks
Tinea Pedis (Athlete's Foot)	Pruritic scaling and/or maceration of the web spaces and powdery scaling of soles Acute infection: interdigital (esp. 4th web space) red/white scales, vesicles, bullae, often with maceration Secondary bacterial infection is common Chronic: non-pruritic, pink, scaling keratosis on soles and sides of feet May present as flare-up of chronic tinea pedis Predisposing factors: heat, humidity, occlusive footwear	Atopic dermatitis, contact dermatitis, dyshidrotic dermatitis, erythrasma, intertrigo (interdigital), psoriasis	Same as for tinea corporis	Topicals: 1% clotrimazole or 2% miconazole BID for 2-4 weeks
Tinea Manuum	Primary fungal infection of the hand is rare; usually associated with tinea pedis Acute: blisters at edge of red areas on hands Chronic: single dry scaly patch	Atopic dermatitis, contact dermatitis, granuloma annulare, psoriasis	Same as for tinea corporis	Topicals: 1% clotrimazole or 2% miconazole BID for 2-4 weeks
Tinea Unguium (Onychomycosis)	Crumbling, distally dystrophic nails; yellowish, opaque with subungual hyperkeratotic debris Toenail infections usually precede fingernail infections <i>T. rubrum</i> (90% of all toenail infections)	Psoriasis, lichen planus, contact dermatitis, traumatic onychodystrophies, bacterial infections	Microscopic examinations of KOH prep of scales from subungual scraping shows hyphae Culture of subungual scraping or nail clippings on Sabouraud's agar	Terbinafine (Lamisil®) (6 weeks for fingernails, 12 weeks for toenails) Itraconazole (Sporanox®) 7 days on, 3 weeks off (2 pulses for fingernails, 3 pulses for toenails) Topical: ciclopirox (Penlac®); nail laquer

Parasitic Infections

SCABIES

Clinical Presentation

- a transmissible parasitic skin infection due to *Sarcoptes scabiei*, a mite, characterized by superficial burrows, intense pruritus (especially nocturnal), and secondary infection
- primary lesion: superficial linear burrows
- secondary lesion: small urticarial crusted papules, eczematous plaques, excoriations
- sites: axillae, groin, buttocks, hands/feet (especially web spaces), sparing of head and neck (except in infants)

Pathogenesis

- scabies mite remains alive 2-3 days on clothing/sheets
- incubation of 1 month, then pruritus begins
- re-infection followed by hypersensitivity in 24 hours

Etiology

- *Sarcoptes scabiei*, a mite
- risk factors: sexual promiscuity, crowding, poverty, nosocomial, immunocompromised

Differential Diagnosis

- asteatotic eczema, dermatitis herpetiformis (vesicles, urticaria, eosinophilia, no burrows), lichen simplex chronicus (neurodermatitis)

Investigations

- microscopic examination of root and content of burrow with KOH for mite, eggs, feces

Management

- bathe, then apply permethrin 5% cream (i.e. Nix®) from neck down to soles of feet (must be left on for 8-14 hours and requires second treatment 7 days after first treatment)
- change underwear and linens; wash with detergent in hot water cycle then machine dry
- ± antihistamine
- treat family and contacts
- pruritus may persist for 2-3 weeks due to prolonged hypersensitivity reaction

LICE (PEDICULOSIS)**Clinical Presentation**

- intensely pruritic red excoriations, morbilliform rash, caused by louse (a parasite)
- scalp lice: nits (i.e. louse eggs) on hairs
 - red excoriated skin with secondary bacterial infection, lymphadenopathy
- pubic lice: nits on hairs
 - excoriations
- body lice: nits and lice in seams of clothing
 - excoriations and secondary infection mainly on shoulders, belt-line and buttocks

Differential Diagnosis

- bacterial infection of scalp, seborrheic dermatitis

Management

- permethrin 1% (Nix® cream rinse) (ovicidal) or permethrin 1% (RC & Cor®, Kwellada-P® shampoo)
- comb hair with fine-toothed comb using dilute vinegar solution to remove nits
- repeat in 7 days after first treatment
- change clothing and linens; wash with detergent in hot water cycle then machine dry

Viral Infections

HERPES SIMPLEX**Clinical Presentation**

- herpetiform (i.e. grouped) vesicles on an erythematous base on skin or mucous membranes
- transmitted via contact with erupted vesicles or via asymptomatic viral shedding
- **primary**
 - children and young adults
 - usually asymptomatic; may have high fever, regional lymphadenopathy, malaise
 - followed by antibody formation and latency of virus in nerve root ganglion
- **secondary**
 - recurrent form seen in adults; much more common than primary
 - prodrome: tingling, pruritus, pain
 - triggers for recurrence: fever, sunburn, physical trauma, menstruation, emotional stress, upper respiratory tract infection (URTI)
- potential complications
 - dendritic corneal ulcer
 - erythema multiforme (EM)
 - herpes simplex encephalitis
 - HSV infection on atopic dermatitis causing Kaposi's varicelliform eruption (eczema herpeticum)
- 2 biologically and immunologically different subtypes: **HSV-1** and **HSV-2**

HSV-1

- typically “cold sores” (grouped vesicles at the mucocutaneous junction which quickly burst)
- recurrent on face, lips but NOT on mucous membranes (unlike aphthous ulcers)

Management

- treat during prodrome to prevent vesicle formation
- topical antiviral (Zovirax®) cream, apply 5-6x/day, 4-7 days for facial/genital lesions
- oral antivirals are far more effective and have an easier dosing schedule

HSV-2

- sexually transmitted; incubation 2-20 days
- gingivostomatitis: entire buccal mucosa involved with erythema and edema of gingiva
- vulvovaginitis: edematous, erythematous, extremely tender, profuse vaginal discharge
- urethritis: watery discharge in males
- recurrent on vulva, vagina, penis for 5-7 days
- diagnosis
 - negative darkfield, negative serology for syphilis, negative bacterial cultures
 - Tzanck smear with Giemsa stain shows multinucleated giant epithelial cells
 - tissue culture and electron microscopy of vesicular fluid
 - skin biopsy
 - antibody titres increase one week after primary infection only (no increase with recurrent lesions)
- DDx of genital ulcers: *Candida balanitis*, chancroid, multiple syphilitic chancres

Management

- rupture vesicle with sterile needle
- wet dressing with aluminum subacetate solution, Burow's compression, or betadine solution
- 1st episode: acyclovir 200 mg PO 5 times a day x 10 days
 - maintenance: acyclovir 400 mg PO BID
- famciclovir and valacyclovir may be substituted and have better enteric absorption
- in case of herpes genitalis, look for and treat any other sexually-transmitted infections

Both HSV-1 and HSV-2 can occur on face or genitalia.

HERPES ZOSTER (SHINGLES)**Clinical Presentation**

- unilateral dermatomal eruption occurring 3-5 days after pain and paresthesia of that dermatome
- vesicles, bullae, and pustules on an erythematous, edematous base
- lesions may become eroded/ulcerated and last days – weeks
- pain is pre-herpetic, synchronous with rash, or post-herpetic
- severe post-herpetic neuralgia often occurs in elderly
- Hutchinson's sign: involvement of tip of nose suggests eye involvement
- distribution: thoracic (50%), trigeminal (10-20%), cervical (10-20%); disseminated in HIV

Herpes Zoster typically involves a single dermatome; lesions rarely cross the midline.

Etiology

- caused by varicella zoster in a person who has already had the primary infection (chicken pox)
- risk factors: immunosuppression, old age, occasionally associated with hematologic malignancy

Differential Diagnosis

- before thoracic skin lesions occur, must consider other causes of chest pain
- contact dermatitis, localized bacterial infection, zosteriform herpes simplex virus (more pathogenic for the eyes than varicella zoster)

Management

- compress with normal saline, burrow's, or betadine solution
- analgesics (NSAIDs, amitriptyline)
- for patients over 50 years old, with severe acute pain or ophthalmic involvement: famciclovir or valacyclovir for 7 days or acyclovir for 7 days if immunocompromised; must initiate within 72 hours to be of benefit
- gabapentin 300-600 mg PO TID for post-herpetic neuralgia

MOLLUSCUM CONTAGIOSUM

Clinical Presentation

- discrete dome-shaped and umbilicated pearly, white papules caused by DNA pox virus (*Molluscum contagiosum* virus (MCV))
- sites: eyelids, beard (likely spread by shaving), neck, axillae, trunk, perineum, buttocks

Etiology

- *Molluscum contagiosum* is spread via direct contact, auto-inoculation, sexual contact
- common in children and AIDS patients

Management

- topical cantharidin (a keratolytic)
- liquid nitrogen cryotherapy
- curettage
- Aldara® (imiquimod): immune modulator that produces a cytokine inflammation

WARTS (VERRUCA VULGARIS) (HUMAN PAPILLOMA VIRUS (HPV) INFECTIONS)

Table 20. Different Manifestations of HPV Infection

	Definition and Clinical Features	Differential Diagnosis
Verruca Vulgaris (Common Warts)	Hyperkeratotic, elevated discrete epithelial growths with papillated surface caused by HPV – at least 80 types are known Located at trauma sites: fingers, hands, knees of children and teens Paring of surface reveals punctate, red-brown specks (dilated capillaries)	Molluscum contagiosum, seborrheic keratosis
Verruca Plantaris (Plantar Warts) and Verruca Palmaris (Palmar Warts)	Hyperkeratotic, shiny, sharply marginated growths Commonly HPV 1, 2, 4, 10 Located at pressure sites: heads of metatarsal, heels, toes Paring of surface reveals red-brown specks (capillaries), interruption of epidermal ridges	Need to scrape (“pare”) lesions to differentiate wart from callus and corn (see side bar D8)
Verruca Planae (Flat Warts)	Multiple discrete, skin coloured, flat topped papules grouped or in linear configuration Common in children Commonly HPV 3, 10 Sites: face, dorsa of hands, shins, knees	Syringoma, seborrheic keratosis, molluscum contagiosum, lichen planus
Condyloma Acuminata (Genital Warts)	Skin-coloured pinhead papules to soft cauliflower like masses in clusters Commonly HPV 6 and 11 HPV 16, 18, 31, 33 cause cervical dysplasia, squamous cell cancer and invasive cancer Sites: genitalia and perianal areas Often occurs in young adults, infants, children Can be asymptomatic, lasting months to years Highly contagious, transmitted sexually and non-sexually (e.g. Koebner phenomenon via scratching, shaving), and can spread without clinically apparent lesions Investigations: acetowhitening (subclinical lesions seen with 5% acetic acid x 5 minutes and hand lens) Complications: fairy-ring warts (satellite warts at periphery of treated area of original warts)	Condyloma lata (secondary syphilitic lesion, darkfield strongly +ve), Molluscum contagiosum

Table 21. Management of Warts

Management	Type of Wart	Notes
Destructive		
Liquid nitrogen/electrodesiccation	All	Dyschromia, pain, 10-30 seconds
Surgery	Resistant	Scar, recurrence
Laser	Resistant	CO ₂ and Nd: Yag lasers
Caustic Acids		
Cantharidin (topical)	Small, common	Keratolytic irritation, blisters, hyperpigmentation
Mono-, di-, or tri-chloroacetic acid	Common	Irritation, blisters, scar
Chemotherapeutic Agents		
Podophyllotoxin*	Genital	Erythema, erosions, ulcers, pain
Bleomycin (intralesional)*	Common	Pain, nail loss/dystrophy, Raynaud's phenomenon
Hypersensitivity Agents		
Dinitrochlorobenzene (DNCB)	Common, plantar	Causes an allergic/hypersensitivity reaction
Immune Response Modifiers	Genital	Erythema, burning, erosion
5% imiquimod cream (Aldara®)*	All	
Miscellaneous		
No treatment	Common	65-90% resolve spontaneously over several years
Salicylic acid 40% minimum	Common, plantar	Over the counter (OTC), use with occlusion
Tretinoin (topical)*	Flat	Irritation
Cimetidine (oral)*	Resistant	Best in children
Canthone plus	Common, plantar	Cantharidin + podophyllin + salicylic acid
Duct tape		
± occlusion/callous scraping/paring		

*Avoid in pregnancy

Yeast Infections

CANDIDIASIS

Candidal Paronychia

- painful red swellings of periungual skin
- management: topical agents not as effective; oral antifungals recommended

Candidal Intertrigo

- macerated/eroded erythematous patches that may be covered with papules and pustules, located in intertriginous areas often under breast, groin, or interdigitally
- peripheral "satellite" pustules
- predisposing factors: obesity, diabetes, systemic antibiotics, immunosuppression, malignancy
- starts as non-infectious maceration from heat, moisture and friction
- management: keep area dry, miconazole, ketoconazole/clotrimazole cream bid until rash clears

PITYRIASIS (TINEA) VERSICOLOUR

Clinical Presentation

- chronic asymptomatic superficial fungal infection with brown/white scaling macules
- affected skin darker than surrounding skin in winter, lighter in summer (does not tan)
- sites: upper trunk most common

Pathophysiology

- microbe produces carboxylic acid → inflammatory reaction inhibiting melanin synthesis yielding variable pigmentation
- affinity for sebaceous glands; require fatty acids to survive

Etiology

- *Pityrosporum ovale* (*Malassezia furfur*)
- also associated with folliculitis and seborrheic dermatitis
- predisposing factors: summer, tropical climates, Cushing's syndrome, prolonged corticosteroid use

Investigations

- microscopic examination KOH prep of scales for hyphae and spores

Management

- scrub off scales with soap and water
- selenium sulfide body lotion
- ketoconazole cream or PO daily for 10 days if more extensive

Treatment for Skin Warts

First Line Therapies

Salicylic acid preparations (patches, solutions, creams, ointments)
Silver nitrate stick
Topical cantharone
Glutaraldehyde
Occlusive methods (duct tape)

Second Line Therapies

Liquid nitrogen cryotherapy
Topical imiquimod

Third Line Therapies

Curettage
Cautery
Surgery
Laser
Oral cimetidine (particularly children)
Topical 5-fluorouracil
Topical tretinoin (flat warts)
Localized heat therapy
Intralesional bleomycin (plantar warts)

Treatment for Anogenital Warts

First line therapies

Imiquimod 5% cream
Podophyllotoxin (solution, cream, or gel)
Podophyllin resin
Cryotherapy

Second line therapies

Trichloroacetic acid
Topical 5-fluorouracil
Electrodesiccation
Surgical excision (with cold steel or scissors)
CO₂ laser

Oral Terbinafine (Lamisil®) is not effective because it is not secreted by sebaceous glands.

Sexually Transmitted Infections

SYPHILIS

Clinical Presentation

- characterized initially by a painless ulcer (chancre)
- following inoculation, systemic infection with secondary and tertiary stages

Etiology

- *Treponema pallidum*
- transmitted sexually, congenitally, or rarely by transfusion

Table 22. Stages of Syphilis

	Primary Syphilis	Secondary Syphilis	Tertiary Syphilis
Clinical Presentation	<ul style="list-style-type: none"> • Single red, indurated, painless chancre, that develops into painless ulcer with raised border and scanty serous exudate • Chancre develops at site of inoculation after 3 weeks of incubation and heals in 4-6 weeks; chancre may also develop on lips or anus • Regional non-tender lymphadenopathy appears <1 week after onset of chancre • DDx: chancroid (painful), HSV (multiple lesions) 	<ul style="list-style-type: none"> • Presents 2-6 months after primary infection (patient may not recall presence of primary chancre) • Associated with generalized lymphadenopathy, splenomegaly, headache, chills, fever, arthralgias, myalgias, malaise, photophobia • Lesions heal in 1-5 weeks and may recur for 1 year • 3 types of lesions: <ol style="list-style-type: none"> 1. Macules and papules: flat top, scaling, non-pruritic, sharply defined, circular/annular rash (DDx: pityriasis rosea, tinea corporis, drug eruptions, lichen planus) 2. Condyloma lata: wart-like moist papules around genital/perianal region 3. Mucous patches: macerated patches mainly found in oral mucosa 	<ul style="list-style-type: none"> • Extremely rare • 3-7 years after secondary • Main skin lesion: 'Gumma' – a granulomatous non-tender nodule
Investigations	<ul style="list-style-type: none"> • CANNOT be based on clinical presentation alone • VDRL negative – repeat weekly for 1 month • Fluorescent treponemal antibody-syphilis (FTA-ABS) test has greater sensitivity and may detect disease earlier in course • Darkfield examination – spirochete in chancre fluid or lymph node aspirate 	<ul style="list-style-type: none"> • VDRL positive • FTA-ABS +ve; –ve after 1 year following appearance of chancre • Darkfield +ve in all secondary 	<ul style="list-style-type: none"> • As in primary syphilis, VDRL can be falsely negative
Management	<ul style="list-style-type: none"> • Penicillin G, 2.4 million units IM, single dose 	<ul style="list-style-type: none"> • As for primary syphilis 	<ul style="list-style-type: none"> • Treatment: penicillin G, 2.4 million units IM weekly

GONOCOCCEMIA

Clinical Presentation

- disseminated gonococcal infection
- hemorrhagic, tender, pustules on a purpuric/petechial background
- sites: distal aspects of extremities
- associated with fever, arthritis, urethritis, proctitis, pharyngitis and tenosynovitis
- neonatal conjunctivitis if infected via birth canal

Etiology

- *Neisseria gonorrhoeae*

Management

- notify Public Health authorities
- screen for other sexually transmitted infections (STIs)
- cefixime 400 mg PO (drug of choice) or ceftriaxone 125 mg IM

Natural History of Untreated Syphilis

- Inoculation
- Primary syphilis (10-90 d after infection)
- Secondary syphilis (simultaneous to primary syphilis or up to 6 mo after healing of primary lesion)
- Latent syphilis
- Tertiary syphilis (2-20 y)

Latent Syphilis

The period between healing of clinical lesions and appearance of late manifestations. 70% of untreated patients will remain in this stage for the rest of their lives and are immune to new primary infection.

Pre-Malignant Skin Conditions

- **actinic keratosis:** 1-10% become squamous cell carcinoma (SCC)
- **dysplastic nevi:** risk of malignant melanoma (see Table 5)

Leukoplakia

Clinical Presentation

- a morphologic term describing homogenous or speckled white plaques with sharply demarcated borders
- sites: oropharynx, most often floor of the mouth, soft palate, and ventral/lateral surfaces of the tongue

Pathophysiology

- precancerous or premalignant condition
- oral form is strongly associated with tobacco use and alcohol consumption

Epidemiology

- 1-5% prevalence in adult population after 30 years of age; peak at age 50
- M>F, fair-skinned
- most common oral mucosal premalignant lesion

Differential Diagnosis

- lichen planus, oral hairy leukoplakia

Investigations

- biopsy is mandatory because it is premalignant

Management

- low risk sites on buccal/labial mucosal or hard palate: eliminate carcinogenic habits, follow-up
- moderate/dysplastic lesions: excision, cryotherapy

Malignant Skin Tumours

Basal Cell Carcinoma (BCC)

Subtypes

- noduloulcerative (typical)
 - skin-coloured papule/nodule with rolled, translucent ("pearly") telangiectatic border and depressed/eroded/ulcerated centre
- pigmented variant
 - flecks of pigment in translucent lesion with surface telangiectasia
 - may mimic malignant melanoma
- superficial variant
 - flat, tan to red-brown plaque, often with scaly, pearly border and fine telangiectasia at margin
- sclerosing variant
 - flesh/yellowish-coloured, shiny papule/plaque with indistinct borders

Pathophysiology

- malignant proliferation of basal cells of the epidermis
 - low grade cutaneous malignancy, locally aggressive (primarily tangential growth), rarely metastatic
 - usually due to UVB light, therefore >80% on face
 - may also be caused by scar formation, radiation, trauma, arsenic exposure, or genetic predisposition (Gorlin syndrome)

Epidemiology

- most common malignancy in humans
- 75% of all malignant skin tumours >40 years, increased prevalence in the elderly
- M>F, skin phototypes I and II, chronic cumulative sun exposure

Differential Diagnosis

- benign: sebaceous hyperplasia, intradermal melanocytic nevus, dermatofibroma
- malignant: nodular malignant melanoma, SCC

Work-up of Nonmelanoma Skin Cancers (NMSC)

- **History:** duration, growth rate, family/personal hx of skin cancer, prior therapy to the particular lesion.
- **Physical:** location, size, whether circumscribed, tethering to deep structures, full skin exam, lymph node exam
- **Biopsy:** if shallow lesion do shave biopsy; otherwise punch biopsy.

Margins

- **Smaller lesions:** electrodesiccation and curettage with 2-3 mm margin of normal skin.
- **Deep infiltrative lesions:** surgical excision with 3-5 mm margins beyond visible and palpable tumour border; may require skin graft or flap.

Management

- imiquimod 5% cream (Aldara®) or cryotherapy is indicated for superficial BCCs on the trunk
- shave excision + electrodesiccation and curettage for all other types of BCCs
- microscopically controlled, minimally invasive, stepwise excision (Mohs surgery) or radiotherapy for lesions on the face or in areas that are difficult to reconstruct
- life-long follow-up
- 95% cure rate if lesion <2 cm in diameter

Cutaneous T-Cell Lymphoma

Clinical Presentation

- **Mycosis fungoides** (limited superficial type)
 - characterized by: erythematous patches/plaques/nodules/tumours, which may be pruritic and poikilodermic (atrophy, telangiectasia, hyperpigmentation)
 - common sites include: trunk, buttocks, proximal limbs
 - mildly symptomatic, usually excellent prognosis for early disease
- **Sezary syndrome** (widespread systemic type)
 - rare variant characterized by: universal erythroderma ("redman syndrome"), lymphadenopathy, WBC >20 x 10⁹/L with Sezary cells
 - associated with intense pruritus, alopecia, palmoplantar hyperkeratosis, and systemic symptoms (fatigue, fever)
 - often fatal

Pathophysiology

- clonal proliferation of skin-homing CD4 T cells

Epidemiology

- >50 years old, M:F 2:1

Differential Diagnosis

- tinea corporis, nummular dermatitis, psoriasis, discoid lupus erythematosus, Bowen's disease

Investigations

- skin biopsy (histology, "lymphocyte antigen cell" markers, TcR gene arrangement)
- blood smear looking for Sezary cells or flow cytometry (e.g. CD4:CD8 >10 is Sezary)
- imaging (for systemic involvement)

Management

- **Mycosis fungoides**
 - treatment is dependent on stage of disease
 - topical steroids and/or PUVA, narrow band (311-313 nm), UVB (NB-UVB)
- **Sezary syndrome**
 - oral retinoids and interferon
 - extra-corporeal photophoresis
 - may need radiotherapy for total skin electron beam radiation
 - may maintain on UV therapy

Malignant Melanoma (MM)

Clinical Presentation

- malignant characteristics of a mole: see mnemonic "ABCDE"
- sites: skin, mucous membranes, eyes, CNS

Subtypes of Malignant Melanoma

- **lentigo maligna**
 - malignant melanoma *in situ* (normal and malignant melanocytes confined to the epidermis)
 - 2-6 cm, tan/brown/black uniformly flat macule or patch with irregular borders
 - lesion grows radially and produces complex colours
 - sites: face, sun exposed areas
 - 1/3 evolve into lentigo maligna melanoma
- **lentigo maligna melanoma** (15% of all melanomas)
 - malignant melanocytes invading into the dermis
 - associated with pre-existing solar lentigo, not pre-existing nevi
 - flat, brown, stain-like, gradually enlarging with loss of skin surface markings
 - with time, colour changes from uniform brown to dark brown with black and blue
 - found on all skin surfaces, especially those often exposed to sun

**Does this Patient have a Mole or Melanoma?**

JAMA 1998; 279(9): 696-701

ABCDE checklist

Asymmetry
Border (irregular)
Colour (varied)
Diameter (increasing or >6 mm)
Enlargement, elevation, evolution

Sensitivity 92% (CI 82-96%)
Specificity 100% (CI 54-100%)

- **superficial spreading melanoma** (60-70% of all melanomas)
 - atypical melanocytes initially spread laterally in epidermis then invade the dermis
 - irregular, indurated, enlarging plaques with red/white/blue discolouration, focal papules or nodules
 - ulcerate and bleed with growth
- **nodular melanoma** (30% of all melanomas)
 - atypical melanocytes that initially grow vertically with little lateral spread
 - uniformly ulcerated, blue-black, and sharply delineated plaque or nodule
 - rapidly fatal
- **acrolentiginous melanoma** (5% of all melanomas)
 - ill-defined dark brown, blue-black macule
 - palmar, plantar, subungual skin
 - melanomas on mucous membranes have poor prognosis

Pathophysiology

- malignant neoplasm of pigment forming cells (melanocytes and nevus cells)

Epidemiology

- incidence 1:100
- risk factors: numerous moles, fair skin, red hair, positive personal/family history, large congenital nevi, familial dysplastic nevus syndrome
- most common sites: back (males), calves (females)
- worse prognosis if: male, on scalp, hands, feet, late lesion, no pre-existing nevus present

Differential Diagnosis

- benign: nevi, solar lentigo, seborrheic keratosis
- malignant: pigmented BCC

Management

- excisional biopsy preferable, otherwise incisional biopsy
- remove full depth of dermis and extend beyond edges of lesion only after histologic diagnosis
- beware of lesions that regress – tumour is usually deeper than anticipated
- lymph node dissection shows survival advantage if nodes uninvolved
- chemotherapy (cis-platinum, BCG), high dose interferon for stage II (regional) and stage III (distant) disease
- radiotherapy may be used as adjunctive treatment

Table 23. American Joint Committee on Cancer Staging System Based on Breslow's Thickness of Invasion

T1 <1.0 mm	Stage I T1a - T2a	5-year survival 90%
T2 1.01-2.0 mm	Stage II T2b - T4b	5-year survival 70%
T3 2.01-4.0 mm	Stage III any nodes	5-year survival 45%
T4 >4.0 mm	Stage IV any mets	5-year survival 10%

a = no ulceration; b = ulceration

Risk Factors for Melanoma

no SPF is a SIN

Sun exposure

Pigment traits (blue eyes, fair/red hair, pale complexion)

Freckling

Skin reaction to sunlight (increased incidence of sunburn)

Immunosuppressive states (e.g. renal transplantation)

Nevi (dysplastic nevi; increased number of benign melanocytic nevi)

Node Dissection for Lesions > 10 mm

- Assess sentinel nodes
- If macroscopically or microscopically positive, a lymph node dissection should be performed prior to wide excision of the primary melanoma to ensure accurate lymphatic mapping.

Squamous Cell Carcinoma (SCC)

Clinical Presentation

- indurated erythematous nodule/plaque with surface scale/crust, and eventual ulceration
- more rapid enlargement than BCC
- sites: face, ears, scalp, forearms, dorsum of hands

Pathophysiology

- malignant neoplasm of keratinocytes (primarily vertical growth)
- predisposing factors include: UV radiation, PUVA, ionizing radiation therapy/exposure, chemical carcinogens (such as arsenic, tar and nitrogen mustards), HPV 16, 18, immunosuppression

Epidemiology

- second most common type
- primarily on sun-exposed skin in the elderly, M>F, skin phototypes I and II, chronic sun exposure
- in organ transplant recipients SCC is most common cutaneous malignancy, with increased mortality

Differential Diagnosis

- benign: nummular eczema, psoriasis, irritated seborrheic keratosis
- malignant: keratoacanthoma, Bowen's disease, BCC

Management

- surgical excision with primary closure, skin flaps or grafting
- lifelong follow-up (more aggressive treatment than BCC)

Prognosis

- good prognostic factors: immediate treatment, negative margins, and small size of lesion
- SCCs that arise from actinic keratosis metastasize less frequently (~1%) than other SCCs (e.g. arising de novo in old burns) (2-5% of cases)
- overall control is 75% over 5 years, 5-10% metastasize

BOWEN'S DISEASE (SQUAMOUS CELL CARCINOMA IN SITU)**Clinical Presentation**

- erythematous plaque with a sharply demarcated red and scaly border
- often 1-3 cm in diameter and found on the skin and mucous membranes
- evolves to SCC in 10-20% of cutaneous lesions and >20% of mucosal lesions

Management

- same as for BCC
- biopsy required for diagnosis
- topical 5-fluorouracil (Efudex®) or imiquimod (Aldara®) used if extensive and as a tool to identify margins of poorly defined tumours
- shave excision with electrodesiccation and curettage

Alopecia (Hair Loss)

Hair Growth

- hair grows in a cyclic pattern that is defined in 3 stages
 1. growth stage = anagen phase
 2. resting stage = telogen phase
 3. degenerative stage = catagen phase
- total duration of the growth stage reflects the type and location of hair: eyebrow, eyelash, and axillary hairs have a short growth stage in relation to the resting stage
- growth of the hair follicles is also based on the hormonal response to testosterone and dihydrotestosterone (DHT): this response is genetically controlled

Non-Scarring (Non-Cicatricial) Alopecia

PHYSIOLOGICAL**Clinical Presentation**

- male-pattern alopecia (androgenic alopecia)
- fronto-temporal areas progressing to vertex, entire scalp may be bald

Pathophysiology

- action of testosterone on hair follicles

Epidemiology

- early 20's-30's (female androgenic alopecia is diffuse and occurs in 40's and 50's)

Management

- minoxidil (Rogaine®) lotion to reduce rate of loss/partial restoration
- spironolactone in women (anti-androgenic effects), cyproterone acetate (Diane-35®)
- finasteride (Propecia®) (5- α -reductase inhibitor) 1 mg/d in men
- hair transplant

PHYSICAL

- trichotillomania: impulse-control disorder characterized by compulsive hair pulling with irregular patches of hair loss, and with remaining hairs broken at varying lengths
- traumatic (e.g. tight "corn-row" braiding of hair)

**Hair Loss****TOP HAT**

Telogen effluvium, tinea capitis

Out of Fe, Zn

Physical – trichotillomania, "corn-row" braiding

Hormonal – hypothyroidism, androgenic

Autoimmune – SLE, alopecia areata

Toxins – heavy metals, anticoagulants, chemotherapy, Vit A, SSRIs

TELOGEN EFFLUVIUM**Clinical Presentation**

- uniform decrease in hair density secondary to an increased number of hairs in resting stage (telogen stage)

Pathophysiology

- precipitated by: malnutrition, Fe deficiency, thyroid dysfunction, post-partum/miscarriage, scalp diseases (seborrheic dermatitis, allergic contact dermatitis), medications (e.g. OCP), physical/mental stress, Fe deficiency
- hair loss typically occurs 2-4 month after exposure to precipitant
- regrowth occurs within a few months but may not be complete

ANAGEN EFFLUVIUM**Clinical Presentation**

- hair loss due to insult to hair follicle impairing its mitotic activity (growth stage)

Pathophysiology

- precipitated by chemotherapeutic agents (most common), other meds (bismuth, levodopa, colchicine, cyclosporine), exposure to chemicals (thallium, boron, arsenic)
- dose-dependent effect
- hair loss 7-14 days after single pulse of chemotherapy; most clinically apparent after 1-2 months
- reversible effect; follicles resume normal mitotic activity few weeks after agent stopped

ALOPECIA AREATA**Clinical Presentation**

- autoimmune disorder characterized by patches of complete hair loss localized to scalp, eyebrows, beard, eyelashes
- alopecia totalis – loss of all scalp hair and eyebrows
- alopecia universalis – loss of all body hair
- associated with dystrophic nail changes – fine stippling
- “exclamation mark” pattern (hairs fractured and have tapered shafts, i.e. looks like “!”)
- may be associated with pernicious anemia, vitiligo, thyroid disease, Addison’s disease
- spontaneous regrowth may occur within months of first attack (worse prognosis if young at age of onset and extensive loss)
- frequent recurrence often precipitated by emotional distress

Management

- generally unsatisfactory
- intralesional triamcinolone acetonide (corticosteroids) can be used for isolated patches
- UV or PUVA therapy
- immunomodulatory (diphencyprone)

Scarring (Cicatricial) Alopecia**Clinical Presentation**

- irreversible loss of hair follicles with fibrosis

Etiology

- physical: radiation, burns
- infections: fungal, bacterial, TB, leprosy, viral (herpes zoster)
- inflammatory
 - lichen planus (lichen planopilaris)
 - discoid lupus erythematosus (DLE) (note that SLE can cause an alopecia unrelated to discoid lupus lesions which are non-scarring)
 - morphea: “coup de sabre” with involvement of centre of scalp

Investigations

- biopsy from active border

Management

- infections: treat underlying infection
- inflammatory: DLE treated topical/intralesional steroid or antimalarial

Non-scarring alopecia: intact hair follicles on exam → biopsy not required.

Scarring alopecia: absent hair follicles on exam → biopsy required.

**DDx of Non-scarring (non-cicatricial) Alopecia**

Alopecia

- Autoimmune
 - Alopecia areata
- Endocrine
 - Hypothyroidism
 - Androgens
- Micronutrient deficiencies
 - Iron
 - Zinc
- Toxins
 - Heavy metals
 - Anticoagulants
 - Chemotherapy
 - Vitamin A
- Trauma to the hair follicle
 - Trichotillomania
 - ‘Corn-row’ braiding
- Other
 - Severe illness
 - Childbirth

**DDx of Scarring (cicatricial) Alopecia**

Developmental/Hereditary Disorders

- Aplasia cutis congenita
- Epidermal nevi
- Romberg’s syndrome
- Generalized follicular hamartoma

Primary causes

- Group 1: Lymphocytic
 - Lupus erythematosus
 - Lichen planopilaris
 - Classic Pseudopelade
- Group 2: Neutrophilic
 - Folliculitis decalvans
- Group 3: Mixed
 - Acne keloidalis nuchae

Secondary causes

- Infectious agents
 - Bacterial (i.e. post-cellulitis)
 - Fungal (i.e. tinea capitis)
- Neoplasms (i.e. BCC, SCC, Lymphomas, and metastatic tumours)
- Physical agents
 - Mechanical trauma
 - Burns
 - Radiotherapy
 - Caustic chemicals

Nails and Disorders of the Nail Apparatus

Table 24. Nail Changes in Systemic and Dermatological Conditions

Nail Abnormality	Definition/Etiology	Associated Disease
NAIL PLATE CHANGES		
Clubbing	Proximal nail plate has greater than 180 degree angle to nail fold, watch-glass nails, bulbous digits	Cyanotic heart disease, bacterial endocarditis, pulmonary disorders, GI disorders, etc.
Koilonychia	Spoon shaped nails	Iron deficiency, malnutrition, diabetes
Onycholysis	Separation of nail plate from nail bed	Psoriasis, dermatophytes, thyroid disease
Onychogryphosis	Hypertrophy of the nail plate and subungal hyperkeratosis	Poor circulation, chronic inflammation, tinea
Onychohemia	Subungual hematoma	Trauma to nail bed
Onychomycosis	Fungal infection of nail (e.g. dermatophyte, yeast, mould)	HIV, diabetes, peripheral arterial disease
Onychocryptosis (Ingrown toenail)	Often hallux with congenital malalignment, painful inflammation, granulation tissue	Tight fitting shoes, excessive nail clipping
SURFACE CHANGES		
Wedge shaped	Distal margin has v-shaped indentation	Darier's disease (follicular dyskeratosis)
Pterygium inversus unguis	Distal nail plate does not separate from underlying nail bed	Scleroderma
Pitting	Punctate depressions that migrate distally with growth	Psoriasis, alopecia areata, eczema
Transverse ridging	Transverse depressions often more in central portion of nail plate	Serious acute illness slows nail growth (Beau's lines), eczema, chronic paronychia, trauma
Transverse white lines	Bands of white discolouration	Poisons, hypoalbuminemia (Muherke's lines)
COLOUR CHANGES		
Yellow		Tinea, jaundice, tetracycline, pityriasis rubra pilaris, yellow nail syndrome
Green		Pseudomonas
Black		Melanoma, hematoma
Brown		Nicotine use, psoriasis, poisons
Splinter hemorrhages	Extravasation of blood from longitudinal vessels of nail bed Blood attaches to overlying nail plate and moves distally as it grows	Trauma, bacterial endocarditis, blood dyscrasias, psoriasis
Oil spots	Brown-yellow discolouration	Psoriasis
NAIL FOLD CHANGES		
Herpetic whitlow	HSV infection of distal phalanx	Genital herpes infection
Paronychia	Local inflammation of the nail fold around the nail bed	Acute: painful infection Chronic: constant wetting (e.g. dishwashing, thumbsucking)
Nail fold telangiectasias	Cuticular hemorrhages, roughness, capillary changes	Scleroderma, SLE

Skin Manifestations of Systemic Disease

Table 25. Skin Manifestations of Internal Conditions

Disease	Related Dermatoses
AUTOIMMUNE DISORDERS	
Behçet's disease	Painful aphthous ulcers in oral cavity ± genital mucous membranes, erythema nodosum
Buerger's disease	Superficial migratory thrombophlebitis, pallor, cyanosis, gangrene, ulcerations
Dermatomyositis	Periorbital and perioral violaceous erythema, heliotrope with edema, Gottron's papules (violaceous flat-topped papules with atrophy), periungual erythema, telangiectasia, calcinosis cutis
Polyarteritis nodosa	Polyarteritic nodules, stellate purpura, erythema, gangrene, splinter hemorrhages, livedo reticularis
Rheumatic fever	Petechiae, urticaria, erythema nodosum, rheumatic nodules
Scleroderma	Raynaud's, nonpitting edema, waxy/shiny/tense atrophic skin (morphea), ulcers, cutaneous calcification, periungual telangiectasia, acrosclerosis
Systemic lupus erythematosus	Malar erythema, discoid rash (erythematous papules or plaques with keratotic scale, follicular plugging, atrophic scarring on face, hands, and arms), hemorrhagic bullae, palpable purpura, urticarial purpura, patchy/diffuse alopecia, mucosal ulcers, photosensitivity
Ulcerative colitis (UC)	Pyoderma gangrenosum, erythema nodosum
ENDOCRINE DISORDERS	
Addison's disease	Generalized hyperpigmentation or limited to skin folds, buccal mucosa and scars
Cushing's syndrome	Moon facies, purple striae, acne, hyperpigmentation, hirsutism, atrophic skin with telangiectasia
Diabetes mellitus	Infections (boils, carbuncles, candidiasis, <i>S. aureus</i> , dermatophytoses, tinea pedis and cruris, infectious eczematoid dermatitis), pruritus, eruptive xanthomas, necrobiosis lipidica diabetorum, granuloma annulare, diabetic foot, diabetic bullae, acanthosis nigricans, calciphylaxis
Hyperthyroidism	Moist, warm skin, seborrhea, acne, nail atrophy, hyperpigmentation, toxic alopecia, pretibial myxedema, acropachy, onycholysis
Hypothyroidism	Cool, dry, scaly, thickened, hyperpigmented skin; toxic alopecia with dry, coarse hair, brittle nails, myxedema, loss of lateral 1/3 eyebrows
HIV-RELATED	
Infections	Viral (HSV, HZV, HPV, cytomegalovirus, molluscum contagiosum, oral hairy leukoplakia), bacterial (impetigo, acneiform folliculitis, dental caries, cellulitis, bacillary epithelioid angiomatosis, syphilis), other (candidiasis)
Inflammatory dermatoses	Seborrhea, psoriasis, pityriasis rosea, vasculitis
Malignancies	Kaposi's sarcoma, lymphoma, BCC, SCC, malignant melanoma
MALIGNANCY	
Adenocarcinoma	
Gastrointestinal (GI)	Peutz-Jeghers: pigmented macules on lips/oral mucosa
Cervix/anus/rectum	Paget's Disease: eroding scaling plaques of perineum
Carcinoma	
Breast	Paget's Disease: eczematous and crusting lesions of breast
GI	Palmoplantar keratoderma: thickened skin of palms/soles
Thyroid	Sipple's Syndrome: multiple mucosal neuromas
Breast/GU/lung/ovary	Dermatomyositis: heliotrope erythema of eyelids and purplish plaques over knuckles
Lymphoma/Leukemia	
Hodgkin's	Ataxia Telangiectasia: telangiectasia on pinna, bulbar conjunctiva
Acute Leukemia	Ichthyosis: generalized scaling especially on extremities
	Bloom's syndrome: butterfly erythema on face, associated with short stature
Multiple Myeloma	Amyloidosis: large, smooth tongue with waxy papules on eyelids, nasolabial folds and lips, as well as facial petechiae
OTHERS	
Liver disease	Pruritus, hyperpigmentation, spider nevi, palmar erythema, white nails (Terry's nails), porphyria cutanea tarda, xanthomas, hair loss
Renal disease	Pruritus, pigmentation, half and half nails
Pruritic urticaria papules and plaques of pregnancy	Erythematous papules or urticarial plaques in distribution of striae distensae: buttocks, thighs, upper inner arms and lower backs
Cryoglobulinemia	Palpable purpura in cold-exposed areas, Raynaud's, cold urticaria, acral hemorrhagic necrosis, bleeding disorders, associated with hepatitis C infection

Raynaud's Phenomenon DDx

COLD HAND

Cryoglobulins/Cryofibrinogens
Obstruction/Occupational
Lupus erythematosus, other connective tissue disease
Diabetes mellitus/Drugs
Hematologic problems (polycythemia, leukemia, etc)
Arterial problems (atherosclerosis)
Neurologic problems (vascular tone)
Disease of unknown origin (idiopathic)

Acanthosis Nigricans

An asymptomatic dark thickened velvety hyperpigmentation of flexural skin most commonly around the neck. Associated with diabetes, obesity and other endocrine disorders and malignancy. It is a cutaneous marker of tissue insulin resistance.

Pediatric Exanthems

Itchy Eruptions in Childhood

UC-SCAB

Urticaria
Contact dermatitis
Scabies
Chicken pox
Atopic dermatitis
Bites

Definitions

- exanthem: an eruption on the skin occurring as a symptom of a systemic disease typically with a fever
- enanthem: an eruption on a mucous membrane occurring in the context of an exanthem

Table 26. Common Pediatric Exanthems

Exanthem	Etiology	Clinical Description	Important Complications	Management
Chicken Pox	Human herpes virus (HHV) 3 Incubation 10-21d, Communicable 1-2d Pre-rash to 5d post-rash	Diffuse vesicular pustular eruption beginning on thorax spreading to extremities New lesions every 2-3d Enanthems	Necrotizing fasciitis, encephalitis, cerebellar ataxia, disseminated intravascular coagulation (DIC), hepatitis	Supportive therapy, Acyclovir if severe, Varicella Zoster immunoglobulin (within 96 hrs of contact), Varicella vaccine
Enteroviral	Enteroviruses Most common exanthem in summer and fall	Polymorphous rash (macules, papules, vesicles, petechiae, urticaria)	None	Supportive care for majority Serious cases (immunosuppressed) can be treated with pleconaril
Erythema Infectiosum	Parvovirus B19 Incubation 4-14d Peaks in winter and spring	Slapped cheeks (red, flushed cheeks) then 1-4 days later lacy/reticular maculo-papular rash of trunk/extremities	STAR complex (Sore Throat, Arthritis, Rash) Fetal infection (anemia, fetal hydrops or death) Aplastic crisis in sickle cell patients	No treatment: children often feel well NSAIDs for symptomatic arthropathy
Gianotti-Crosti Syndrome	Epstein-Barr virus most common, hepatitis B, coxsackie, parvovirus Spring and early summer	Symmetric papular eruption of face, buttocks, and extremities	None	Supportive treatment
Hand, Foot and Mouth Disease	Coxsackie A and B viruses Highly contagious virus	Vesicular eruption of palms and soles with an erosive stomatitis	Pulmonary, neurological death	Supportive treatment
Kawasaki Disease	No proven viral etiology, but infectious etiology suggested Superantigen toxin-mediated bacterial process proposed Late winter to early spring	Fever >5 days and 4/5: unilateral lymphadenopathy; puffy/red palms and soles; red, cracked lips/strawberry tongue; skin rash; non-purulent bilateral conjunctivitis	Most common cause of vasculitis and acquired heart disease in children CNS, GI tract, kidney, eyes	Aspirin, intravenous immunoglobulin, baseline echo and repeat in 6 weeks
Measles	Paramyxovirus Incubation 10-14d Communicable 4d before and after rash	Erythematous macular eruption beginning on head and spreading downwards, desquamates, no palm or sole involvement Enanthem: Koplik spots (grey/white papules on buccal mucosa)	Otitis media, pneumonia, encephalitis, SJS, glomerular nephritis, myocarditis/pericarditis	Vitamin A, immunoglobulin, measles/mumps/rubella (MMR) vaccine
Roseola	HHV 6, HHV 7 Incubation 9-10d	Pink macules and papules on trunk, neck, proximal extremities, and occasionally face Eruption after high fever ends	Neurological involvement Viral reactivation in immunosuppressed patients	Supportive treatment Antipyretics during the febrile period
Rubella	RNA virus of the Togaviridae family Incubation 16-18d	1-5 days following mild prodrome (fever, headache, respiratory symptoms), a pink maculo-papular rash erupts on face spreading in a cephalocaudal direction Occipital and retroauricular nodes	STAR complex Congenital rubella (cataract, glaucoma, thrombocytopenia, hepatitis, deafness, congenital heart disease)	Supportive treatment MMR vaccine Serologic testing in rubella-exposed pregnant women
Scarlet Fever	Group A beta-hemolytic streptococci toxin types A, B, and C Late fall, winter, and early spring	Generalized rash, red papules, "sand-paper" texture, desquamation, flexural accentuation, enanthem (strawberry tongue, petechiae on palate) Pastia's lines – linear petechial streaks in axillary, inguinal, and antecubital areas	Mastoiditis, otitis, sinusitis, pneumonia, meningitis, myocarditis, arthritis, hepatitis, rheumatic fever, and glomerulonephritis	10-14 day course of penicillin

Miscellaneous Lesions

Angioedema and Urticaria

Angioedema

- deeper swelling of the skin involving subcutaneous tissues; often involves the eyes, lips, and tongue
- may or may not accompany urticaria
- hereditary or acquired forms
- hereditary angioedema (does not occur with urticaria)
 - onset in childhood; 80% have positive family history
 - recurrent attacks; 25% die from laryngeal edema
 - triggers: minor trauma, emotional upset, temperature changes
- treatment
 - prophylaxis with danazol or stanozolol
 - epinephrine pen to temporize until patient reaches hospital in acute attack

Urticaria

- also known as “Hives”; see Table 27 for classification
- transient, red, pruritic well-demarcated wheals
- each individual lesion lasts less than 24 hours
- second most common type of drug reaction
- results from release of histamine from mast cells in dermis
- can also result after physical contact with allergen

Table 27. Classification of Urticaria

Type	Approach to Diagnosis
Acute Urticaria >2/3 of cases Attacks last <6 weeks Individual lesions last <24 hrs	Drugs – especially aspirin, NSAIDs Foods – nuts, shellfish, eggs, fruit Idiopathic Infection Insect stings Percutaneous absorption – cosmetics, work exposures Stress Systemic diseases – systemic lupus erythematosus (SLE), endocrinopathy, neoplasm
Chronic Urticaria <1/3 of cases Attacks last >6 weeks Individual lesion lasts <24 hrs	IgE-dependent: trigger associated Idiopathic (90% of chronic urticaria patients) Aeroallergens Drugs (antibiotics, hormones, local anesthetics) Foods and additives Insect stings (bees, wasps, hornets) Parasitic infections Physical contact (animal saliva, plant resins, latex, metals, lotions, soap) Direct mast cell release Opiates, muscle relaxants, radio-contrast agents Complement-mediated Serum sickness, transfusion reactions Infections, viral/bacterial (>80% of urticaria in pediatric patients) Urticarial vasculitis Arachidonic acid metabolism ASA, NSAIDs Physical Dermatographism (friction, rubbing skin), cold (ice cube, cold water), cholinergic (hot shower, exercise), solar, pressure (shoulder strap, buttocks), aquagenic (exposure to water), adrenergic (stress), heat Other Mastocytosis, urticaria pigmentosa
Vasculitic Urticaria Individual lesions last >24 hrs Painful, non-pruritic Requires biopsy	Idiopathic Infections Hepatitis Autoimmune diseases SLE Drug hypersensitivity cimetidine and diltiazem

Wheal

- Typically erythematous flat-topped, palpable lesions varying in size with circumscribed dermal edema
- Individual lesion lasts <24 hrs
- Associated with mast cell release of histamine
- May be pruritic

DDx for Urticaria

DAM HIVES

- Drugs and foods
- Allergic
- Malignancy
- Hereditary
- Infection
- Vasculitis
- Emotions
- Stings

Approach to Urticaria

1. Thorough Hx and P/E
2. **Acute:** if individual lesions last <24 hours, but attacks last <6 weeks; no immediate investigations needed; consider referral for allergy testing
3. **Chronic:** if individual lesions last <24 hours but attacks last >6 weeks; further investigations required: CBC + diff, urinalysis, ESR, LFTs to help identify underlying cause
4. **Vasculitic:** if individual lesions last >24 hours; biopsy of lesion and referral to dermatology

Mastocytosis (Urticaria Pigmentosa)

Rare disease due to excessive infiltration of the skin by mast cells. It manifests as many reddish-brown elevated plaques and macules. Applying pressure to a lesion produces a wheal surrounded by intense erythema (Darier's sign), due to mast cell degranulation. This occurs within minutes.

Erythema Nodosum

Clinical Presentation

- acute or chronic inflammation of subcutaneous fat (panniculitis)
- round, red, tender, poorly demarcated nodules
- sites: asymmetrically arranged on lower legs, knees, arms
- associated with arthralgia, fever, malaise

Etiology

- 40% are idiopathic
- drugs: sulfonamides, oral contraceptives (also pregnancy), analgesics, trans retinoic acid
- infections: GAS, primary tuberculosis (TB), histoplasmosis, *Yersinia*
- inflammation: sarcoidosis, Crohn's > ulcerative colitis
- malignancy: acute leukemia, Hodgkin's lymphoma

Epidemiology

- 15-30 years old, F:M = 3:1
- lesions last for days and spontaneously resolve in 6 weeks

Investigations

- chest x-ray (to rule out chest infection and sarcoidosis)
- throat culture, antistreptolysin (ASO) titre, purified protein derivative (PPD) skin test

Management

- symptomatic: bed rest, compressive bandages, wet dressings
- NSAIDs
- treat underlying cause

DDx of Erythema Nodosum

NODOSUM

No cause (idiopathic) in 40%

Drugs (sulfonamides, OCP, etc.)

Other infections (GAS +)

Sarcoidosis

Ulcerative colitis and Crohn's

Malignancy (leukemia, Hodgkin's lymphoma)

Pruritus

Clinical Presentation

- a sensation provoking a desire to scratch
- pruritus can present with or without skin lesions
- lesions may arise from the underlying disease, or from excoriation causing crusts, lichenified plaques, or wheals

Etiology

- dermatologic – generalized
 - asteatotic dermatitis ("winter itch")
 - pruritus of senescent skin (may not have dry skin, any time of year)
 - infestations: scabies, lice
 - drug eruptions: ASA, antidepressants, opiates
 - psychogenic states
- dermatologic – local
 - atopic and contact dermatitis, lichen planus, urticaria, insect bites, dermatitis herpetiformis
 - infection: varicella, candidiasis
 - lichen simplex chronicus
 - prurigo nodularis
- systemic disease – usually generalized
 - hepatic: obstructive biliary disease, cholestatic liver disease of pregnancy
 - renal: chronic renal failure, uremia secondary to hemodialysis
 - hematologic: Hodgkin's lymphoma, multiple myeloma, leukemia, polycythemia vera, hemochromatosis, Fe deficiency anemia, cutaneous T-cell lymphoma
 - neoplastic: lung, breast, gastric (internal solid tumours)
 - endocrine: carcinoid, DM, hypothyroid/thyrotoxicosis
 - infectious: HIV, trichinosis, echinococcosis, hepatitis C
 - psychiatric: depression, psychosis
 - neurologic: post-herpetic neuralgia, multiple sclerosis

Investigations

- detailed history
- complete physical, including rectal and pelvic examination
- bloodwork: CBC, ESR, Cr/BUN, LFT, TSH, fasting blood sugar, stool culture and serology for parasites

DDx of Pruritus

SCRATCHED

Scabies

Cholestasis

Renal

Autoimmune

Tumours

Crazies (psychiatric)

Hematology (polycythemia, lymphoma)

Endocrine (thyroid, parathyroid, ↓ Fe)

Drugs, dry skin

Management

- treat underlying cause
- cool water compresses to relieve pruritus
- bath oil and emollient ointment (especially if xerosis is present)
- topical corticosteroid and antipruritics (e.g. menthol, camphor, phenol, mirtazapine, capsaicin)
- systemic antihistamines: H1 blockers are most effective, most useful for urticaria
- phototherapy with UVB or PUVA

Wounds and Ulcers**Table 28. Different Types of Ulcers and Treatment**

Ulcer Type	Clinical Presentation	Management
Arterial	Wound at tips of toes, cold feet with claudication, gangrene, distal hyperemia, decreased pedal pulses	Doppler study If ankle:brachial ratio <0.4, consider amputation If gangrenous, paint with betadine Otherwise, dressings to promote moist interactive wound healing
Venous	Wound at malleolus, stasis change, edema, previous venous injury	Local wound dressing: moist interactive healing Compression: preferably four layers After wound heals, support stockings for life
Neurotropic and Diabetic	Wound at pressure point or secondary to unknown trauma, common at base of 1st metatarsal phalangeal (MTP)	Pressure downloading by using proper shoes/seats Promote moist interactive wound healing Appropriate broad-spectrum antibiotic coverage
Vasculitic	Livedo reticularis, petechiae, extreme tenderness, delayed healing	Biopsy to determine vasculitis Serum screening for vasculitis Treat vasculitis Local moist interactive wound healing

**Uncommon Causes of Ulcers****CHIP IN**

Cancer, chromosomal
Hemoglobinopathy
Inflammatory
Pyoderma gangrenosum
Infections
Necrobiosis lipoidica diabetorum

**Key to a Wound that does Not Heal...**

- Relentless debridement of biofilm and antimicrobials
- Biopsy any wound without signs of healing after 3 months to rule out cancer!

Common Medications**Sunscreens and Preventative Therapy****Sunburn**

- erythema 2-6 hours post UV exposure often associated with edema, pain and blistering with subsequent desquamation of the dermis, and hyperpigmentation
- chronic UVB exposure leads to photoaging, immunosuppression, photocarcinogenesis
- prevention: avoid peak UVR (10 am to 4 pm), wear appropriate clothing, wide-brimmed hat, sunglasses, and broad-spectrum sunscreen
- clothing with UV protection expressed as UV protection factor (UPF) is analogous to SPF of sunscreen

Sunscreens

- sun protection factor (SPF): under ideal conditions an SPF of 10 means that a person who normally burns in 20 minutes will burn in 200 minutes following the application of the sunscreen
- topical chemical: absorbs UV light
 - requires application at least 15-60 minutes prior to exposure, should be reapplied every 2 hours (more often if sweating, swimming)
 - UVB absorbers: PABA, salicylates, cinnamates, benzylidene camphor derivatives
 - UVA absorbers: benzophenones, anthranilates, dibenzoylmethanes, benzylidene camphor derivatives
- topical physical: reflects and scatters UV light
 - titanium dioxide, zinc oxide, kaolin, talc, ferric chloride and melanin
 - ♦ all are effective against the UVA and UVB spectrum
 - less risk of sensitization than chemical sunscreens and waterproof, but may cause folliculitis or miliaria
- some sunscreen ingredients may cause contact or photocontact allergic reactions, but are uncommon

Management

- sunburn: if significant blistering present, consider treatment in hospital; otherwise, symptomatic treatment (cool wet compresses, oral anti-inflammatory, topical corticosteroids)
- antioxidants, both oral and topical are being studied for their abilities to protect the skin; topical agents are limited by their ability to penetrate the skin

SPF = burn time with cream/burn time without cream

**UV Radiation****UVA (320-400 nm): Aging**

- Penetrates skin more effectively than UVB or UVC
- Responsible for tanning, burning, wrinkling and premature skin aging
- Penetrates clouds, glass and is reflected off water, snow and cement

UVB (290-320 nm): Burning

- Absorbed by the outer dermis
- Is mainly responsible for burning and premature skin aging
- Primarily responsible for BCC, SCC
- Does not penetrate glass and is substantially absorbed by ozone

UVC (200-290 nm)

- Is filtered by ozone layer

Topical Steroids

Table 29. Potency Ranking of Topical Steroids

Relative Potency	Relative Strength	Generic Names	Trade Names	Usage
Weak	x1	hydrocortisone 1%	Emo Cort®	Intertriginous areas, children, face, thin skin
Moderate	x3	hydrocortisone 2% 17-valerate – 0.2% desonide mometasone furoate	Westcort® Tridesilon® Elocom®	Arm, leg, trunk
Potent	x6	betamethasone – 0.1% 17-valerate – 0.1% amcinonide	Betnovate® Celestoderm – V® Cyclocort®	Body
Very Potent	x9	betamethasone dipropionate – 0.05% fluocinonide – 0.05%	Diprosone® Lidex, Topsyn gel® Lyderm®	Palms and soles
Extremely Potent	x12	clobetasol propionate (most potent) betamethasone dipropionate ointment halobetasol propionate	Dermovate® Diprolene® Ultravate®	Palms and soles

Body Site: Relative Percutaneous Absorption

Forearm	1.0
Plantar foot	0.14
Palm	0.83
Back	1.7
Scalp	3.7
Forehead	6.0
Cheeks	13.0
Scrotum	42.0

Calculation of strength of steroid compared to hydrocortisone on forearm: relative strength of steroid x relative percutaneous absorption

Side Effects of Topical Steroids

- Local: Atrophy
Perioral dermatitis
Steroid acne
Rosacea
Contact dermatitis
Tachyphylaxis (tolerance)
- Systemic: Suppression of HPA axis

Dermatologic Therapies

Table 30. Topical Therapies that are Important in Dermatology

Drug Name	Dosing Schedule	Indications	Comments
Calcipotriol (Dovonex®)	0.005% cream, ointment, scalp solution, apply BID For maintenance therapy apply OD	Psoriasis	Burning, itching, skin irritation, worsening of psoriasis Avoid face, mucous membranes, eyes; wash hands after application Maximum weekly dosage of cream by age: 2-5 years – 25 g/wk 6-10 years – 50 g/wk 11-14 years – 75 g/wk > 14 years – 100 g/wk
Imiquimod (Aldara®)	5% cream applied 3x/wk Apply at bedtime, leave on 6-10 hours, then wash off with mild soap and water Max. duration 16 weeks	Genital warts Cutaneous warts Actinic keratosis Superficial basal cell carcinoma	Avoid natural/artificial sun exposure Local skin and application site reactions Erythema, ulceration, edema, flu-like symptoms Works best for warts on mucosal surfaces May induce inflammation and erosion
Permethrin (Kwellada® P Lotion and Nix® Dermal Cream)	5% cream, applied once overnight to all skin areas from neck down	Scabies (Kwellada-P Lotion, Nix® Dermal Cream) Pediculosis (Kwellada-P Crème Rinse®, Nix Crème Rinse®)	Do not use in children <2 yrs old Hypersensitivity to drug, or known sensitivity to chrysanthemums Local reactions only (resolve rapidly); including burning, pruritis Low toxicity, excellent results Consider 2nd application after 7 days
Pimecrolimus (Elidel®)	1.0% cream BID Use for as long as lesions persist and d/c upon resolution of symptoms	Atopic dermatitis (mild to moderate)	Burning Lacks adverse effects of steroids May be used on all skin surfaces including head, neck, and intertriginous areas Expensive
Tacrolimus topical (Protopic®)	0.03% (children) or 0.1% (adults) ointment BID Continue for duration of disease PLUS x 1 week after clearing	Atopic dermatitis (mild to moderate)	Burning Lacks adverse effects of steroids May be used on all skin surfaces including head, neck, and intertriginous areas Expensive

Vehicles

- Ointment (water in oil): hydrate, greasy
- Cream (oil in water): hydrate, variable
- Lotion (powder in water): drying, cosmesis
- Solutions (water, alcohol, propylene glycol)
- Gel (solution that melts on contact with skin): drying

Table 31. Oral Therapies that are Important in Dermatology

Drug Name	Dosing Schedule	Indications	Comments
Acitretin (Soriatane®)	25-50 mg PO OD; maximum 75 mg/d	Severe psoriasis Other disorders of hyperkeratinization (ichthyosis, Darier's disease)	<u>Monitoring strategies:</u> Monitor lipids, LFTs at baseline and q1-2wk until stable <u>Contraindications:</u> Women of childbearing potential unless strict contraceptive requirements are met <u>Drug interactions:</u> Other systemic retinoids, methotrexate, tetracyclines, certain contraceptives May be combined with PUVA phototherapy (known as re-PUVA)
Antivirals	famcyclovir (Famvir®) 250 mg PO TID x 7-10 days (for 1st episode of genital herpes) 125 mg PO BID x 5 d (for recurrent genital herpes) valacyclovir (Valtrex®) 1000 mg PO BID x 7-10 d (for 1st episode of genital herpes) 500 mg PO BID x 5 d (for recurrent genital herpes)	Chickenpox Herpes zoster Genital Herpes Acute and prophylactic to reduce transmission in infected patients Herpes labialis	<u>Side effects:</u> Headache, nausea, diarrhea, abdominal pain Reduce dose if impaired renal function <u>Side effects:</u> Dizziness, depression, abdominal pain Reduce dose if impaired renal function <u>Drug interactions:</u> cimetidine
Cyclosporin (Neoral®)	2.5-4 mg/kg/d PO div BID Max 4 mg/kg/d After 4 weeks may increase by 0.5 mg/kg/d q2wks Concomitant dose of magnesium may protect the kidneys	Psoriasis May also be effective in: Lichen Planus Dermatitis herpetiformis Erythema multiforme Recalcitrant urticaria Recalcitrant atopic dermatitis	<u>Monitoring strategies:</u> Blood pressure, renal function <u>Contraindications:</u> Abnormal renal function, uncontrolled hypertension, malignancy (except non-melanoma skin cancer), uncontrolled infection, immunodeficiency (excluding autoimmune disease), hypersensitivity to drug Long term effects preclude use of cyclosporin for >2 years; discontinue earlier if possible May consider rotating therapy with other drugs to minimize adverse effects of each drug
Dapsone	50-100-150 mg PO OD tapering to 25-50 mg PO OD to as low as 50 mg 2x/wk	Dermatitis herpetiformis	<u>Monitoring strategies:</u> Obtain G6PD levels before initiating; in the initial two weeks obtain methemoglobin levels and follow the blood counts carefully for the first few months <u>Side effects:</u> Neuropathy Hemolysis (Vitamin C and E supplementation can help prevent this) <u>Drug interactions:</u> Substrate of CYP2C8/9 (minor), 2C19 (minor), 2E1 (minor), 3A4 (major) Often a dramatic response within hours
Isotretinoin (Accutane®)	0.5-1 mg/kg/day given OD, to achieve a total dose of 120 mg/kg (i.e. 16-20 weeks)	Severe nodular and/or inflammatory acne Acne conglobata Recalcitrant acne	<u>Monitoring strategies:</u> Baseline lipid profile and hepatic enzymes before treatment, β-HCG <u>Contraindications:</u> Teratogenic – in females, reliable contraception is necessary Generally regarded as unsafe in lactation <u>Side effects:</u> Night blindness, decreased tolerance to contact lenses, dry mucous membranes May transiently exacerbate acne, dry skin Depression, myalgia <u>Drug interactions:</u> Do not use at the same time as tetracycline or minocycline – both may cause pseudotumour cerebri Discontinue vitamin A supplements Drug may be discontinued at 16-20 weeks when nodule count has dropped by >70%. A second course may be initiated after 2 months pm Refractory cases may require >3 courses
Itraconazole (Sporanox®)	100-400 mg PO OD, depending on infection treated Tinea corporis/cruris: 200 mg PO OD x 7 days Tinea pedis: 200 mg PO BID x 7 days Tinea versicolor: 200 mg PO OD x 7 days Toenails with or without fingernail involvement: 200 mg PO BID x 7 days once per month, repeated 3x Fingernail involvement only: 200 mg BID PO x 7 days once per month, repeated 2x	Onychomycosis Tinea corporis, cruris, pedis, versicolor, capitis	<u>Contraindications:</u> CHF <u>Side effects:</u> Serious hepatotoxicity <u>Drug Interactions:</u> Inhibits CYP 3A4. Increases concentration of some drugs metabolized by this enzyme Give capsules with food, capsules must be swallowed whole

Table 31. Oral Therapies that are Important in Dermatology (continued)

Drug Name	Dosing Schedule	Indications	Comments
Ivermectin (Mectizan [®] , Stromectol [®])	200-250 µg/kg PO qwkly x 2 Take once as directed; repeat one week later	Onchocerciasis (USA only) Not licensed for use in Canada Also effective for: Scabies	No significant serious side effects Efficacious
Methotrexate (Trexall [®])	10-25 mg qwk, PO, IM, or IV Max: 30 mg/wk To minimize side effects, consider folic acid supplementation: 1 mg to 5 mg 6 days/week	Psoriasis Atopic dermatitis Lymphomatoid papulosis May also be effective in: Cutaneous sarcoidosis	<u>Monitoring strategies:</u> Baseline renal, liver, and hematological studies <u>Contraindications:</u> Pregnancy, lactation, alcohol abuse, liver dysfunction, immunodeficiency syndrome, blood dyscrasias, hypersensitivity to drug Restricted to severe, recalcitrant or disabling psoriasis not adequately responsive to other forms of therapy May be combined with cyclosporine to allow lower doses of both drugs
Minocycline (Minocin [®])	50-100 mg PO BID Taper to 50 mg PO OD as acne lessens	Acne vulgaris Rosacea	<u>Contraindications:</u> Caution if impaired renal or liver function <u>Drug interactions:</u> Do not use with isotretinoin (Accutane [®]) <u>Side effects:</u> Extensive; affects multiple organ systems including CNS, teeth, eyes, bones, renal, and skin (photosensitivity, and blue pigmentation) Alternative to tetracycline
Terbinafine (Lamisil [®])	250 mg PO OD x 2 weeks Fingernails x 6 wks Toenails x 12 wks Confirm diagnosis prior to treatment	Onychomycosis Tinea corporis, cruris, pedis, capitis	<u>Contraindications:</u> Pregnancy, chronic or active liver disease <u>Drug interactions:</u> Potent inhibitor of CYP 2D6; use with caution when also taking beta-blockers, certain anti-arrhythmic agents, MAOI type B, and/or antipsychotics Drug concentrates rapidly in skin, hair and nails at levels associated with fungicidal activity
Tetracycline	250-500 mg PO daily Taken 1 hour before or 2 hours after a meal	Acne vulgaris Rosacea Bullous pemphigoid	<u>Contraindications:</u> Severe renal or hepatic dysfunction Pregnancy/lactation

Imaging Modalities

X-Ray Imaging

Typical Effective Doses from Diagnostic Medical Exposures (in adults)*

Diagnostic Procedure	Equivalent Number of Chest x-rays	Approximate Equivalent Period of Natural Background Radiation** (~3 mSv/year)
X-ray examinations:		
Skull	5	12 days
Cervical spine	10	3 weeks
Thoracic spine	50	4 months
Lumbar spine	75	6 months
Chest (single PA film)	1	2 days
Shoulder	0.5	1 day
Mammography	20	7 weeks
Abdomen	35	3 months
Hip	35	3 months
Pelvis	30	10 weeks
Knee	0.25	<1 day
IVU	150	1 year
Dual x-ray absorptiometry (without/with CT)		
Upper GI series	0.5/2	<1 day/4 days
Small bowel series	300	2 years
Barium enema	250	20 months
	400	2.7 years
CT procedures:		
Head	100	8 months
Neck	150	1 year
Spine	300	2 years
Chest	350	2.3 years
Chest (pulmonary embolism)	750	5 years
Coronary angiography	800	5.3 years
Abdomen	400	2.7 years
Pelvis	300	2 years
Radionuclide studies:		
Brain (F-18 FDG)	705	4.7 years
Bone (Tc-99m)	315	2.1 years
Thyroid (Tc-99m)	240	1.6 years
Thyroid (I-123)	95	8 months
Cardiac rest-stress test		
(Tc-99m 1-day)	470	3 years
(Tc-99m 2-day)	640	4 years
Lung ventilation (Xe-133)	25	2 months
Lung perfusion (Tc-99m)	100	8 months
Renal (Tc-99m)	90 – 165	7 – 13 months
Liver-spleen (Tc-99m)	105	8.4 years
Biliary tract (Tc-99m)	155	1 year

**Calculated using average natural background exposure in Canada (Health Canada: <http://www.hc-sc.gc.ca/hl-vs/iyh-vsv/environ/expos-eng.php>)

- x-rays, or Roentgen rays, are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (process known as “attenuation”) and/or scattered
- the density of a structure determines its ability to attenuate or “weaken” the x-ray beam
 - air < fat < water < bone < metal
- structures that have high attenuation, e.g. bone, appear white on the resulting images
- two broad categories: plain films and computed tomography (CT)

Plain Films

- x-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- **contraindications:** pregnancy (relative)
- **advantages:** inexpensive, non-invasive, readily available
- **disadvantages:** radiation exposure, generally poor at distinguishing soft tissues

Computed Tomography (CT)

- x-ray beam opposite a detector moves in a continuous 360 degree arc as patient is advanced through the imaging system
 - subsequent computer assisted reconstruction of anatomical structures in the axial plane
- attenuation is quantified in Hounsfield units:
 - +1000 (bone) > +40 (muscle and soft tissue) > 0 (water) > -120 (fat) > -1000 (air)
- adjusting the “window width” (range of Hounsfield units displayed) and “window level” (midpoint value of the window width) can maximally visualize certain anatomical structures
 - e.g. CT chest can be viewed using “lung”, “soft tissue” and “bone” settings
- **contraindications:** pregnancy (relative), contraindications to contrast agents (e.g. renal failure)
- **advantages:** delineates surrounding soft tissues, excellent at delineating bones, excellent at identifying lung nodules/liver metastases, may be used to guide biopsies, spiral CT has fast data acquisition, helical CT allows 3D reconstruction, CT angiography is less invasive than conventional angiography
- **disadvantages:** high radiation exposure, IV contrast injection, anxiety of patient when going through scanner, higher cost than plain film, limited availability compared to plain films

Ultrasound (U/S)

- high frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright whereas hypoechoic structures appear dark on brightness-modulated images
- higher ultrasound frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
- **artifacts:** acoustic shadowing refers to the loss of information below an interface (e.g. gallstone) that strongly reflects sound waves; enhancement refers to the increase in reflection amplitude from objects that lie below a weakly attenuating structure (e.g. cyst)
- **Doppler:** determines the velocity of blood flowing past the transducer based on the Doppler effect
- **Duplex scan:** Doppler + visual images
- **advantages:** relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), determines cystic versus solid
- **disadvantages:** highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus

Magnetic Resonance Imaging (MRI)

- non-invasive technique that does not use ionizing radiation
- able to produce images in virtually any plane
- patient is placed in a magnetic field; protons (H+) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on which deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by a computer to generate MR images
- the MR image reflects the signal intensity as picked up by the receiver. This signal intensity is dependent on:
 1. hydrogen density: tissues with low hydrogen density (cortical bone, lung) generate little to no MR signal and appear black. Tissues with high hydrogen density (water) appear white on MRI
 2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment (see Table 1)

Table 1. Signal Intensities in T1- and T2-weighted MR Imaging

Tissue or Body Fluid	T1-weighted	T2-weighted
Gas	Nil	Nil
Mineral-rich tissue (e.g. cortical bone, calculi)	Nil	Nil
Collagenous tissue (e.g. ligaments, tendons, scars)	Low	Low
Hemosiderin	Low	Low
Fat	High	Medium to high
Protein-containing fluid (e.g. abscess, complex cyst)	Medium	High
Synovium	Medium	High
Nucleus pulposus	Medium	High
High bound-water tissues	Low	Low to medium
Muscle, hyaline cartilage		
Liver, pancreas, adrenal		
High free-water tissues	Low	High
CSF, urine, bile, edema		
Simple cysts		
GU organs, including kidney		
Thyroid		
Hemorrhage		
Hyperacute (<24 hours); hyperacute venous hemorrhage is slightly less bright than arterial on T2 due to deoxyhemoglobin	Low-intermediate	High
Acute (1–6 days) reflects deoxyhemoglobin	Low-intermediate	Low
Chronic (>7 days) reflects methemoglobin		
Intracellular	High	Low
Extracellular	High	High
Late reflects hemosiderin	Low-intermediate	Low
Neuropathology	Low	High
Ischemia		
Edema		
Demyelination		
Most malignant tumours		
Meningioma	Medium / Isointense	Medium / Isointense

Remember that water is "white" on T2 as "World War II"

Positron Emission Tomography Scans (PET)

- non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- nuclear medicine imaging technique that produces images of functional processes in the body
- positron-producing radioisotope, such as 18-fluorodeoxyglucose (18-FDG) is chemically incorporated into a metabolically active molecule (glucose), injected into patient, travels to target organ, accumulates in tissues of interest, and radioactive substance begins to decay, sending off gamma rays which are detected by PET scanner
- **advantages:** shows metabolism and function of tissues (not only anatomic), allows oncologic diagnosis, staging, restaging (lung, breast, colorectal, lymphoma, melanoma, esophageal, head and neck), has oncologic predictive and prognostic value (breast, lymphoma), can evaluate cardiac viability
- **disadvantage:** cost, ionizing radiation, lack of anatomic reference (unless used with CT/MRI)
- **contraindications:** pregnancy

Contrast Enhancement

Contrast Agents in X-Ray Imaging

- contrast media are used to examine structures that do not have inherent contrast differences relative to their surroundings
- contrast can be administered by mouth (anterograde), rectum (retrograde) or intravenous injection prior to x-ray imaging
- contrast agents include barium sulphate (GI studies), iodine (intravenous pyelogram (IVP), endoscopic retrograde cholangio-pancreatography (ERCP), hysterosalpingography) and gas (air or CO₂ used in GI double contrast exams)

Table 2. Types of Contrast Routes

	Advantages	Disadvantages	Contraindications
Suppository (Barium Enema)	Delineates intraluminal anatomy, may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ	Risk of contrast reaction; may cause renal failure in dehydrated patients with diabetes, myeloma or pre-existing renal disease	Previous adverse reaction to contrast, renal failure, multiple myeloma, dehydration, diabetes, severe heart failure; barium enema is also contraindicated in toxic megacolon, acute colitis, and suspected perforation (use Hypaque®)
IV Contrast	Same as above	Same as above	Previous adverse reaction to contrast, renal failure, multiple myeloma, dehydration, diabetes, severe heart failure

Acute Reactions to IV Contrast

Hot BUNS

Hypotension
Bradycardia
Urticaria
Nausea/vomiting
Seizures

Contrast Agents in MR Imaging

- gadolinium-chelates used to highlight the blood vessels or highly vascular structures (e.g. tumours)

Contrast Reactions

- contrast agents are generally safe; adverse reactions exist but they are uncommon
 - anaphylactoid reaction
 - contrast induced nephropathy
- treatment: diphenhydramine ± IV epinephrine

Chest Imaging

Chest X-Ray (CXR)

STANDARD VIEWS

- posteroanterior (PA):** patient stands erect with anterior chest against film plate to minimize distortion of the heart size
- lateral:** patient stands with arms above the head and left side against the film plate
 - better visualization of retrocardiac space and thoracic spine
 - more sensitive at picking up pleural effusions
 - helps localize lesions when combined with PA view
- anteroposterior (AP):** patient is supine with x-ray beam anterior
 - for bedridden patients (e.g. in ER, ICU or general ward)
 - enlarged cardiac silhouette and generally a lower quality film than PA
- lateral decubitus:** to assess for pleural effusion and pneumothorax in bedridden patients
- lordotic:** angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

Figure 1. CXR Views

Figure 2. Location of Fissures, Mediastinal Structures and Bony Landmarks

ANATOMY

Localizing Lesions

- **silhouette sign:** loss of normal interfaces due to lung pathology (consolidation, atelectasis, mass), which can be used to localize disease in specific lung segments
 - note that pleural or mediastinal disease can also produce the silhouette sign

APPROACH TO CXR

Basics

- ID: patient name, MRN, sex, age
- date of exam
- markers: R and/or L
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration, penetration and rotation

Analysis

- **tubes and lines:** check position and be alert for pneumothorax or pneumomediastinum
- **soft tissues:** neck, axillae, pectoral muscles, breasts/nipples, chest wall
 - nipple markers can help identify nipples (may mimic lung nodules)
 - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- **abdomen** (see *GI imaging*, DM11):
 - free air under the diaphragm
 - air fluid levels, distention in small and large bowels
 - herniation of abdominal contents
- **bones:** C-spine, thoracic spine, shoulders, ribs, sternum
 - lytic and blastic lesions and fractures
- **mediastinum:** trachea, heart, great vessels, mediastinum, spine
 - cardiac enlargement, tracheal shift, tortuous aorta, widened mediastinum
- **hila:** pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- **lungs:** lung parenchyma, pleura, diaphragm
 - lungs on lateral film should become darker when going inferiorly over the spine
 - comment on abnormal lung opacity, pleural effusions or thickening
 - right hemidiaphragm usually higher than left due to liver
 - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm

Table 3. Localization Using the Silhouette Sign

Interface Lost	Location of Lung Pathology
Superior vena cava/ right superior mediastinum	RUL
Right heart border	RML
Right hemidiaphragm	RLL
Aortic knob/ left superior mediastinum	LUL
Left heart border	Lingula
Left hemidiaphragm	LLL

Chest X-Ray Interpretation

Basics ABCDEF

- AP, PA or other view
- Body position/rotation
- Confirm name
- Date
- Exposure/quality
- Films for comparison

Analysis ABCDEF

- Airways, and hilar Adenopathy
- Bones and Breast shadows
- Cardiac silhouette and Costophrenic angle
- Diaphragm and Digestive tract
- Edges of pleura
- Fields (lung fields)

Figure 3. Location of Lobes of the Lung

Computed Tomography (CT) Chest

APPROACH TO CT CHEST

- **lung window**
 - central-trachea: patency, secretions
 - bronchial trees: anatomic variants, mucus plugs, airway collapse
 - lung parenchyma: fissures, nodules
- **bone window**
 - look at vertebrae, sternum, manubrium, ribs for fractures, lytic lesions, sclerosis
- **soft tissue window**
 - thyroid, chest wall, pleura
 - heart: chambers, coronary artery calcifications, pericardium
 - vessels: aorta, pulmonary artery, smaller vasculature
 - lymph nodes: mediastinal, axillary

TYPES OF CT CHEST

Table 4. Types of CT Chest

	Standard	High Resolution	Low Dose	CT Angiography
Advantage	Scans full lung very quickly (<1 minute)	Thinner slices provide high definition of lung parenchyma	1/5th the radiation	Iodinated contrast highlights vasculature
Disadvantage	Poor at evaluating diffuse disease	Only 5-10% lung is sampled	Decreased detail	Contrast can cause severe allergic reaction and is nephrotoxic
Contrast	±	No	No	Yes
Indication	CXR abnormality Pleural and mediastinal abnormality Lung cancer staging Follow up metastases Empyema vs. abscess	Hemoptysis Diffuse lung disease (e.g. sarcoidosis, hypersensitivity pneumonitis, pneumoconiosis) Pulmonary fibrosis Normal CXR but abnormal PFTs Characterize solitary pulmonary nodule	Screening Follow up infections, lung transplant, metastases	Pulmonary embolism Aortic aneurysms Aortic dissection

Figure 4. CT Thorax Windows

Lung Abnormalities

ATELECTASIS

- **pathophysiology:** collapse of alveoli due to restricted breathing, blockage of bronchi, external compression or poor surfactant
- **signs**
 - increased opacity of involved segment/lobe, silhouette sign
 - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
 - vascular crowding
 - compensatory hyperinflation of remaining normal lung
 - air bronchograms (also seen in consolidation)
- **differential**
 - **obstructive** (most common): air distal to obstruction is reabsorbed causing alveolar collapse
 - ♦ endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury) or mucous plug (seen in cystic fibrosis)
 - **compressive**
 - ♦ tumour, bulla, effusion, enlarged heart, lymphadenopathy
 - **traction (cicatrization):** due to scarring, which distorts alveoli and contracts the lung
 - **adhesive:** due to lack of surfactant
 - ♦ hyaline membrane disease, prematurity
 - **passive (relaxation):** a result of air or fluid in the pleural space
 - ♦ pleural effusion, pneumothorax
- **management:** in the absence of a known etiology, persisting atelectasis must be investigated (CT thorax) to rule out a bronchogenic carcinoma

DDx of Airspace Disease

- Pus (e.g. pneumonia)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma; lymphoma)
- Protein (e.g. alveolar proteinosis)

DDx of Interstitial Disease

- Pulmonary edema
- Collagen disease (e.g. fibrosis)
- Sarcoidosis
- Pneumoconiosis
- Metastatic disease (e.g. lymphangitic permeation)
- Inflammatory conditions (e.g. early viral pneumonia, interstitial pneumonia)

CONSOLIDATION

- **pathophysiology:** fluid (water, blood), inflammatory exudates, or tumour in alveoli
- **signs**
 - air bronchograms: lucent branching bronchi visible through opacification
 - airspace nodules: fluffy, patchy, poorly margined appearance with later tendency to coalesce, may take on lobar or segmental distribution
- **differential**
 - **fluid:** pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
 - **inflammatory exudates:** bacterial infections, TB, allergic hypersensitivity alveolitis, bronchiolitis obliterans organizing pneumonia (BOOP), allergic bronchopulmonary aspergillosis (ABPA), aspiration, sarcoidosis
 - **tumour:** bronchioalveolar carcinoma, lymphoma
- **management:** in the absence of a known etiology, persisting atelectasis must be investigated (CT thorax) to rule out a bronchogenic carcinoma

INTERSTITIAL DISEASE

- **pathophysiology:** pathological process involving the interlobular connective tissue (i.e. "scaffolding of the lung")
- **signs**
 - **linear:** fine lines caused by thickened connective tissue septae
 - ♦ Kerley A: long thin lines in upper lobes
 - ♦ Kerley B: short horizontal lines extending from lateral lung margin
 - ♦ Kerley C: diffuse linear pattern throughout lung
 - **nodular:** 1-5 mm well-defined nodules distributed evenly throughout lung
 - ♦ seen in malignancy, pneumoconiosis and with granulomas (sarcoidosis, miliary TB)
 - **reticular (honeycomb):** parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis
 - ♦ seen in interstitial pulmonary fibrosis (IPF), asbestosis and CVD
 - ♦ NOTE: watch for pneumothorax as a complication
 - **reticulonodular:** combination of reticular and nodular patterns
 - may also see signs of airspace disease (atelectasis and consolidation)
- **differential**
 - occupational/environmental exposure
 - ♦ inorganic: asbestosis, coal miner's pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
 - ♦ organic: bird fancier's lung, farmer's lung (moldy hay)
 - autoimmune: CVD, IBD, celiac disease, vasculitis
 - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, chemotherapy, heroin, cocaine, methadone
 - idiopathic: hypersensitivity pneumonitis, IPF, BOOP
- **management**
 - high resolution CT thorax
 - biopsy

PULMONARY NODULE (see Table 5)

- **signs:** round opacity ± silhouette sign
 - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- **differential**
 - **extrapulmonary density:** nipple, skin lesion, electrode, pleural mass, bony lesion
 - **solitary nodule:**
 - ♦ tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
 - ♦ inflammation: histoplasmosis, tuberculoma, coccidioidomycosis
 - ♦ vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
 - **multiple nodules:** metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, Wegener's disease)
- **management**
 - clinical information and CT appearance determine level of suspicion of malignancy
 - ♦ if high probability, invasive testing (fine needle aspiration, transbronchial/transsthoracic biopsy) is indicated
 - ♦ if low probability, repeat CXR or CT in 1-3 months and then every 6 months for 2 years; if no change, then >99% chance benign

**DDx for Cavitating Lung Nodule****WEIRD HOLES**

Wegener's syndrome
 Embolic (pulmonary, septic)
 Infection (anaerobes, pneumocystis, TB)
 Rheumatoid (necrobiotic nodules)
 Developmental cysts (sequestration)
 Histiocytosis
 Oncological
 Lymphangioleiomyomatosis
 Environmental, occupational
 Sarcoidosis

Table 5. Characteristics of Benign and Malignant Pulmonary Nodules

	Malignant	Benign
Margin	Ill-defined/spiculated ("corona radiata")	Well-defined
Contour	Lobulated	Smooth
Calcification	Eccentric or stippled	Diffuse, central, popcorn, concentric
Doubling Time	20-460 days	<20 days or >460 days
Other Features	Cavitation, collapse, adenopathy, pleural effusion, lytic bone lesions, smoking history	
Size	>3 cm	<3 cm
Cavitation	Yes, especially with wall thickness >15 mm, eccentric cavity and shaggy internal margins	No
Satellite Lesions	No	Yes

Figure 5. Pleural Effusion in Lateral View

Figure 6. Pneumothorax

**Elevated Hemidiaphragm Suggests:**

- Intra-abdominal process
- Pregnancy
- Diaphragmatic paralysis
- Atelectasis
- Lung resection
- Pneumonectomy

Pleural effusion also may result in apparent elevation.

Depressed Hemidiaphragm Suggests:

- Asthma
- COPD
- Large pleural effusion
- Tumour

Pulmonary Vascular Abnormalities

PULMONARY EDEMA

- **signs**
 - vascular redistribution/enlargement, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
 - edema fluid initially collects in interstitium:
 - ♦ loss of definition of pulmonary vasculature
 - ♦ peribronchial cuffing
 - ♦ Kerley B lines
 - ♦ reticulonodular pattern
 - ♦ thickening of interlobar fissures
 - as pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse air space disease often in a "bat wing" or "butterfly" pattern in perihilar regions with tendency to spare the outermost lung fields
- **differential:** cardiogenic (CHF), renal failure, volume overload, non-cardiogenic (ARDS)

PULMONARY EMBOLISM

- **signs:** Westermark sign (localized pulmonary oligemia), Hampton's hump (triangular peripheral infarct), enlarged RV and RA, pulmonary edema, atelectasis, pleural effusion
- **management:** V/Q scan, CT angiography (look for filling defect)

Pleural Abnormalities

PLEURAL EFFUSION

Table 6. Sensitivity of Plain Film Views for Pleural Effusion

X-ray Projection	Minimum Volume to Visualize
Lateral decubitus	25 mL – most sensitive
Upright lateral	50 mL – meniscus seen in the posterior costophrenic sulcus
PA	200 mL
Supine	Diffuse haziness

- a horizontal fluid level is seen only in a hydropneumothorax (both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis

PNEUMOTHORAX

- **signs**
 - upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
 - more obvious on expiratory (increased contrast between lung and air) or lateral decubitus film (air collects superiorly)
 - more difficult to detect on supine film; look for the "deep (costophrenic) sulcus" sign, "double diaphragm" sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
 - mediastinal shift may occur if air is under tension ("tension pneumothorax")
- **differential:** spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung

ASBESTOS

- asbestos exposure may cause various pleural abnormalities including benign plaques (most common) that may calcify, diffuse pleural fibrosis, effusion, and malignant mesothelioma

Mediastinal Abnormalities**Mediastinal Mass**

- the mediastinum is divided into three compartments; this provides the approach to the differential diagnosis of a mediastinal mass
- anterior (anterior line formed by anterior trachea and posterior border of heart and great vessels)
 - **4 T's:** thyroid, thymic neoplasm (e.g. thymoma), teratoma, and "terrible" lymphoma
 - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
- middle (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
 - esophageal carcinoma, esophageal duplication cyst
 - metastatic disease
 - lymphadenopathy (all causes)
 - hiatus hernia
 - bronchogenic cyst
- posterior (posterior to the middle line described above)
 - neurogenic tumour (e.g. neurofibroma, schwannoma)
 - multiple myeloma
 - pheochromocytoma
 - neuroenteric cyst, thoracic duct cyst
 - lateral meningocele
 - Bochdalek hernia
 - extramedullary hematopoiesis
- in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, and hematoma

**DDx Anterior Mediastinal Mass****4 Ts**

Thyroid
Thymus
Teratoma
"Terrible" lymphoma

**DDx of Increased Cardiothoracic Ratio**

- Cardiomegaly (myocardial dilatation or hypertrophy)
- Pericardial effusion
- Poor inspiratory effort/low lung volumes
- Pectus excavatum

ENLARGED CARDIAC SILHOUETTE

- heart borders
 - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
 - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
- cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
 - in an adult, good quality erect PA chest film, cardiothoracic ratio of >0.5 is abnormal
 - differential of ratio >0.5
 - ♦ cardiomegaly (myocardial dilatation or hypertrophy)
 - ♦ pericardial effusion
 - ♦ poor inspiratory effort/low lung volumes
 - ♦ pectus excavatum
 - ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
- pericardial effusion
 - globular heart
 - loss of indentations on left mediastinal border
 - peri- and epicardial fat pad separation on lateral film ("sandwich sign")
- right atrial enlargement
 - increase in curvature of right heart border
 - enlargement of SVC
- left atrial enlargement
 - straightening of left heart border
 - increased opacity of lower right side of cardiovascular shadow (double heart border)
 - elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and "double" heart border >7 cm, splayed carina (late sign)
- right ventricular enlargement
 - elevation of cardiac apex from diaphragm
 - anterior enlargement leading to loss of retrosternal air space on lateral
 - increased contact of RV against sternum
- left ventricular enlargement
 - displacement of cardiac apex inferiorly and posteriorly
 - "boot-shaped" heart
 - Rigler's sign: on lateral film, from junction of IVC and heart at level of the left hemidiaphragm, measure 1.8 cm posteriorly then 1.8 cm superiorly \rightarrow if cardiac shadow extends beyond this point, then LV enlargement is suggested
 - ♦ note: not to be confused with Rigler's sign in the abdomen

Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

Central Venous Catheter

- primarily used to administer fluids, medications, and vascular access for hemodialysis – also monitor central venous pressure (CVP)
- tip must be located distal to (above) right atrium as this prevents catheter from producing arrhythmias or perforating wall of atrium
 - if monitoring CVP – catheter tip must be proximal to venous valves
- tip of well positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle and inferiorly by top of RA
- course should parallel course of SVC – if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- **complications:** pneumothorax, bleeding (mediastinal, pleural), air embolism

Figure 7. Well Positioned Central Venous Catheter (CXR)

Endotracheal Tube

- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 4 cm above tracheal carina – avoids selective intubation of right/left mainstem bronchus as patient moves, low enough so it does not rub against vocal chords
- tube should not be inflated to the point that it continuously and completely occludes tracheal lumen as it may cause pressure induced necrosis of tracheal mucosa and predispose to rupture or stenosis
- maximum inflation diameter <3 cm – ensure diameter of balloon is less than tracheal diameter above and below balloon
- **complications:** aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

Nasogastric Tube (NG Tube)

- tip and sideport of NG tube should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- **complications:** aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

Swan-Ganz Catheter

- to monitor pulmonary capillary wedge pressure and to measure cardiac output in patients suspected of having left ventricular dysfunction
- tip of Swan-Ganz catheter should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- **complications:** pneumothorax, bleeding (mediastinal, pleural), air embolism

Chest Tube

- ideally placed to evacuate gas or fluid from pleural space
- gas tends to collect in nondependent portion of pleural space, while fluid lies in dependent portion
- chest tube to evacuate fluid usually in dorsal and caudal portion of pleural space
 - for pneumothoraces: ventral and cephalad portions of pleural space
- tube may lie in fissure as long as clinically performing function
- **complications:** lung perforation (mediastinal opacities)

Gastrointestinal (GI) Tract

Modalities

Abdominal X-Ray (AXR)

- indications:
 - acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction (SBO), large bowel obstruction (LBO)
 - chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
 - not useful in: GI bleed, chronic anemia, vague GI symptoms
- AXR – 3 most common views: supine, upright and left lateral decubitus (LLD)

3 Views of Abdomen

- Left lateral decubitus AXR
- Supine AXR
- Erect/Upright AXR

Table 7. Differentiating Small and Large Bowel

Property	Small Bowel	Large Bowel
Mucosal Folds	Uninterrupted valvulae conniventes (or plicae circularis)	Interrupted haustra extend only partway across lumen
Location	Central	Peripheral (picture frame)
Maximum diameter	3 cm	6 cm (9 cm at cecum)
Maximum fold thickness	3 mm	5 mm
Other	Rarely contains solid fecal material	Commonly contains solid fecal material

- abdomen divided into 2 cavities:
 - peritoneal cavity – lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
 - retroperitoneal cavity – contains duodenum (2nd, 3rd, and 4th parts), ascending and descending colon and the rectum, pancreas, kidneys, adrenal glands, ureters, bladder, psoas muscles, and the abdominal aorta; the contour of several of these organs can often be seen on radiographs

What's in the Retroperitoneum?

- Duodenum (2nd, 3rd, 4th part)
- Ascending, descending colon
- Rectum
- Kidneys, ureters, bladder, adrenals
- Psoas, quadratus lumborum
- Aorta, inferior vena cava

Abdominal CT

- plain CT: renal colic, hemorrhage
- contrast CT
 - IV contrast given immediately before or during CT to allow identification of arteries and veins
 - portal venous phase: indicated for majority of cases
 - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
 - oral contrast: barium or water soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
 - rectal contrast: given for investigation of colonic lesions
 - caution: contrast allergy (may premedicate with steroids and antihistamine)
 - contraindication: impaired renal function, based on eGFR

Approach to Abdominal X-Ray (AXR)

- mnemonic: “IT Free ABDO”
- I = identification:** date, name, MRN, age of patient, type of study
- T = technical factors:** good coverage, appropriate penetration, identify view
- Free = free fluid**
 - small amounts of fluid → increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
 - large amounts of fluid → diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
 - ascites and blood (hemoperitoneum) are the same density on the radiograph and therefore cannot be differentiated
- A = air**
 - volvulus (“twisting of the bowel upon itself”) – from most to least common:
 - sigmoid: “coffee bean” sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal large bowel dilation
 - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
 - gastric: rare
 - small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
 - toxic megacolon
 - manifestation of fulminant colitis
 - extreme dilatation of colon (>6.5 cm) with mucosal changes including foci of edema, ulceration and pseudopolyps, loss of normal haustral pattern

Approach to AXR

IT Free ABDO

- Identification
- Technical factors
- Free fluid
- Air
- Bowel wall thickening
- Densities (bones, calcifications)
- Organs

Table 8. Abnormal Air on Abdominal X-Ray

Air	Appearance	Common Etiologies
Extraluminal		
Intraperitoneal (pneumoperitoneum)	Upright film: air under diaphragm LLD film: air between liver and abdominal wall supine film: gas outlines of structures not normally seen: <ul style="list-style-type: none"> • Inner and outer bowel wall (Rigler's sign) • Falciform ligament • Peritoneal cavity ("football" sign) 	Perforated viscus Postoperative (up to 10 days to be resorbed)
Retroperitoneal	Gas outlining retroperitoneal structures allowing increased visualization: <ul style="list-style-type: none"> • Psoas shadows • Renal shadows 	Perforation of retroperitoneal segments of bowel: duodenal ulcer, post-colonoscopy
Intramural (pneumatosis intestinalis)	Lucent air streaks in bowel wall, 2 types: <ol style="list-style-type: none"> 1. Linear 2. Rounded (cystoides type) 	1. Linear: ischemia, necrotizing enterocolitis 2. Rounded/cystoides (generally benign): primary (idiopathic), secondary to COPD
Intraluminal	Dilated loops of bowel, air-fluid levels	Adynamic (paralytic) ileus, mechanical bowel obstruction (see Table 9)
Loculated	Mottled, localized in abnormal position without normal bowel features	Abscess (evaluate with CT)
Biliary	Air centrally over liver	Sphincterotomy, gallstone ileus, erosive peptic ulcer, cholangitis, emphysematous cholecystitis
Portal Venous	Air peripherally over liver in branching pattern	Bowel ischemia/infarction

**Biliary vs. Portal Venous Air**

"Go with the flow": air follows the flow of bile or portal venous blood.

Biliary air is most prominent centrally over the liver.

Portal venous air is most prominent peripherally.

Table 9. Adynamic Ileus vs. Mechanical Obstruction

Feature	Adynamic Ileus	Mechanical Obstruction
Calibre of Bowel Loops	Normal or dilated	Usually dilated
Air-Fluid Levels (erect and LLD films only)	Same level in a single loop	Multiple air fluid levels giving "step ladder" appearance, dynamic (indicating peristalsis present) "string of pearls" (row of small gas accumulations in the dilated valvulae conniventes)
Distribution of Bowel Gas	Air throughout GI tract generalized or localized <ul style="list-style-type: none"> • In a localized ileus (e.g. pancreatitis, appendicitis): dilated "sentinel loop" remains in the same location on serial films, usually adjacent to the area of inflammation 	Dilated bowel up to the point of obstruction (i.e. transition point) No air distal to obstructed segment "Hairpin" (180°) turns in bowel

- **B = bowel wall thickening**

- increased soft tissue density in bowel wall, thumb-like indentations in bowel wall ("thumb-printing"), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
- may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage

- **D = densities**

- bones – look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
- abnormal calcifications – approach by location
 - ♦ RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
 - ♦ RLQ: ureteral stone, appendicolith, gallstone ileus
 - ♦ LUQ: renal stone, adrenal calcification, tail of pancreas
 - ♦ LLQ: ureteral stone
 - ♦ central: aorta/aortic aneurysm, pancreas, lymph nodes
 - ♦ pelvis: phleboliths (calcified veins), uterine fibroids, bladder stones

- **O = organs**

- kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
- outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

Approach to Abdominal Computed Tomography (CT)

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually, from top to bottom evaluating size and shape of each area of increased or decreased density
- evaluate the following
 - soft tissue window
 - ♦ liver, gallbladder, spleen and pancreas
 - ♦ adrenals, kidneys, ureters and bladder
 - ♦ stomach, duodenum, small bowel mesentery and colon/appendix
 - ♦ retroperitoneum: aorta, vena cava and mesenteric vessels; look for adenopathy in vicinity of vessels
 - ♦ peritoneal cavity for fluid or masses
 - ♦ abdominal wall and adjacent soft tissue
 - lung window
 - ♦ visible lung (bases)
 - bone window
 - ♦ vertebrae, spinal cord, and bony pelvis

Ileocecal Valve (ICV) Function in Large Bowel Obstruction

Competent ICV

Distention of large bowel between obstruction and ICV; small bowel unaffected

Higher risk of perforation, especially with cecal distention > 10 cm

Incompetent ICV

Distention of large and small bowel

CT and Bowel Obstruction

- cause of bowel obstruction rarely found on plain films – CT is best choice for imaging

CT Colonography (virtual colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- CT scan of the abdomen after the instillation of air into a prepped colon
- computer rendering of 2D CT images into a 3D intraluminal view of the colon in order to look for masses
- lesions seen on 3D rendering masses correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of identified colonic lesions

Contrast Studies

Table 10. Types of Contrast Studies

Study	Description	Indications	Assessment	Diseases
Cine Esophagogram	Contrast agent swallowed Recorded for later playback and analysis	Dysphagia, swallowing incoordination, recurrent aspiration, post-op cleft palate surgery	Cervical esophagus	Aspiration, webs, Zenker's diverticulum, cricopharyngeal bar, laryngeal tumour
Barium Swallow	Contrast agent swallowed under fluoroscopy, selective images captured	Dysphagia, r/o GERD, post esophageal surgery	Thoracic esophagus	Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear
Upper GI Series	Double contrast study 1) Barium to coat mucosa, then 2) Gas pills for distention Patient NPO after midnight	Dyspepsia, investigate possible UGI bleed, weight loss/anemia, post gastric surgery	Thoracic esophagus, stomach, duodenum	Ulcers, neoplasms, filling defects
Barium Enema	Colon filled retrograde with barium and air or CO ₂ Bowel prep the night before procedure	Altered bowel habits, suspected LGI bleed, weight loss, anemia, r/o large bowel obstruction, suspected perforation, check surgical anastomosis, history of polyps	Large bowel Rectum may be obscured by tube – therefore must do sigmoidoscopy to exclude rectal lesions	Diverticulosis, neoplasms, IBD, intussusception (can be reduced with barium or air enema), volvulus
Hypaque® Enema	Water soluble contrast with or without bowel prep	Post operatively to assess anastomoses for leak/obstruction, perforation	Large bowel	Perforation, obstruction
Small Bowel Follow Through	Single contrast images following UGI series	GI bleed with nondiagnostic upper GI series/barium enema, weight loss/anemia, diarrhea, IBD, malabsorption, abdominal pain, post small bowel surgery	Entire small bowel	Neoplasms, IBD, malabsorption, infection
Small Bowel Enema (enteroclysis)	Duodenal intubation 1) Barium/methyl cellulose infusion and fluoroscopic evaluation 2) CT enteroclysis with water infusion	IBD, malabsorption, weight loss/anemia, Meckel's diverticulum	Entire small bowel	Neoplasms, IBD, malabsorption, infection

Normal liver appears more dense than spleen on CT. If less dense, suspect fatty infiltration.

Liver Mass DDx
5 Hs
HCC
 Hydatid cyst
 Hemangioma
 Hepatic adenoma
 Hyperplasia (focal nodular)

Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease

Archives of Internal Medicine 1998; 154(22):2573-81.

Purpose: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including ultrasonography, oral cholecystography, radionuclide scanning with Technetium, MRI, CT.

Study Characteristics: Meta-analysis of 30 studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease.

Participants: No limits.

Main Outcomes: Sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 month clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.

Results: For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI, 0.95 to 0.99) and specificity (0.95, 95% CI, 0.88 to 1.00) and adjusted (for verification bias) sensitivity (0.84; 95% CI, 0.76 to 0.92) and specificity (0.99; 95% CI, 0.97 to 1.00). For evaluating acute cholecystitis, radionuclide scanning has the best sensitivity (0.97; 95% CI, 0.96 to 0.98) and specificity (0.90; 95% CI, 0.86 to 0.95).

Conclusions: U/S is the test of choice for diagnosing cholelithiasis and radionuclide scanning is the superior test for diagnosing acute cholecystitis.

Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents

Annals of Internal Medicine 2004; 141(7):537-546

Purpose: To review the diagnostic accuracy of CT and ultrasonography in the diagnosis of acute appendicitis.

Study Characteristics: Meta-analysis of 22 prospective studies evaluating the use of CT or ultrasonography, followed by surgical or clinical follow-up in patients with suspected appendicitis.

Participants: Age 14 and older with a clinical suspicion of appendicitis.

Main Outcomes: Sensitivity and specificity using surgery or clinical follow-up as the gold standard. Results: CT (12 studies) had an overall sensitivity of 0.94 (95% CI, 0.91 to 0.95) and a specificity of 0.95 (95% CI, 0.93 to 0.96). Ultrasonography (14 studies) had an overall sensitivity of 0.86 (95% CI, 0.83 to 0.88) and a specificity of 0.81 (95% CI, 0.78 to 0.84).

Conclusions: CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

Specific Visceral Organ Imaging

Liver

- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT or MRI \pm IV contrast: differentiation of benign hemangiomas from primary liver tumours [hepatocellular carcinoma (HCC)] and metastases, cirrhosis, portal hypertension
- findings
 - altered liver size, contour, density
 - fatty infiltration: decreased liver density
 - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
 - varices (caput medusa, esophageal varices, porto-systemic shunts, dilated splenic vein)
 - splenomegaly and ascites
- investigation of liver masses
 - require contrast to visualize certain hepatic masses
 - 3 phases of enhancement following IV contrast bolus
 - ♦ arterial phase (20-30 sec)
 - early and late arterial phase possible on multidetector CT
 - late arterial phase best for discriminating hypervascular HCC
 - ♦ portal venous phase (60-70 sec)
 - provides maximum enhancement of hepatic tissue
 - most tumours supplied by hepatic artery and relatively hypovascular, therefore, appear as low-attenuation masses in portal venous phase
 - ♦ equilibrium phase (120-180 sec)

Table 11. Imaging of Liver Masses

Mass	U/S	CT
Metastases	Multiple masses of variable echotexture	Usually low attenuation on contrast enhanced scan
HCC	Single/multiple masses, or diffuse infiltration	Small: hypervascular enhances in arterial phase Large: low-attenuation
Simple Cyst	Well-defined, anechoic, acoustic enhancement	Well-defined, low attenuation, homogenous
Abscess	Poorly defined, irregular margin, hypoechoic contents	Low-attenuation lesion with an irregular enhancing wall
Hydatid Cyst	Simple/multiloculated cyst	Low-attenuation simple or multiloculated cyst; calcification
Hemangioma	Homogenous hyperechoic mass	Peripheral globular enhancement in arterial phase scans; central-filling and persistent enhancement on delayed scans
Focal Nodular Hyperplasia	Well-defined mass, central scar seen in 50%	Equal attenuation to liver in portal venous phase, enhancement in arterial phase
Hepatic Adenoma	Most common in young women taking oral contraceptives. Well-defined mass with hyperechoic areas due to hemorrhage	Well-defined margin with heterogeneous texture due to hemorrhage or fat

Spleen

- U/S, CT, and/or nuclear medicine scan
- primary lymphoma > splenic metastases
- CT for splenic trauma (hemorrhage)

Biliary Tree

- U/S
 - bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT
 - dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- ERCP, MRCP, PTC: further evaluation of obstruction and possible intervention

Pancreas

- tumours
 - U/S: mass is more echogenic than normal pancreatic tissue
 - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
 - MRCP: imaging of ductal system using MRI cholangiography
 - ERCP: assessment of pancreatic and bile ducts via Ampulla of Vater; therapeutic potential (stent placement, stone retrieval); complication of acute pancreatitis occurs in 5% of diagnostic procedures and 10% of therapeutic procedures
- pancreatitis and/or its complications: pseudocyst, abscess, necrosis, splenic artery aneurysm (see "itis" Imaging, DM15)

"itis" Imaging

Acute Cholecystitis

- U/S very accurate – thick wall, pericholecystic fluid, gallstones, dilated gallbladder, positive sonographic Murphy's sign
- nuclear medicine (HIDA scan) may be helpful in equivocal cases, but is not often used
 - equivalent sensitivity and specificity to ultrasound

Acute Appendicitis

- U/S very useful – thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible
- U/S may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
- CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage

Acute Diverticulitis

- most common site is rectosigmoid (diverticula are outpouchings of colon wall)
- CT is imaging modality of choice, although U/S is sometimes used
 - oral and rectal contrast given before CT to opacify bowel
 - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
 - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
 - sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow up with colonoscopy)
 - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)

Acute Pancreatitis

- clinical/biochemical diagnosis
- imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
- U/S good for screening and follow-up of a hypoechoic enlarged pancreas (although useless if ileus present as gas obscures pancreas)
- CT is useful in advanced stages of pancreatitis and in assessing for complications and is increasingly becoming the 1st line imaging test
 - enlarged pancreas, edema, stranding changes in surrounding fat with indistinct fat planes, mesenteric and Gerota's fascia thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
 - CT-guided needle aspiration and/or drainage done for abscess when clinically indicated
 - pseudocyst may be followed by CT and drained if symptomatic

Angiography of GI Tract

- GI tract arterial blood supply
 - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
 - superior mesenteric artery (SMA): jejunal, ileal, ileo-colic, right colic, middle colic
 - inferior mesenteric artery (IMA): left colic, superior rectal
- imaging of GI tract vessels
 - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
 - ♦ flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
 - CT angiogram: non-invasive using IV contrast (no catheterization required)

Genitourinary System

Modalities

KUB (kidneys, ureters, bladder)

- a frontal supine radiograph of the abdomen
- useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir), as well as indwelling ureteric stents or catheters
- addition of intravenous contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

Imaging Modality Based on Presentation

- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloating = U/S, CT
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = Hysterosalpingogram, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram

Figure 8. Triphasic CT of an Angiomyolipoma – showing fat density with non-contrast scan, mildly enhancing with contrast

Figure 9. Triphasic CT of a Renal Cell Carcinoma – showing arterial enhancement and venous de-enhancement

Figure 10. Retrograde Urethrogram – demonstrating stricture in the membranous urethra

Abdominal CT

• plain CT

- good for general imaging of renal anatomy, although specific study types have supplanted plain CT for many indications, including CT urography (upper tract uroepithelial malignancies and renal calculi) and triphasic CT (renal masses)

• CT urography

- excretory phase imaging allows detailed assessment of urinary tracts
- high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts
- also useful for assessment of renal calculi

• triphasic CT

- standard imaging for renal masses
- comprised of unenhanced, nephrographic, and excretory phases
- allows accurate assessment of renal arteries and veins and better characterization of suspicious renal masses, with particular utility in differentiating renal cell carcinoma from more benign masses

U/S

- initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts)
- technique of choice for screening patients with suspected hydronephrosis (no intravenous contrast injection, no radiation to patient, and can be used in patients in renal failure)
- solid renal masses: echogenic (bright on U/S)
- cystic renal masses: smooth well-defined walls with anechoic interior (dark on U/S)
- complicated cysts: internal echoes within a thickened, irregular-walled cyst
- transrectal U/S (TRUS) useful to evaluate prostate gland and guide biopsies
- Doppler U/S to assess renal vasculature

Retrograde Pyelography

- used to visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium
- ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
- only yields information about the collecting systems (renal pelvis and associated structures)
 - no information regarding the parenchyma of the kidney

Voiding Cystourethrogram (VCUG)

- bladder filled with contrast to the point where voiding is triggered
- real-time images via fluoroscopy (continuous x-ray imaging) to visualize bladder
- contractility and evidence of vesicoureteric reflux
- indications: children with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction or vesicoureteral reflux

Retrograde Urethrogram

- used mainly to study strictures or trauma to the male urethra (Figure 10)

MRI

- strengths: high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
- indicated over CT for depiction of renal masses in patients with previous nephron sparing surgery, patients requiring serial follow-ups (less radiation dosage), patients with reduced renal function, and patients with solitary kidneys

Renal Scan

- 2 radionuclide tests for kidney – renogram and morphological scan
- renogram
 - to assess renal function and collecting system
 - useful in evaluation of renal failure, workup of urinary tract obstruction and hypertension, investigation of renal transplant
 - intravenous injection of a radionuclide, technetium-99m pentetate (Tc99m-DTPA) or iodine-labeled hippurate, and imaged at 1-second intervals with a gamma camera over 30 minutes to assess perfusion
 - ♦ delayed static images over the next 30 minutes can be used to assess renal function and the collecting system
- morphological
 - to assess renal anatomy
 - study done with Tc99m-DMSA and Tc99m-glucoheptonate
 - useful in investigation of renal mass and cortical scars

Gynecological Imaging

U/S

- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air containing loops of bowel
 - good initial investigation for suspected pelvic pathology
- transvaginal approach provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
 - improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram

- useful for assessing pathology of the uterine cavity and fallopian tubes, performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- particularly useful for evaluating uterine abnormalities (bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

CT/MRI

- excellent for evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies

Selected Pathology

Renal Masses

- Bozniak classification for cystic renal masses
 - classes I-II are benign and can be disregarded
 - class IIF should be followed
 - classes III-IV are suspicious for malignancy, requiring additional workup

Table 12. Bozniak Classification for Cystic Renal Masses

Classes	Definition
Simple renal cysts	
Class I	Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hair thin wall
Class II	Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (<3 cm) that do not enhance with contrast
Complex renal cysts	
Class III	Thick irregular walls, \pm calcifications, \pm septated, enhancing walls or septa with contrast
Renal cell carcinoma	
Class IV	Same as class III + soft tissue enhancement with contrast (defined as >10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase \pm areas of necrosis

- angiomyolipoma (a benign renal neoplasm composed of fat, vascular, and smooth muscle elements)
 - fat density seen on non-contrast CT (<-10 Hounsfield units), some enhancement with contrast (less than renal cell carcinoma)

Neuroradiology

Modalities

- CT is modality of choice for most neuropathology; even under circumstances when MRI is preferred, CT is frequently the initial study because of its speed, availability and lower cost
- CT is preferred for
 - acute head trauma: CT is best for visualizing "bone and blood"; MRI is used in this setting only when CT fails to detect an abnormality in the presence of strong clinical suspicion
 - acute stroke (MR ideal, CT most frequently used)
 - suspected subarachnoid or intracranial hemorrhage
 - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
 - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumours, respectively

Skull Films

- rarely performed; CT is modality of choice
- indications include
 - screening for destructive bony lesions (e.g. metastases)
 - metabolic disease
 - skull anomalies
 - post-operative changes/post-operative confirmation of hardware placement
 - skeletal surveys
- generally not indicated for non-penetrating head trauma

Figure 11. Transabdominal Ultrasound – pregnancy, 18 wk fetus

Figure 12. Hysterosalpingogram – showing left hydrosalpinx

Pregnancy should always be ruled out by beta-HCG before CT of a female pelvis (or any organ system) is performed.

Attenuation
Bone (= bright) > grey matter > White matter ("fatty" myelin) > CSF > air (= dark)

Modality Based on Presentation

- Cognitive decline = CT
- Cord compression = MRI
- Decreased LOC = CT
- Fish bone = CT
- LBP, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- R/O bleed = CT
- R/O aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

DDx for Ring Enhancing Lesion on CT with Contrast

MAGICAL DR

*Metastases
*Abscess
*Glioblastoma (high grade astrocytoma)
Infarct
Contusion
AIDS
Lymphoma
Demyelination
Resolving hematoma

[* by far the 3 most common Dx's]

Figure 13. Epidural Hematoma

Figure 14. Subdural Hematoma

Figure 15. Subarachnoid Hematoma

CT

- excellent study for evaluation of bony abnormalities
- often done first without and then with intravenous contrast to show vascular structures or anomalies
- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
 - when in doubt, look for circle of Willis or confluence of sinuses to determine presence of contrast enhancement
- posterior fossa can be obscured by extensive bony artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with newer generation of CT scanners

Myelography

- introduction of water-soluble, low-osmotic-contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
- excellent study for disc herniations, traumatic nerve root avulsions
- use has decreased due to MRI

MRI (see Table 1)

- shows brain and spinal soft tissue anatomy in fine detail
- clearly distinguishes white from grey matter (especially T1-weighted series)
- multiplanar reconstruction helpful in pre-op assessment

Cerebral Angiography/CT Angiography/MR Angiography

- evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
- conventional digital subtraction angiography (DSA) remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm)
- MR angiography (MRA) methods (phase contrast, time of flight, gadolinium-enhanced) and CT angiography (CTA) are much less invasive without actual risk to intracranial or neck vessels
- MRA and CTA are often used first as 'screening tests' for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

Nuclear Medicine

- SPECT using HMPAO (technetium-99m labelled derivative of propylamine oxane) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within cells
- PET imaging assesses cerebral metabolic activity

Approach to CT Head

- think anatomically, work from superficial to deep
- **scan** – confirm that the imaging is of the patient of interest, whether contrast was used, if the patient is aligned properly, if there is artifact present
- **skin/soft tissue** – examine the soft-tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also investigate: ear, orbital contents (globe, fat, muscles), parotid, muscles of mastication (masseter, temporalis, pterygoids), visualized pharynx
- **bone and airspace** (use the bone window) – check calvarium, visualized mandible, visualized c-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture
- **dura and subdural space** – look for crescent-shaped hyperdensity in the subdural space as evidence of subdural hematoma; look for a lentiform hyperdensity in epidural space as evidence of epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- **parenchyma** – look for symmetry of the parenchyma for evidence of midline shift; look for poor contrast between grey and white matter as evidence of possible infarction, tumour, edema, infection, or contusion; look for hyperdensities in the parenchyma suggestive of enhancing lesions, intracerebral hemorrhage, or calcification; central grey matter nuclei should be visible, including globus pallidus, putamen, and internal capsule, otherwise suspect infarct, tumour, or infection
- **ventricles/sulci/cisterns** – examine position of ventricles for evidence of midline compression/shift; look for hyperdensities in the ventricles indicative of ventricular/subdural hemorrhage; look at ventricular size for evidence of hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour

Approach to the CT Head

Some = Scan
Sore = Skin/Soft Tissue
Brains = Bone/Airspace
Demonstrate = Dura/Subdural space
Pushed = Parenchyma
Ventricles = Ventricles/Sulci/Cisterns

Transient ischemic attacks are not associated with radiological findings.

DDx Suspected MS lesion

Vasculopathy: ischemia, vasculitis, hypertension, migraine
Demyelinating disease: progressive multifocal leukoencephalopathy, age-related
Inflammatory process: sarcoid, lyme, primary/metastatic cancer

Selected Pathology

- see Neurosurgery, NS4-23 for intracranial mass lesions
- see Neurosurgery, NS29-36 and Plastic Surgery, PL26 for head trauma
- see Emergency Medicine, ER7 for vertebral trauma
- see Neurosurgery, NS22-29 and Orthopaedics, OR22 for degenerative spinal abnormalities

CEREBROVASCULAR DISEASE (see Neurology, N44-48 and Neurosurgery, NS17-22)

- carotid artery disease
 - evaluate with Duplex Doppler U/S
 - MR angiography or CT angiography if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)
- infarction
 - early changes
 - ♦ CT
 - usually normal within 6 hours of infarction
 - edema (loss of grey-white matter differentiation – “insular ribbon” sign, effacement of sulci, mass effect)
 - within 24 hours, development of low-density, wedge-shaped area of infarction extending to periphery (correlating to vascular territory distal to affected artery)
 - refer to **Functional Neuroanatomy software** (online)
 - in case of ischemic stroke, may see hyperattenuating (bright) artery (hyperdense MCA sign) represents intravascular thrombus or embolus
 - in case of hemorrhagic stroke or transformation (common in basal ganglia and cortex), may see bright acute blood surrounded by edema
 - ♦ MRI
 - edema with high signal on T2-weighted images and FLAIR (fluid-attenuated inversion-recovery) image (loss of grey-white matter differentiation, effacement of sulci, mass effect)
 - diffusion-weighted image (DWI) shows acute high signal changes demonstrating restricted movement of water (indicative of cytotoxic edema)
 - apparent diffusion coefficient (ADC) image shows low signal intensity in acute ischemia (nadir 3-5 days, returns to baseline 1-4 weeks)
 - subacute changes (CT and MRI)
 - ♦ edema and mass effect more prominent
 - ♦ gyral enhancement with contrast indicative of blood-brain barrier breakdown
 - chronic changes (CT and MRI)
 - ♦ encephalomalacia (parenchymal volume loss) with dilatation of adjacent ventricles

Multiple Sclerosis (MS)

- acute phase: plaques undergo inflammatory reaction with edema, cellular infiltration, and spectrum of demyelination
- chronic phase: astrocytic hypoplasia, resolution of cellular inflammation, and loss of myelin
- MRI is the most sensitive diagnostic test (>90%), but not specific
 - ischemic demyelination can produce similar features
 - confluent multiple sclerosis lesions can be mistaken for a neoplasm
 - specificity greatly improved if periventricular plaques are accompanied by lesions in the cerebellum, cerebral peduncles, corpus callosum, and spinal cord
- T2-weighted MRI shows multiple hyperintense round or ovoid white matter plaques from myelin breakdown in periventricular or subcortical distribution
- “Dawson’s fingers” are seen as radiating, elongated areas of T2 signal extending from the ventricles; these represent demyelination along medullary veins (Figure 18)
- T1-weighted MRI shows iso- or low intensity regions (“black-holes”)
- most common locations include periventricular white matter (>80%), corpus callosum (particularly at callosal-septal interface, 50-80%), visual pathways (optic neuritis), posterior fossa, and brainstem
- FLAIR imaging superior for supratentorial white matter lesions; may not detect posterior fossa, brainstem, and spinal lesions
- enhancement lasts 2-8 weeks but may persist for 6+ months; clinical suspicion for neoplasm required if nodule/plaque enhances for 3+ months
- lesions tend to be confluent and >6 mm in diameter
- new lesions with active demyelination may enhance with gadolinium contrast, ranging from nodular enhancement to ring or arc shaped; older, less active lesions do not enhance

Early Signs of Brain Infarction at CT: Observer Reliability and Outcome after Thrombolytic Treatment – Systematic Review

Radiology 2005; 235:444-453

Study: Systematic review of 15 studies between 1990-2003 that investigated inter-observer agreement of early CT signs of acute ischemic stroke, and prognostic value of early CT signs in patient outcome. There was a median of 30 CTs and 6 raters per study.

Patients: 3468 adult patients who underwent CT within 6 hours of stroke.

Main Outcome: Degree of inter-observer agreement between stroke signs on CT, and risk of death or dependency (using validated stroke scales) based on CT signs using after 1-3 months.

Results: Prevalence of all early infarction signs was $61\% \pm 21$, and interobserver agreement was 0.14-0.78 (K statistic) for any early infarct sign. Average sensitivity of detecting early ischemic stroke was 66% (range 20%-87%) and average specificity was 87% (range 56%-100%). Experience improved detection, but knowledge of patient history did not. An increased risk of poor outcome (death or dependency) was associated with any early infarction sign, with an odds ratio of 3.11 (95%CI, 2.77-3.49).

Figure 16. CT Images of Early Infarct – showing (A) absence of left insular ribbon (B) hyperdense artery

Figure 17. Diffusion Weighted Imaging of Patient with Normal CT – demonstrates right frontotemporal infarct

Figure 18. T2-weighted FLAIR
– (A) sagittal (B) axial images of multiple sclerosis with periventricular “Dawson’s Fingers”

Figure 19. T2-weighted (FLAIR)
Coronal Image of HSV Encephalitis
Affecting Temporal Lobes

CNS Infections

• leptomeningitis

- inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood brain barrier (choroid plexus or circumventricular organs)
- pathogens include: *S. pneumoniae*, *H. influenza*, *N. meningitidis*, *L. monocytogenes*
- best visualized with MRI (T2-weighted/FLAIR) over CT
- findings include
 - ♦ meningeal enhancement (following the gyri/sulci, and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
 - ♦ a normal MRI does not rule out leptomeningitis

• herpes simplex encephalitis (see [Infectious Diseases](#), ID6)

- inflammation of the brain parenchyma secondary to HSV infection
- asymmetrically affects the temporal lobes, orbitofrontal region, insula, and cingulate gyrus
- best imaged with MRI (T1- and T2-weighted imaging)
- findings include
 - ♦ acute (within 4-5 days): high intensity lesions on T2 MRI in temporal and inferior frontal lobes, asymmetric
 - strongly suggestive of HSV encephalitis
 - DDx: infarct, tumour, status epilepticus, limbic encephalitis
 - ♦ CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
 - ♦ long term may show parenchymal loss to affected areas

• cerebritis/cerebral abscess

- an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms
- commonly located in the distribution of the middle cerebral artery
- pathogens include: *S. aureus* (often in IVDU, nosocomial), GN bacteria, *Streptococcus*, *Bacteroides*
- findings according to one of four stages of abscess formation:
 - ♦ early cerebritis (1-3 days) – inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
 - ♦ late cerebritis (4-9 days) – ring enhancement may be present
 - ♦ early capsule (10-13 days) – ring enhancement
 - ♦ late capsule (14 days or greater) – well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperdensity on T2

Musculoskeletal System (MSK)

Modalities

Plain Film/X-Ray

- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malalignment, assessment of orthopedic hardware, initial assessment of bone tumours
- minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- image proximal and distal joints (particularly important with paired bones, e.g. radius/ulna)
- not very effective in evaluating soft tissue injury
- strengths: fast, inexpensive, readily available, reproducible

CT

- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification
- strengths: fast, reproducible, excellent bone evaluation, and spatial resolution
- drawbacks: radiation dose, relatively poor soft tissue characterization in comparison with U/S and MRI

MRI

- indications: evaluation of internal derangement of joints (ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses
- strengths: excellent soft tissue contrast, multiplanar imaging, no radiation
- drawbacks: long imaging times, expense, claustrophobia, contraindications (e.g. pacemakers, orbital metallic bodies), artifact around metal hardware

Plain Film First for Fractures
CT for Cortex
MRI for Marrow

Approach to Fractures

1. Look for soft tissue swelling
2. Look for fracture lines (abnormal black lines)
3. Look for discontinuation/disruption of cortex
4. Look for displacement and angulation
5. Look for fracture extension into the joint

See [Orthopaedics](#), OR5

Ultrasound

- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, ultrasound guided biopsy and injections
- Doppler – determines vascularity of structures
- strengths: good soft tissue evaluation, easy contralateral comparison, dynamic imaging
- weaknesses: operator dependent, steep learning curve, poor for bone evaluation

Nuclear Medicine (Skeletal Scintigraphy)

- determine the location and extent of bony lesions
- radioisotopes localize to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget's), sites of reactive bone formation, and periostitis
- very sensitive, not specific (trauma, infection, inflammation look similar)

Approach to Interpretation of Bone X-Rays

- identification – name, MRN, age of patient, type of study, region of investigation
- soft tissues – swelling, calcification/ossification
- joints – alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone – periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions (Figure 20)

Trauma

Fracture/Dislocation

- description of fractures
 - patient (name, MRN, age, sex)
 - views (e.g. AP and lateral of right wrist)
 - site of fracture
 - ♦ bone (e.g. tibia, scaphoid, etc.)
 - ♦ region of bone (e.g. proximal, distal, metaphyseal, epiphyseal, diaphyseal)
 - ♦ intra-articular vs. extra-articular
 - pattern of fracture line
 - ♦ simple: a single break divides bone in two pieces
 - ♦ comminuted: bone broken into more than two pieces
 - displacement (distal fragment with reference to the proximal fragment)
 - soft tissue involvement
 - ♦ calcification, gas, foreign bodies
 - ♦ open (compound) vs. closed
 - ♦ type of fracture
 - stress: fracture due to repetitive trauma
 - pathologic: fracture in area of bone weakened by disease
- for specific fracture descriptions and characteristics of fractures, see [Orthopaedics](#), OR5

Types of Fractures

- Transverse
- Oblique
- Spiral
- Avulsion
- Impacted

Types of Displacements

- Translation
- Angulation
- Rotation
- Impaction
- Dislocation

Arthritis

Radiographic Hallmarks of OA

- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of RA

- soft tissue swelling
- periarticular osteopenia
- joint space loss – typically uniform
- erosions

Bone Tumour

Approach

- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 years
 - diagnosis usually requires a biopsy if primary not located
 - few benign tumours/lesions have potential for malignant transformation
 - MRI is good for tissue delineation and preoperative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
 - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

**Benign Lesions which may have****Aggressive Features**

- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

**Periosteal Reaction**

"Onion skinning": Ewing's sarcoma
 "Sunburst", "hair on end": osteosarcoma
 "Codman's triangle": osteosarcoma, Ewing's sarcoma, subperiosteal abscess

Lytic = decreased density
 Sclerotic = increased density

Considerations and Tumour Characteristics

- age – most common tumours by age group
 - <1 year of age: metastatic neuroblastoma
 - 1-20 years of age: Ewing's tumour in tubular bones
 - 10-30 years of age: osteosarcoma and Ewing's tumour in flat bones
 - >40 years of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
 - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
 - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
 - diaphysis: fibrous dysplasia, aneurysmal bone cysts, brown tumours, eosinophilic granuloma, Ewing's sarcoma
- margins/zones of transition
 - transition area from normal bone to area of lesion reflects aggressiveness of the lesion
 - well-defined lesion with narrow zone of transition (i.e. sharp cut-off between normal and abnormal) suggests a non-aggressive process
 - thin sclerotic margin is also suggestive of a non-aggressive process
 - an ill-defined lesion with a permeative pattern is suggestive of an aggressive lesion
- expansile
 - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
- cortex
 - intact cortex is more likely benign
 - destruction of cortex is more likely aggressive
- periosteal reaction
 - mature well-formed solid periosteal reaction: most likely a non-aggressive process
- matrix mineralization
 - chondroid (popcorn calcification) or osseous
- soft tissue
 - soft tissue mass: seen in aggressive tumours
- see Figure 20 and Table 13

Figure 20. Radiographic Appearance of Bone Remodelling and Destruction Processes

Table 13. Characteristics of Benign and Malignant Bone Lesions

Benign	Malignant
Single lesion	Multiple lesions (metastatic/multiple myeloma) (some syndromes have multiple benign lesions)
No bone pain	Bone pain
Sharp area of delineation	Poor delineation of lesion – wide zone of transition
Overlying cortex intact	Loss of overlying cortex/bony destruction
No or simple periosteal reaction	Periosteal reaction – aggressive
Sclerotic margins with sharp zone of transition	Wide zone of transition
No soft tissue mass	Soft tissue mass

Note: for specific bone tumours see [Orthopaedics, OR42](#)

Metastatic Bone Tumours

- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumours
 - metastasis can cause a lytic (decreased density) or a sclerotic (increased density) reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial work-up
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- for most common metastatic bone tumours, see [Orthopaedics](#), OR43

Table 14. Characteristic Bone Metastases of Common Cancers

Lytic	Sclerotic	Expansile	Peripheral
Breast	Prostate	Thyroid	Lung
Lung	Breast	Renal	Kidney
Thyroid	Lymphoma		Melanoma
Kidney	Lung		
Multiple myeloma	Treated tumours		

Infection

Osteomyelitis

- Tc99m, followed by indium-111 labeled white cell scan or gallium radioisotope scan is the best modality to establish the presence of bone infection
- plain film
 - visible 8-10 days after process has begun
 - osteomyelitic changes on plain film
 - ♦ soft tissue swelling that is deep and extends from the bone with loss of tissue planes (because fat becomes edematous)
 - ♦ local periosteal reaction
 - ♦ pockets of air (from anaerobes) may be seen in the tissues
 - ♦ metaphysis over the area of infection may appear mottled and nonhomogeneous with a classic “moth-eaten” appearance
 - ♦ cortical destruction

Bone Abscess

- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie's abscess
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone

Metabolic Bone Disease

Osteoporosis

- with increasing age, hormonal changes lead to bone resorption exceeding bone formation
- reduction in amount of normal bone; fewer and thinner trabeculae; diffuse process; affecting all bones
- dual x-ray absorptiometry (DEXA) – gold standard for measuring bone mineral density
 - T-score: the number of standard deviations from the young adult mean
 - ♦ used to diagnose osteoporosis and is a measure of current fracture risk
 - ♦ clinically most valuable
 - ♦ $-2.5 < T < -1$ = osteopenia
 - ♦ $T \leq -2.5$ = osteoporosis
 - Z-score: the number of standard deviations from the age-matched mean
 - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
- appearance on plain film
 - osteopenia: reduced bone density on plain films
 - ♦ may also be seen with osteomalacia, hyperparathyroidism, and disuse
 - compression of vertebral bodies
 - biconcave vertebral bodies (“codfish” vertebrae)
 - long bones have appearance of thinned cortex and increased medullary cavity
 - look for complications of osteoporosis
 - ♦ e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami

Diagnostic sensitivity of DEXA highest when BMD measured at lumbar spine and proximal femur.

Osteoporosis
Reduced amount of bone

OsteoMalacia
Normal amount of bone, but reduced Mineralization of normal osteoid

Osteomalacia/Rickets

- reduction in bone density due to seams of unmineralized osteoid
- initial radiological appearance of both osteoporosis and osteomalacia is osteopenia (coarse and poorly defined bone texture)
- “fuzzy”, ill-defined trabeculae
- softening and bowing of long bones
- Looser’s zones (pseudofracture)
 - characteristic radiological feature
 - fissures or clefts at right angles to long bones and extending through cortex
- DDx: osteomalacia, chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget’s, osteodystrophy, X-linked hypophosphatemia

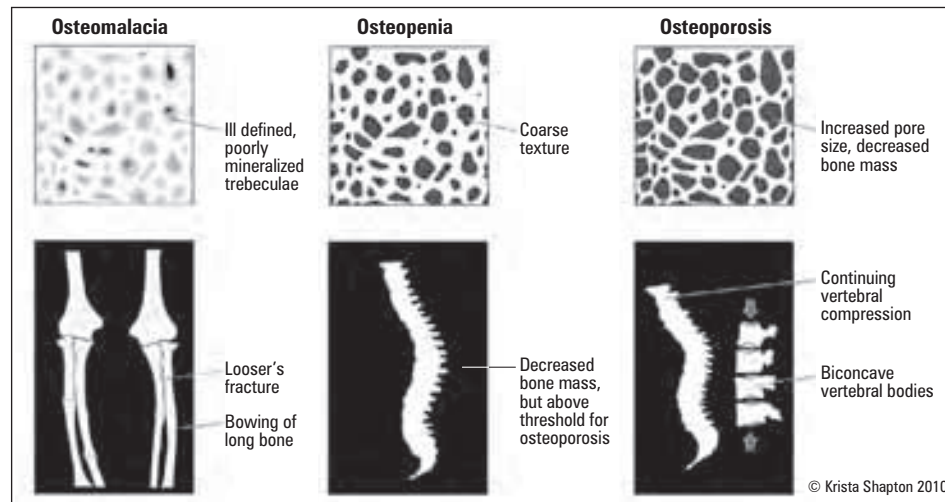

Figure 21. Osteomalacia, Osteopenia and Osteoporosis

Hyperparathyroidism

- most common cause is renal failure (secondary hyperparathyroidism)
- skeletal manifestations of chronic renal insufficiency
- chondrocalcinosis
 - calcifications of the soft tissues (including arteries and peri-articular soft tissue)
 - resorption of bone typically in hands (subperiosteal and at tufts), SI joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumours)
 - “rugger jersey spine”: band-like osteosclerosis at superior/inferior margins of vertebral bodies
- see [Endocrinology](#), E39

Paget’s Disease

- abnormal remodeling of bone – especially skull, spine, pelvis
- may involve single or multiple bones
- 3 phases: 1st lytic, 2nd mixed (lytic/sclerotic), 3rd sclerotic
- features
 - coarsening of the trabeculae with bone expansion
 - bone softening/bowing
 - bone scan will reveal high activity, especially at bone ends
 - thickened cortex
- complications
 - pathological fractures
 - cardiac failure
 - early OA
 - nerve entrapment in base of skull
 - malignant degeneration

Nuclear Medicine

Thyroid

Radioactive Iodine Uptake (see [Endocrinology](#), E20)

- index of thyroid function (trapping and organification of iodine)
- radioactive I-131 or I-123 given PO to fasting patient
 - measure percentage of administered iodine taken up by thyroid
- increased RAIU: toxic multinodular goiter, toxic adenoma, Graves' disease
- decreased RAIU: subacute thyroiditis, late Hashimoto's disease, hormone suppression
- falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed)

Thyroid Imaging (Scintiscan)

- Tc99m pertechnetate IV or radioactive iodine
- provides functional anatomic detail
- hot (hyperfunctioning) lesions
 - adenoma, toxic multinodular goiter
 - usually benign, cancer very unlikely (less than 1%)
- cold (hypofunctioning) lesions
 - cancer must be considered until biopsy negative even though only 6-10% are cancerous
- isointense lesions
 - cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue
 - if cyst suspected, correlate with U/S
- serum thyroglobulin to detect recurrent thyroid cancer post-treatment

Radioiodine Ablation

- I-131 for Graves' disease, multinodular goiter, thyroid cancer

Respiratory

V/Q Scan

- examine areas of lung in which ventilation and perfusion do not match
- ventilation scan
 - patient breathes radioactive gas through a closed system, filling alveoli proportionally to ventilation
 - ventilation scan defects indicate: airway obstruction, chronic lung disease, bronchospasm, tumour mass obstruction
- perfusion scan
 - radiotracer injected IV → trapped in pulmonary capillaries (1 in 1500 arterioles occluded) according to blood flow
 - gives a map of pulmonary circulation
 - relatively contraindicated in severe pulmonary HTN and right-to-left shunt
- with PE
 - areas of lung are well ventilated but not perfused (unmatched defect)
 - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
 - reported as high probability, intermediate, low, very low, or normal
 - V/Q scans for PE have been largely replaced by CT scan with contrast (see [Respirology](#), R18)

V/Q Scan

For PE investigation: normal scan makes PE unlikely.
Probability of PE: high 80-100%, intermediate 20-80%, low <20%.

Ventilation Scan Defects indicate:

airway obstruction, chronic lung disease, bronchospasm, tumour mass obstruction.

Perfusion Scan Defects indicate:

reduced blood flow due to PE, COPD, asthma, bronchogenic carcinoma, inflammatory lung diseases (pneumonia, sarcoidosis), mediastinitis, mucous plug, vasculitis.

Cardiac

Myocardial Perfusion Scanning

- for investigation of angina, atypical chest pain, coronary artery disease (CAD), and follow-up post-bypass
- thallium-201 (a radioactive analogue of potassium), Tc99m MIBI, or Tc99m tetrofosmin
- injected at peak exercise (physical stress) or after persantine challenge (vasodilator) and again later at rest
- persistent defect (at rest and stress) suggests infarction; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- see [Cardiology and Cardiovascular Surgery](#), C10 for more details

Active uptake of radiolabel by myocardium is proportional to regional blood flow.

Persistent defect (at rest and stress) suggests infarction; reversible defect (only during stress) suggests ischemia.

MUGA Scan can be used to study the function of the heart at a particular stage of contraction. Superior to ECHO only in its reproducibility in EF measurement (precise).

Radionuclide Ventriculography

- Tc99m attached to red blood cells
- first pass through right ventricle → pulmonary circulation → left ventricle; provides information about RV function
- cardiac MUGA scan (Multiple Gated acquisition scan) sums multiple cardiac cycles
 - evaluation of LV function
 - images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
 - MUGA scan can be used to study the function of the heart at a particular stage of contraction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion

Technetium pyrophosphate concentrates in bone and necrotic tissue.

Pyrophosphate Scintigraphy

- technetium pyrophosphate concentrates in bone and necrotic tissue
- used to detect infarcted tissue 1-5 days post-MI when ECG and enzyme results are equivocal or unreliable
- sensitivity and specificity about 90% for transmural infarct

Bone

Bone Scan

- isotopes
 - technetium Tc99m
 - ♦ triphasic bone scan: flow → blood pool → delayed bone images
 - ♦ uptake can distinguish bone vs. soft tissue infection and septic arthritis vs. osteomyelitis vs. peripheral cellulitis
 - ♦ acute osteomyelitis: increased activity in flow, blood pool, and delayed bone images; usually does not cross joint
 - ♦ septic arthritis and cellulitis: increased activity in blood pool and normal or slightly increased activity in delayed images; may cross joint
 - indium-111 WBC: tracks the active migration of the WBC, more specific for infection
 - gallium-67 citrate: may see uptake in some tumours, also more specific for infection
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- differential diagnosis of positive bone scan:
 - bone metastases from breast, prostate, lung, thyroid
 - primary bone tumour
 - arthritis
 - fracture
 - infection
 - anemia
 - Paget's disease
- multiple myeloma: typically normal or cold (false negative); need a skeletal survey
- superscan: good visualization of bone, but not kidneys, due to diffuse metastases or metabolic causes (renal osteodystrophy)

Indications for a Bone Scan

- Bone pain of unknown origin
- AVN
- Suspected malignancy
- Staging malignancy (cancer of breast, prostate, kidney, thyroid or lung)
- Follow up after treatment
- Detection and follow up of primary bone disease
- Assessment of skeletal trauma
- Detection of soft tissue calcification
- Renal failure

Abdomen

HIDA (Hepatobiliary IminoDiacetic Acid) Scan

- IV injection of radiotracer (HIDA) which is bound to protein, taken up, and excreted by hepatocytes into biliary system
- can be performed in non-fasting state but prefer NPO after midnight
- gallbladder visualized when cystic duct is patent, usually seen by 30 min to 1 hour
- if gallbladder is not visualized, suspect obstructed cystic duct (acute or chronic cholecystitis)
- acute cholecystitis: no visualization of gallbladder at 4-hours or after administration of morphine at 30 minutes
- chronic cholecystitis: no visualization of gallbladder at 1-hour but seen at 4-hours or after morphine administration
- differential diagnosis of obstructed cystic duct: acute cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 hours or more than 24 hours
- filling of gallbladder rules out cholecystitis (<1% probability)
- assess bile leaks post-operatively

RBC Scan

- IV injection of radiotracer with sequential images of the abdomen (Tc99m labeled RBCs)
- GI bleed
 - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image
 - if bleeding acutely at >0.5 mL/min, use angiography (more specific)
 - RBC scan is more sensitive for lower GI bleed
- liver lesion evaluation
 - hemangioma has characteristic appearance: cold early, fills in later

Renal Scan

- see *Genitourinary System*, DM15

Inflammation and Infection

- gallium-67 citrate, indium-111, or Tc99m labeled WBCs
- gallium accumulates in skeleton, lacrimal glands, nasopharynx, normal liver, spleen, bone marrow, sites of inflammation, some neoplasms (lymphomas)
- labeled WBCs accumulate in normal spleen, liver, bone marrow, sites of inflammation and infection (abscess, sarcoid, osteomyelitis)

Brain

- SPECT Tc99m-HMPAO or Tc99m-ECD imaging assesses cerebral blood flow, taken up in cortical and subcortical grey matter; used for CVA, vasculitis, dementia
- PET imaging assesses metabolic activity by using 18-FDG
- CSF imaging, intrathecal administration of 111-In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from other causes of hydrocephalus

Interventional Radiology

Vascular Procedures

Angiography

- injection of contrast material through a catheter placed directly into an artery (or vein) to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a “flush” or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- **indications:** diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (EVAR, thrombolysis, stenting and angioplasties)
- **complications:** puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- significant complications occur in $<5\%$ of patients
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CT angiography and MR angiography)
- see *Neuroradiology*, DM17 and *Angiography of GI Tract*, DM15

Percutaneous Transluminal Angioplasty (PTA) and Stents

- introduction and inflation of a balloon into a stenosed vessel to restore distal blood supply
- common alternative to surgical bypass grafting with five year patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long term results by keeping the vessel wall patent after PTA
- stents are also used for angioplasty failure or complications
- covered stents (a.k.a. stent grafts) may provide an alternative treatment option for aneurysms and AV fistulas
- **complications:** similar to angiography, but also includes vessel rupture

Thrombolytic Therapy

- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- **indications:** treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
- **complications:** bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

**Contraindications to Intravascular Contrast Media**

- Anaphylactic reaction
- Multiple myeloma
- Dehydration
- Diabetes

Relative Contraindications

- Renal failure
- Severe heart failure

Thrombolytic Therapy for Pulmonary Embolism
Cochrane Database of Systematic Reviews 2009, Issue 3

Study: Systematic review of randomized controlled trials comparing thrombolytic therapy with placebo, heparin, or surgical intervention.

Patients: 679 patients with acute PE.

Intervention: Thrombolytics vs. heparin or placebo.

Outcome: Death rate, recurrence of PE, major and minor hemorrhagic events.

Results: Non-significant difference between thrombolytics and heparin or placebo in all measured outcomes. Rt-PA and heparin together reduced need for treatment for in-hospital events. Thrombolytics improved hemodynamic outcome, lung VQ scans, pulmonary angio assessment and echocardiograms greater than heparin. Need for further double-blinded RCTs.

Advanced ischemia patients should receive surgery rather than thrombolysis.

Indications for Central Venous Access
FAT CAB
 Fluids
 Antibiotics
 TPN
 Chemotherapy
 Administration of blood
 Blood sampling

Figure 22. Retrievable IVC Filter

Figure 23. Femoral Arteriogram
 – showing distal occlusion of
 superficial femoral artery

ERCP is the primary modality for distal
 common bile duct obstructions.

Embolization

- injection of occluding material into vessels
- permanent agents: coils, balloons, glue
- temporary: gel foam, autologous blood clots
- **indications:** management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of AVM, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
- **complications**
 - post embolization syndrome (pain, fever, leukocytosis)
 - unintentional embolization of a non-target organ with resultant ischemia

Inferior Vena Cava Filter

- insertion of metallic “umbrellas” to mechanically trap emboli and prevent PE
- may be temporary (retrievable) or permanent
- inserted via femoral vein, jugular vein, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- **indications:** contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

Central Venous Access

- variety of devices available
 - peripherally inserted central catheter (PICC), external tunneled catheter (Hickmann or dialysis catheters), subcutaneous port (Portacath®)
- **indications:** chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- **complications:** venous thrombosis and central venous stenosis, infection including sepsis, pneumothorax

Nonvascular Interventions

Percutaneous Biopsy

- replaces open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy or CT guidance
- **complications**
 - false negative biopsies due to sampling error or tissue necrosis
 - pneumothorax in 30% of lung biopsies, chest tube required in approximately 5%
 - pancreatic biopsies are associated with risk of inducing acute pancreatitis
 - transjugular liver biopsies can be performed to minimize bleeding complications in patients with uncorrectable coagulopathies or ascites

Abscess Drainage

- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- **complications**
 - hemorrhage
 - injury to intervening structures (e.g. bowel)
 - bacteremia, sepsis

Percutaneous Biliary Drainage (PBD)/Cholecystostomy

- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- **indications**
 - cholecystostomy: acute cholecystitis
 - percutaneous biliary drainage: biliary obstruction secondary to stone or tumour, cholangitis
- **complications**
 - acute: sepsis, hemorrhage
 - long-term: tumour overgrowth and stent occlusion

Percutaneous Nephrostomy

- placement of catheter into renal collecting system
- **indications:** hydronephrosis (urinary obstruction as a result of a stone or tumour), pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- **complications:** bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy

- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- **indications**
 - feeding: inability to eat (most commonly CNS lesion, e.g. stroke) or esophageal obstruction
 - decompression: gastric outlet obstruction
- **complications:** gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency (RF) Ablation

- U/S or CT guided probe is inserted into tumour, RF energy delivered through probe causes heat deposition and tissue destruction
- **indications:** hepatic tumours (hepatocellular carcinoma and metastases), renal tumours
- **complications:** destruction of neighbouring tissues and structures, bleeding

Women's Imaging

Modalities

MAMMOGRAPHY**Description**

- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities

Indications

- screening
 - begin screening from age 40 or 50 at one to two-year intervals
 - if over the age of 70, continue screening mammography if in good general health
 - not routinely recommended if under the age of 40 unless strong family history
 - begin 5-10 years younger than the first degree relative who developed breast cancer
- diagnostic
 - signs and symptoms suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
 - women with abnormal screening mammograms
 - follow-up of women with previous breast cancer
 - suspected complications of breast implants

BREAST MRI**Description**

- breast MRI should be used only after mammography and ultrasound investigation
- sensitive for detecting invasive breast cancer (95-100%) but not specific (37-97%)
- use as a screening modality has been limited to high risk patients

Indications

- evaluation of diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
- post-surgical resection of breast cancer
- known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer
- untested first-degree relative of a carrier of such a gene mutation
- family history consistent with a hereditary breast cancer syndrome and estimated personal lifetime cancer risk >25%
- high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
- radiation therapy to chest (before age 30)
- NOTE: MRI should not be used to screen the general population or to differentiate between benign and malignant lesions

ULTRASOUND

Definition

- ultrasound can determine if a mass is cystic or solid and is commonly used during biopsy

Indications

- identification and characterization of palpable abnormalities
- evaluation of ambiguous mammographic findings in the determination of cystic versus solid characteristics
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- guidance for interventional procedures
- breast sonography is the initial imaging technique to evaluate palpable masses in women under 30 and in lactating and pregnant women

BREAST INTERVENTIONAL PROCEDURES

Description

- breast interventional procedures include FNA biopsy, core needle biopsy, abscess drainage, and cyst aspiration

Indications

- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) or confirm diagnosis of a probably benign mass (BI-RADS® Category 3)
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical ultrasound-guided localization of a lesion

Breast Imaging Reporting

Breast Imaging Reporting and Data System (BI-RADS®)

- a widely accepted standardized reporting system for breast imaging published by the American College of Radiology

Format of Report

1. indication for exam
2. breast composition
3. finding(s)
4. comparison to previous studies (if available)
5. overall assessment

Breast Composition

- dense breast tissue makes it difficult to separate normal gland tissue from tumours
- BI-RAD system grades composition of breast tissue
 - almost entirely fatty: mammography very effective, sensitive to even small tumours
 - scattered fibroglandular tissue: minor decrease in sensitivity
 - heterogeneously dense tissue: moderate decrease in sensitivity
 - extremely dense tissue: marked decrease in sensitivity

Overall Assessment Categories

- Category 0 – need additional imaging evaluation: technically unsatisfactory scan or when more information is needed to interpret the scan (e.g. prior imaging, correlation with history)
- Category 1 – negative: nothing to comment on; breasts are symmetrical, no masses, architectural disturbances, or suspicious calcifications are present; routine follow-up advised
- Category 2 – benign finding: negative mammogram with benign findings (e.g. calcifications, lipoma, lymph nodes)
- Category 3 – probably benign finding: short interval follow-up suggested
- Category 4 – suspicious abnormality: biopsy should be considered
 - Category 4A may be used for a finding needing intervention but with a low suspicion for malignancy
 - Category 4B includes lesions with an intermediate suspicion of malignancy and warrants close radiologic and pathologic correlation
 - Category 4C includes findings of moderate concern, but not classic (as in Category 5) for malignancy; malignant result in this category is expected
- Category 5 – highly suggestive of malignancy: appropriate action should be taken
- Category 6 – known biopsy-proven malignancy: appropriate action should be taken; a cancer diagnosis that has been established by histology is imaged and corresponds to the previously biopsied lesion

Breast Findings

Breast Masses

- definition: a space occupying lesion seen in two different projections; if seen in only a single projection it should be called a "density" until its three-dimensionality is confirmed
 - when a density is seen on one view, additional views must be done to confirm or exclude the presence of a mass; this may mean asking the patient to return
- shape: oval, round, or lobular suggests benign; irregular is more concerning for malignancy
- margin: indistinct, microlobulated, or frankly speculated (radiating lines) margins suggest infiltration; circumscribed, well-defined margins are reassuring; may require focal magnification mammogram to fully characterize margin
- density: higher density than surrounding tissue is suspicious for malignancy; radiolucent lesions are fat-containing and may be an oil cyst, lipoma, galactocele, hamartoma or fibrolipoma

Architectural Distortion

- definition: the normal architecture is distorted with no definite mass visible; this includes spiculations radiating from a point, and focal retraction or distortion of the edge of the parenchyma; may be concerning for malignancy or occur with healing after injury (including previous biopsy)
- spiculations (lines radiating from the centre)
- retraction (puckering) of normal connective tissues lines

Calcifications

- size: benign calcifications are usually larger than calcifications associated with malignancy
- shape: benign lesions are often round with smooth margins and are much more easily seen; hazy "flake" shaped lesions are indeterminate; thin, irregular, and branched suggest malignancy
- distribution: regional, scattered, and diffuse calcifications suggest benign; grouped, linear or segmental calcifications are suspicious for malignancy
- typically benign forms:
 - skin calcifications: lucent-centred and benign
 - vascular calcifications: parallel paired tracks or linear tubular calcifications clearly associated with calcification of small arteries
 - coarse or popcorn-like calcifications: classic rounded groups of coarse calcifications develop in an involuting fibroadenoma
 - large rod-shaped calcifications: benign calcifications forming continuous rods that may occasionally branch; usually more than 1 mm in diameter, may have lucent centre if calcium surrounds rather than fills an enlarged duct; found in secretory disease, plasma cell mastitis, and duct ectasia
 - round calcifications: usually considered benign and when small (under 1 mm), the term punctate may be used; smooth, dense, and round
 - spherical or lucent-centred calcifications: benign calcifications that range from under 1 mm to over a centimeter; smooth surfaces, round or oval, tend to have a lucent centre; arise from areas of fat necrosis, calcified duct debris, and occasionally fibroadenoma

Intermediate Concern Calcifications

- amorphous or indistinct calcifications: round or "flake" shaped calcifications that are sufficiently small or hazy in appearance that a more specific morphologic classification cannot be determined; biopsy may be necessary

Calcifications of High Probability of Malignancy

- pleomorphic or heterogeneous calcifications (granular): usually more conspicuous than amorphous forms, but are neither characteristic of a benign calcification, nor typically malignant; irregular calcifications of varying size and shape, usually less than 0.5 mm in size
- fine and/or branching (casting) calcifications: thin, irregular calcifications that appear linear, but are discontinuous and under 0.5 mm in width; their appearance suggests filling of the lumen of a duct involved irregularly by breast cancer

Other Findings

- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetric density: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
 - if focal compression shows mass-like character, or if the area can be palpated, biopsy must be considered

Initial Patient Assessment/Management

1. Rapid Primary Survey (RPS)

Approach to the Critically Ill Patient

1. Rapid Primary Survey (RPS)
2. Resuscitation (often concurrent with RPS)
3. Detailed Secondary Survey
4. Definitive Care

Noisy breathing is obstructed breathing until proven otherwise.

Signs of Airway Obstruction

- Agitation, confusion, "universal choking sign"
- Respiratory distress
- Failure to speak, dysphonia
- Cyanosis

Medications that can be Delivered via ETT

NAVEL

- Naloxone (Narcan)
- Atropine
- Ventolin (Salbutamol)
- Epinephrine
- Lidocaine

Indications for Intubation

- Unable to protect airway (e.g. Glasgow Coma Scale (GCS) <8; airway trauma)
- Inadequate oxygenation with spontaneous respiration (O_2 saturation <90% with 100% O_2 or rising pCO_2)
- Profound shock
- Anticipatory: in trauma, overdose, congestive heart failure (CHF), asthma, chronic obstructive pulmonary disease (COPD) and smoke inhalation injury
- Anticipated transfer of critically ill patients

Added Equipment and Techniques in Intubation

- Bougie (used like a guidewire)
- Retrograde intubation (ETT threaded over a wire inserted through skin and out mouth)
- Lighted stylet (use light through skin to determine if ETT in correct place)
- Fiberoptic intubation – indirect vision using fiberoptic cable

- Airway maintenance with cervical spine (C-spine) control

- Breathing and ventilation

- Circulation (pulses, hemorrhage control)

- Disability (neurological status)

- Exposure (complete) and Environment (temperature control)

- Continually reassessed during secondary survey

IMPORTANT: always watch for signs of shock while doing primary survey (see Table 1)

A. AIRWAY

- first priority is to secure airway

- assume a cervical injury in every trauma patient and immobilize with collar

- assess ability to breathe and speak

- can change rapidly, therefore reassess frequently

Airway Management

- goals

- permit adequate oxygenation and ventilation

- facilitate ongoing patient management

- give drugs via endotracheal tube (ETT) if IV not available

- Note: start with basic management techniques before progressing to advanced (see below)

1. Basic Airway Management (Temporizing Measures)

- protect the C-spine

- head-tilt (if C-spine injury not suspected) or jaw thrust to open the airway

- sweep and suction to clear mouth of foreign material

2. Definitive Airway Management

- ETT intubation with inline stabilization of spine (Figure 1)

- orotracheal ± Rapid Sequence Intubation (RSI) preferred

- nasotracheal – may be better tolerated in conscious patient

- ♦ relatively contraindicated with basal skull fracture

- does not provide 100% protection against aspiration

- surgical airway (if unable to intubate using oral/nasal route and unable to ventilate)

- cricothyroidotomy

3. Rescue or Temporizing Measures

- nasopharyngeal airway

- oropharyngeal airway (not if gag reflex present)

- "rescue" airway devices (e.g. laryngeal mask airway (LMA); Combitube®)

- transtracheal jet ventilation through cricothyroid membrane (last resort)

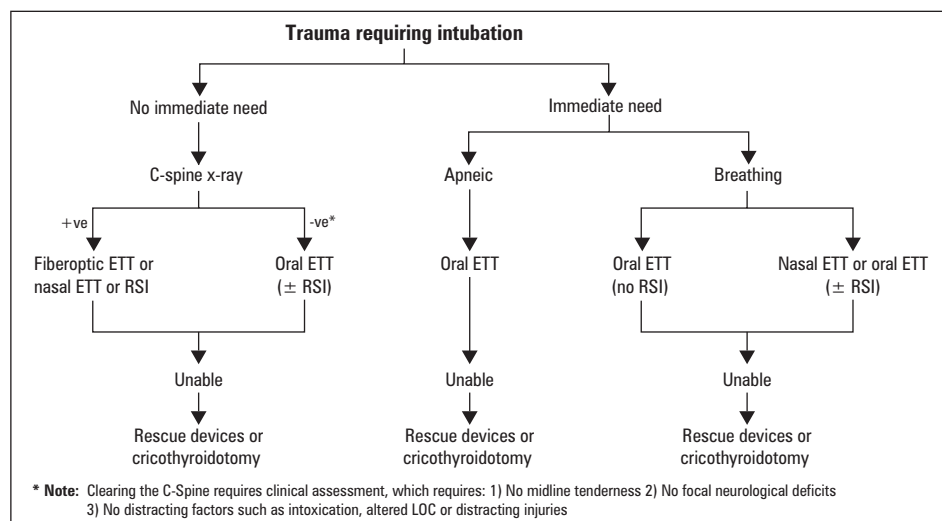

Figure 1. Approach to Endotracheal Intubation in an Injured Patient

ETT – endotracheal tube intubation; RSI – rapid sequence intubation

B. BREATHING

- **Look**
 - mental status (anxiety, agitation, decreased LOC), colour, chest movement (bilateral vs. asymmetrical), respiratory rate/effort, nasal flaring
- **Listen**
 - sounds of obstruction (e.g. stridor), breath sounds, symmetry of air entry, air escaping
- **Feel**
 - flow of air, tracheal shift, chest wall for crepitus, flail segments, sucking chest wounds, subcutaneous emphysema

Breathing Assessment

- measurement of respiratory function: rate, pulse oximetry, arterial blood gas (ABG), A-a gradient

Management of Breathing

- nasal prongs → simple face mask → oxygen reservoir → CPAP/BiPAP
- Venturi mask: used to precisely control O₂ delivery
- Bag-Valve mask and CPAP to supplement ventilation

C. CIRCULATION

Definition of Shock

- inadequate organ and tissue perfusion with oxygenated blood (brain, kidney, extremities) (see Table 2)

Table 1. Major Types of Shock

Hypovolemic	Cardiogenic	Distributive (vasodilation)	Obstructive
Hemorrhage (external and internal)	Myocardial Ischemia	Septic	Cardiac tamponade
Severe burns	Arrhythmias	Anaphylactic	Tension pneumothorax
High output fistulas	Congestive Heart Failure	Neurogenic (spinal cord injury)	Pulmonary embolism
Dehydration (diarrhea, DKA)	Cardiomyopathies		Aortic stenosis
	Cardiac valve problems		Constrictive pericarditis

Clinical Evaluation

- early: tachypnea, tachycardia, narrow pulse pressure, reduced capillary refill, cool extremities and reduced central venous pressure (CVP)
- late: hypotension and altered mental status, reduced urine output

Table 2. Estimation of Degree of Hemorrhagic Shock

Class	I	II	III	IV
Blood Loss	<750 cc	750-1500 cc	1500-2000 cc	>2000 cc
% of blood volume	<15%	15-30%	30-40%	>40%
Pulse	<100	>100	>120	>140
Blood pressure	Normal	Normal	Decreased	Decreased
Respiratory rate	20	30	35	>45
Capillary refill	Normal	Decreased	Decreased	Decreased
Urinary output	30 cc/hr	20 cc/hr	10 cc/hr	None
Fluid replacement	Crystalloid	Crystalloid	Crystalloid + blood	Crystalloid + blood

Management of Hemorrhagic Shock

- secure airway and supply O₂
- **TREAT THE CAUSE OF THE SHOCK**
- control external bleeding
 - direct pressure
 - elevate extremities if no obvious unstable fracture
 - consider vascular pressure points (brachial, axillary, femoral)
 - do not remove impaled objects as they tamponade bleeding
 - tourniquet only as last resort
- prompt surgical consultation for active internal bleeding
- infusion of 1-2 L of NS/RL as rapidly as possible → 2 large bore (14 gauge) IVs wide open
- warm blood/IV fluids, especially for massive transfusions
- replace lost blood volume at ratio of 3:1 with crystalloid
- if inadequate response, consider ongoing blood loss (e.g. chest, abdomen, pelvis, extremities) → operative intervention required
- indications for blood transfusion
 - severe hypotension on arrival
 - shock persists following crystalloid infusion
 - rapid bleeding

Shock in a trauma patient is hemorrhagic until proven otherwise.

Causes of Shock

SHOCKED

Septic, Spinal/neurogenic, Hemorrhagic
 Obstructive (e.g. tension pneumothorax, cardiac tamponade, pulmonary embolism)
 Cardiogenic (e.g. blunt myocardial injury, arrhythmia, MI)
 anaphylactic
 Endocrine (e.g. Addison's, myxedema, coma)
 Drugs

Estimated Systolic Blood Pressure Based on Position of Most Distal Palpable Pulse

	sBP (mmHg)
Radial	>80
Femoral	>70
Carotid	>60

Hemorrhage Management

RED

Rest

Elevate the bleeding area above the level of the heart if possible
 Direct pressure on the bleeding site

Fluid Resuscitation

Give bolus until HR decreases, urine output picks up, and patient stabilizes
 Maintenance: 4-2-1 rule
 first 10kg: 4cc/kg/hr
 10-20kg: 2cc/kg/hr
 remaining weight: 1cc/kg/hr
 replace ongoing losses and deficits (assume 10% of body weight)

Since only 30% of infused isotonic crystalloids remains in intravascular space, you must give 3x estimated blood loss.

Initial Management of Any Patient in Shock

ABCs
IV fluids
Oxygen
Monitor (HR, BP, urine, mentation, O₂ sat.)
Control hemorrhage

Method of Assessing Level of Consciousness

AVPU

Alert
Responds to Verbal stimuli
Responds to Painful stimuli
Unresponsive

Unproven or Harmful Treatments for Hemorrhage Shock

- Trendelenburg position
- Steroids (used only in spinal cord injury)
- MAST garments
- Vasopressors

Vasopressin versus Norepinephrine Infusion in Patients with Septic Shock

NEJM 2008; 358:877-87

Study: Multicenter, randomized, double-blind trial
Patients: 778 patients with septic shock

Intervention: Low-dose vasopressin (0.01 to 0.03 U per minute) or norepinephrine (5 to 15 ug per minute) in addition to open-label vasopressors and a minimum of 5ug of norepinephrine.

Outcome: Mortality rate 28 days after start of infusions.

Results: No significant difference between the vasopressin and the norepinephrine groups at 28 days or 90 days. However, in patients with less severe septic shock, mortality rate was lower in the vasopressin group.

Foley Contraindications

- Blood at urethral meatus
- Scrotal hematoma
- High-riding prostate on DRE

NG Tube Contraindications

- Significant mid-face trauma
- Basal skull fracture

- transfusion options with packed red blood cells (pRBCs)
 - crossmatched if possible
 - type-specific (provided by most blood banks within 10 minutes)
 - ♦ preferred to O-negative un-crossmatched blood if both available
 - O-negative (children and women of child-bearing age)
 - O-positive if no time for cross-match (males/postmenopausal women)
 - anticipate complications with massive transfusions
 - consider replacement of other blood products (platelets, FFP) after 2-4 units pRBCs
- transfusion with fresh frozen plasma (FFP)
 - used for clinical evidence of impaired hemostasis
 - ongoing hemorrhage, PT >1.5x normal range

D. DISABILITY

- assess level of consciousness by AVPU method (see sidebox) or GCS

Glasgow Coma Scale (GCS)

- for use in trauma patients with decreased LOC; good indicator of severity of injury and neurosurgical prognosis
- may be used for metabolic coma, but less meaningful
- most useful if repeated and used for monitoring of trend
 - change in GCS with time is more relevant than the absolute number
 - patient with deteriorating GCS needs immediate attention
 - prognosis based on **best post-resuscitation** GCS
- reported as a 3 part score: Eyes + Verbal + Motor = Total (see Table 3)
- if patient intubated, GCS score reported out of 10 + T (T= tubed, i.e. no verbal component)

Table 3. Glasgow Coma Scale

Eyes Open		Best Verbal Response		Best Motor Response	
Spontaneously	4	Answers questions appropriately	5	Obeys commands	6
To voice	3	Confused, disoriented	4	Localizes to pain	5
To pain	2	Inappropriate words	3	Withdraws from pain	4
No response	1	Incomprehensible sounds	2	Decorticate (flexion)	3
		No verbal response	1	Decerebrate (extension)	2
				No response	1

13-15 = mild injury, 9-12 = moderate injury, ≤8 = severe injury

See Table 28 for modified GCS for infants and children

E. EXPOSURE/ENVIRONMENT

- undress patient completely and assess entire body for injury; logroll to examine back
- digital rectal exam
- keep patient warm with a blanket ± radiant heaters; avoid hypothermia
- warm IV fluids/blood
- keep providers safe (contamination, combative patient)

2. Resuscitation

- done simultaneously with primary survey
- attend to ABCs (see Table 4)
- manage life-threatening problems as they are identified
- vital signs q5-15 minutes
- ECG, BP and O₂ monitors
- Foley catheter and nasogastric (NG) tube if indicated
- tests and investigations: CBC, electrolytes, BUN, Cr, glucose, amylase, INR/PTT, β-hCG, toxicology screen, cross and type

Table 4. 2005 AHA CPR Guidelines

Step/Action	Adult: >8yrs	Child: 1-8 years	Infant: <1 year
Airway	Head tilt-chin lift		
Breaths	2 breaths at 1 second/breath		
Foreign-body airway obstruction	Abdominal thrust		Back slaps and chest thrusts
Compressions			
Compression landmarks	In the centre of the chest, between nipples		Just below nipple line
Compression method: push hard and fast and allow for complete recoil	2 Hands: Heel of 1 hand, second hand on top	2 Hands: Heel of 1 hand with second on top, or 1 Hand: Heel of 1 hand only	2 fingers
Compression depth	1 ½ to 2 inches	About ⅓ to ½ the depth of the chest	
Compression rate	100/min		
Compression-ventilation ratio	30 compressions to 2 ventilations		
Compression-only CPR	Hands-only CPR is preferred if the bystander is not trained or does not feel confident in their ability to provide conventional CPR or if the bystander is trained but chooses to use compressions-only		
Defibrillation	Immediate defibrillation for all rescuers responding to a sudden witnessed collapse. Compression (5cycles/2min) before AED is considered if EMS arrival is > 4-5 minutes after the call		No defibrillation

3. Detailed Secondary Survey

- done after rapid primary survey problems have been addressed
- identifies major injuries or areas of concern
- full physical exam and x-rays (C-spine, chest, pelvis – required in blunt trauma, consider T-spine and L-spine)

HISTORY

- “SAMPLE”: Signs and Symptoms, Allergies, Medications, Past medical history, Last meal, Events related to injury

PHYSICAL EXAMINATION

Head and Neck

- pupils
 - assess equality, size, symmetry, reactivity to light
 - ♦ inequality/sluggish suggests local eye problem or lateralizing CNS lesion
 - ♦ relative afferent pupillary defect (swinging light test) – optic nerve damage
 - ♦ extraocular movements and nystagmus
 - ♦ fundoscopy (papilledema, hemorrhages)
 - reactivity/level of consciousness (LOC)
 - reactive pupils + decreased LOC → metabolic or structural cause
 - non-reactive pupils + decreased LOC → structural cause (especially if asymmetric)
- palpation of facial bones, scalp

Chest

- inspect for midline trachea, flail segment: ≥2 rib fractures in ≥2 places; if present look for associated hemothorax, pneumothorax, and contusions
- auscultate lung fields
- palpate for subcutaneous emphysema

Abdomen

- assess for peritonitis, abdominal distention, and evidence of intra-abdominal bleeding
- FAST (Focused Abdominal Sonogram in Trauma), diagnostic peritoneal lavage (DPL) or CT
- rectal exam for GI bleed, high riding prostate and anal tone (best to do during the log roll)
- bimanual exam in females as appropriate

Musculoskeletal (MSK)

- examine all extremities for swelling, deformity, contusion, tenderness, range of motion
- check for pulses and sensation in all injured limbs
- log roll and palpate thoracic and lumbar spines
- palpate iliac crests and pubic symphysis, pelvic stability (lateral, AP, vertical)

Unilateral, Dilated, Non-reactive Pupil, Think:
Focal mass lesion
Epidural hematoma
Subdural hematoma

Non-contrast head CT is the best imaging modality for intracerebral injury.

Signs of Increased Intracranial Pressure (ICP)

- Deteriorating LOC (hallmark)
- Deteriorating respiratory pattern
- Cushing reflex (high BP, low heart rate, irregular respirations)
- Lateralizing CNS signs (e.g. cranial nerve palsies, hemiparesis)
- Seizures
- Papilledema (occurs late)
- N/V and H/A

Neurological

- GCS
- full cranial nerve exam
- alterations of rate and rhythm of breathing are signs of structural or metabolic abnormalities
 - progressive deterioration of breathing pattern implies a failing CNS
- assess spinal cord integrity
 - conscious patient: assess distal sensation and motor
 - unconscious patient: response to painful or noxious stimulus applied to extremities

4. Definitive Care

- continue therapy
- continue patient evaluations and special investigations
- specialty consultations including OR as needed
- disposition: home, admission, or transfer to another setting (e.g. OR, ICU)

Ethical Considerations**Consent to Treatment: Adults**

- Emergency Rule: consent is not needed when patient is at imminent risk from a serious injury (e.g. severe suffering, loss of limb, vital organ or life) AND obtaining consent is either: a) not possible (e.g. patient is comatose); OR b) would increase risk to the patient (e.g. time delay)
 - assumes that most people would want to be saved in an emergency
- any capable and informed patient can refuse treatment, even if it is life-saving
 - consider: is the patient truly capable? Does pain, stress, or psychological distress impair their judgment?
- exceptions to the Emergency Rule: treatment cannot be initiated if
 - a competent patient has previously refused the same or similar treatment and there is no evidence to suggest the patient's wishes have changed
 - an advance directive is available – e.g. do not resuscitate (DNR) order
- refusal of help in a suicide situation is not an exception; care must be given
- if in doubt, initiate treatment
 - care can be withdrawn if appropriate at a later time or if wishes clarified by family

Consent to Treatment: Children

- treat immediately if patient is at imminent risk
- parents/guardians have the right to make treatment decisions
- if parents refuse treatment that is life-saving or will potentially alter the child's quality of life, Children's Aid Society (CAS) must be contacted – consent of CAS is needed to treat

Other Issues of Consent

- need consent for HIV testing, as well as for administration of blood products

Duty to Report

- law may vary depending on province and/or state
 - gunshot wounds, potential drunken drivers, suspected child abuse, various communicable diseases
 - medical unsuitability to drive

Traumatology

- epidemiology
 - leading cause of death in patients <45 yrs
 - 4th highest cause of death in North America
 - causes more deaths in children/adolescents than all diseases combined
- trimodal distribution of death
 - minutes: lethal injuries, death usually at the scene
 - early: death within 4-6 hours – “golden hour” (but decreased mortality with trauma care)
 - days-weeks: death from multiple organ dysfunction, sepsis, etc.
- injuries generally fall into two categories
 - blunt (most common): motor vehicle collision (MVC), pedestrian-automobile impact, motorcycle collision, fall, assault, sports
 - penetrating (increasing in incidence): gunshot wound, stabbing, impalement

Considerations for Traumatic Injury

- important to know the mechanism of injury in order to anticipate traumatic injuries
- always look for an underlying cause (alcohol, medications, illicit substances, seizure, suicide attempt, medical problem)
- always inquire about head injury, loss of consciousness, amnesia, vomiting, headache and seizure activity

**Jehovah's Witnesses**

- Capable adults have the right to refuse medical treatment
- May refuse whole blood, pRBCs, platelets and plasma even if life-saving
- Should be questioned directly about the use of albumin, immunoglobulins, hemophilic preparations
- Do not allow autologous transfusion unless there is uninterrupted extra corporeal circulation
- Usually ask for the highest possible quality of care without the use of the above interventions (e.g. crystalloids for volume expansion, attempts at bloodless surgery)
- Patient will generally sign hospital forms releasing medical staff from liability
- Most legal cases involve children of Jehovah's Witnesses; if life-saving treatment is refused contacted CAS

**High Risk Injuries**

- MVC at high speed, resulting in ejection from vehicle
- Motorcycle collisions
- Vehicle vs. pedestrian crashes
- Fall from height > 12 ft (3.6 m)

Motor Vehicle Collision (MVC)

- vehicle(s) involved: weight, size, speed, amount of damage
- type of crash (to assess location of possible injuries)
 - lateral/T-bone and head-on: head, cervical spine, thoracic, abdominal, pelvic and lower extremity
 - rear-end: hyper-extension of cervical spine (whiplash injury to neck)
 - roll over: energy dissipated, less likely severe injury if victim restrained by seatbelt, however still significant potential morbidity
- location of patient in vehicle
- use and type of seatbelt
 - lap belt: spine and abdominal injury
 - shoulder belt: look for major vessel injury
- ejection of patient from vehicle/entrapment of patient under vehicle
- airbag deployment
- use of helmet in motorcycle or bicycle collisions

Pedestrian-Automobile Impact

- high morbidity and mortality
- vehicle speed is an important factor
- site of impact on car
 - children tend to be run over
 - adults tend to be struck in lower legs, impacted again on car (truncal injury) and thrown to the ground (head injury)

Falls

- 1 storey = 12 feet = 3.6 m
- distance of fall: 50% mortality at 4 stories and 95% mortality at 7 stories
- position in which patient landed and type of surface
- assess for shock, lower extremity, spine and pelvic fractures

Gunshot Wounds (GSW)

- type of gun
 - handgun injuries: low or medium velocity, extent of injury may be limited to a small area
 - hunting and rifle injuries: high velocity, widespread injury
 - shot gun: widespread tissue destruction
- type of ammunition (e.g. hollow point bullets)
- range of shot
 - close range: massive tissue destruction, deposition of wadding into wound
- characterize route of entry, even or odd number of wounds and site of exit wound (if any)
 - GSW with hypotension: immediate transport to OR
 - hypotension indicates severe blood loss (>2 L blood loss in 70 kg patient is required to produce hypotension)

Stab Wounds

- route/direction of entry, length of blade
- type of penetration (stab, slash, impalement)
- victim recollection and witness reports are often inaccurate and may not correlate with depth/severity of wound
- if blade in-situ, DO NOT REMOVE – it may be tamponading bleeding vessel (to be removed in OR)

Vehicle vs. Pedestrian Crash
In adults look for triad of injuries (Waddle's triad):
1. Tibia-fibula or femur fracture
2. Truncal injury
3. Craniofacial injury

Cardiac box: sternal notch, nipples and xiphoid process; injuries inside this area should increase suspicion of cardiac injury.

Always completely expose and count the number of wounds.

Head Trauma

- see Neurosurgery, NS29
- 60% of trauma admissions have head injuries
- 60% of MVC-related deaths are due to head injury

Specific Injuries

- **fractures** (diagnosed by CT head, often not visible on x-ray)
 - A. skull fractures
 - vault fractures
 - ♦ linear, non-depressed
 - most common
 - typically occur over temporal bone, in area of middle meningeal artery (commonest cause of epidural hematoma)
 - ♦ depressed
 - open (associated overlying scalp laceration, torn dura) vs. closed
 - basal skull
 - ♦ typically occur through floor of anterior cranial fossa (longitudinal more common than transverse)
 - ♦ clinical diagnosis superior as poorly visualized on CT (Battle's sign, raccoon eyes, CSF rhinorrhea/otorrhea, hemotympanum)

Signs of Basal Skull Fracture
Battle's sign (bruised mastoid process)
Hemotympanum
Raccoon eyes (periorbital bruising)
CSF Rhinorrhea/Otorrhea

**Warning Signs of Severe Head Injury**

- GCS <8
- Deteriorating GCS
- Unequal pupils
- Lateralizing signs
- N.B.** Altered LOC is a hallmark of brain injury.

B. facial fractures (see Plastic Surgery, PL26)

- neuronal injury
 - beware of open fracture or sinus fractures (risk of infection)
 - unstable or displaced fractures (need semi-urgent plastics referral)
 - severe facial fractures may pose risk to airway from profuse bleeding

- **neuronal injury**

A. diffuse

- concussion
 - ♦ mild: temporary disturbance of neurological function, complete recovery
 - ♦ classical: temporary, reversible neurological disturbance, with temporary (<6 hrs) loss of consciousness, complete recovery
- diffuse axonal injury
 - ♦ mild: coma 6-24 hrs, possibly lasting deficit
 - ♦ moderate: coma >24hrs, little or no signs of brainstem dysfunction
 - ♦ severe: coma >24hrs, frequent signs of brainstem dysfunction

B. focal injuries

- contusions
- intracranial hemorrhage (epidural, subdural, intracerebral)

ASSESSMENT OF BRAIN INJURY

History

- pre-hospital status
- mechanism of injury

Physical Examination

- assume C-spine injury until ruled out
- vital signs
 - shock (not likely due to isolated brain injury, except in infants)
 - Cushing's response to increasing ICP (bradycardia, hypertension, irregular respirations)
- severity of injury determined by
 1. level of consciousness (LOC)
 - ♦ GCS ≤8 intubate, any change in score of 3 or more = serious injury
 2. pupils: size, anisocoria >1 mm (in patient with altered LOC), response to light
 3. lateralizing signs (motor/sensory)
 - ♦ may become more subtle with increasing severity of injury
- re-assess frequently

Investigations

- labs: CBC, electrolytes, coags, glucose, tox screen
- CT scan (non-contrast) to exclude intracranial mass lesions
- C-spine imaging, often with CT head and neck to exclude intracranial mass lesions

Management

- general
 - ABCs
 - ensure oxygen delivery to brain through intubation and prevent hypercarbia
 - maintain BP
 - treat other injuries, must treat hypotension, hypoxia (both contribute significantly to mortality)
- early neurosurgical consultation for acute and subsequent patient management
 - medical
 - ♦ seizure treatment/prophylaxis
 - benzodiazepines, phenytoin, phenobarbital
 - steroids are of no proven value
 - ♦ treat suspected raised ICP → consider if head injury with signs of increased ICP:
 - raise head of stretcher 20° if patient hemodynamically stable
 - intubate and hyperventilate (100% O₂) to a pCO₂ of 30-35 mmHg
 - mannitol 1g/kg infused as rapidly as possible
 - consider paralyzing meds if agitated/high airway pressures
 - maintenance of cerebral perfusion pressure is critical
 - surgical

Disposition

- neurosurgical ICU admission for severe head injuries (HI)
- in hemodynamically unstable patient with other injuries, prioritize most life-threatening injuries and maintain cerebral perfusion
- for minor head injury not requiring admission, provide 24-hour HI protocol to competent caregiver, follow-up with neurology as even seemingly minor HI may cause lasting deficits

Canadian CT Head Rule

The Lancet 2001; 357:9266;1391-1396

CT Head is only required for patients with minor head injuries with any one of the following:

High risk (for neurological intervention)

- GCS score <15 at 2 h after injury
- Suspected open or depressed skull fracture
- Any sign of basal skull fracture (hemotympanum, "raccoon" eyes, cerebrospinal fluid otorrhea/rhinorrhea, Battle's sign)
- Vomiting ≥2 episodes
- Age ≥65 years

Medium risk (for brain injury on CT)

- Amnesia after impact >30 min
- Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs)

Minor head injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.

Treatment of Increased ICP

- Elevate head of bed
- Mannitol
- Hyperventilate
- Paralyzing agents/sedating agents

See also Neurosurgery, NS6

Spine and Spinal Cord Trauma

- assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck or back
- spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 2)
- vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
- cord may be injured despite normal C-spine x-ray (SCIWARA = spinal cord injury without radiologic abnormality)
- injuries can include: complete/incomplete transection, cord edema, spinal shock

History

- mechanism of injury, previous deficits, SAMPLE
- neck pain, paralysis/weakness, paresthesia

Physical Exam

- ABCs
- abdo: ecchymosis, tenderness
- neuro: complete exam, including mental status
- spine: maintain neutral position, palpate C-spine for tenderness, step-off; log-roll, then palpate thoracic and lumbar spine; assess rectal tone
- extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations

- labs: CBC, electrolytes, creatinine, glucose, coags, cross and type, tox screen
- imaging
 - full C-spine x-ray series for trauma (AP, lateral, odontoid)
- thoracolumbar x-rays
 - AP and lateral views
 - indications:
 - ♦ patients with C-spine injury
 - ♦ unconscious patients (with appropriate mechanism of injury)
 - ♦ patients with neurological symptoms or findings
 - ♦ patients with deformities that are palpable when patient log-rolled
 - ♦ patients with back pain
 - ♦ patients with bilateral calcaneal fractures (due to fall from height)
 - concurrent burst fractures of the lumbar or thoracic spine in 10% (T11-L2)
 - consider CT (for subtle bony injuries), MRI (for soft tissue injuries) if appropriate

Collar Everyone with at Least One of the Following Criteria

- Midline tenderness
- Neurological symptoms or signs
- Significant distracting injuries
- Head injury
- Intoxication
- Dangerous mechanism
- History of altered LOC

Note: Patients with penetrating trauma (especially gunshot and knife wounds) can also have spinal cord injury.

Of the investigations, the lateral C-spine x-ray is the single most important film. 95% of radiologically visible abnormalities are found on this film.

Cauda Equina Syndrome can occur with any spinal cord injury below T10 vertebrae. Look for incontinence, anterior thigh pain, quadriceps weakness, abnormal sacral sensation, decreased rectal tone and variable reflexes.

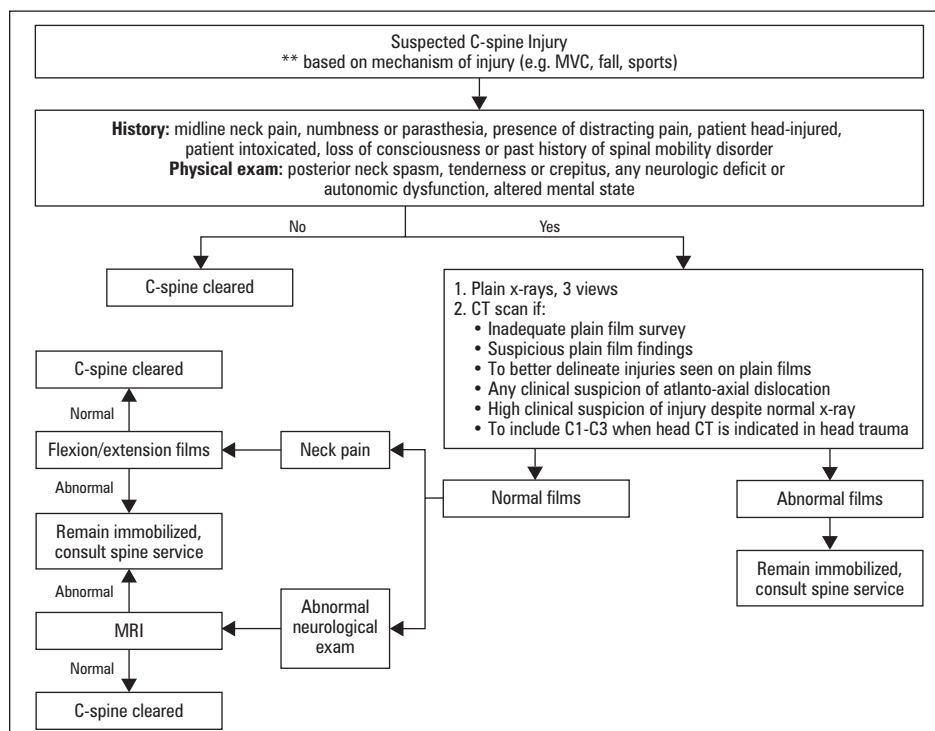

Figure 2. Approach to Clearing the C-spine

The Canadian C-spine Rule versus the NEXUS Low-risk Criteria in Patients with Trauma

NEJM 2003; 349(26):2510-8.

Purpose: To compare the clinical performance of the Canadian C-Spine Rule (CCR) and the National Emergency X-Radiography Utilization Study (NEXUS) Low-Risk Criteria (NLC).

Study: Trauma patients (n=8283) in stable condition were prospectively evaluated by both the CCR and NLC by 394 physicians before radiography. 2% of these patients had a C-spine injury.

Results: Compared to the NLC, the CCR was more sensitive (99.4 vs. 90.7%) and more specific (45.1 vs. 36.8%) after exclusion of indeterminate cases. The number of missed patients would be 1 for the CCR and 16 for the NLC. The range of motion was not evaluated in some CCR cases likely because physicians were not comfortable with the procedure and this may slightly lower the sensitivity or specificity of the CCR in practice.

Summary: The CCR is superior to the NLC in alert and stable patients with trauma. The use of the CCR can result in lower radiography rates.

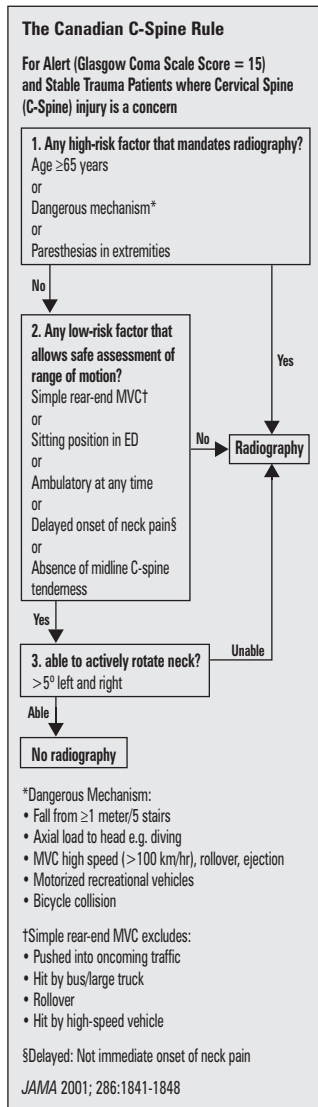

Figure 3. Lines of Contour on a Lateral C-Spine X-Ray

Can Clear C-spine if:

- no posterior midline cervical tenderness
- no evidence of intoxication
- oriented to person, place, time and event
- no focal neurological deficits
- no painful distracting injuries (e.g. long bone #)

Management of Cord Injury

- immobilize
- evaluate ABCs
- treat shock (maintain sBP >100 mmHg)
- insert NG and Foley catheter
- high dose steroids: methylprednisolone 30 mg/kg bolus, then 5.4 mg/kg/hr drip, start within 6-8 hrs of injury (controversial and recently has less support)
- complete imaging of spine and consult spine service if available
- continually reassess high cord injuries as edema can travel up cord
- if cervical cord lesion, watch for respiratory insufficiency
 - low cervical transection (C5-T1) produces abdominal breathing (phrenic innervation of diaphragm still intact)
 - high cervical cord injury (above C4) may require intubation and ventilation
- beware of hypotension (neurogenic shock)
 - treatment: warm blanket, Trendelenberg position (occasionally), volume infusion, consider vasopressors

Approach to C-Spine X-Rays

- 3-view C-spine series is the screening modality of choice
 1. lateral C1-T1 \pm swimmer's view (Figure 3, see Table 5 for interpretation)
 - ♦ lateral view is best, identifies 90-95% of injuries
 2. odontoid view (open mouth or oblique submental view) (see Figure 4)
 - ♦ examine the dens for fractures
 - beware of artifact (horizontal or vertical) caused by the radiological shadow of the teeth overlying the dens
 - if unable to rule out fracture, repeat view or consider CT or plain film tomography
 - ♦ examine lateral aspects of C1 and spacing relative to C2
 3. AP view
 - ♦ alignment of spinous processes in the midline
 - ♦ spacing of spinous processes should be equal
 - ♦ check vertebral bodies and facet dislocations

Supine Oblique Views

- rarely used
- better visualization of posterior element fractures (lamina, pedicle, facet joint)
- good to assess patency of neural foramina
- can be used to visualize the C7-T1 junction

Table 5. Interpretation of Lateral View: The ABCS

A Adequacy and Alignment	<ul style="list-style-type: none"> • Must see C1 to C7-T1 junction; if not, downward traction of shoulders, swimmer's view, bilateral supine obliques, or CT scan needed • Lines of contour – in children <8 years of age: can see physiologic subluxation of C2 on C3, and C3 on C4, but the spinolaminar line is maintained • Fanning of spinous processes – suggests posterior ligamentous disruption • Widening of facet joints • Check atlanto-occipital joint: <ul style="list-style-type: none"> ▪ Line extending inferiorly from clivus should transect odontoid ▪ Atlanto-axial articulation – widening of predental space (normal: <3 mm in adults, <5 mm in children) indicates injury of C1 or C2
B Bones	<ul style="list-style-type: none"> • Height, width and shape of each vertebral body • Pedicles, facets, and laminae should appear as one – doubling suggests rotation
C Cartilage	<ul style="list-style-type: none"> • Intervertebral disc spaces – wedging anteriorly or posteriorly suggests vertebral compression
S Soft Tissues	<ul style="list-style-type: none"> • Widening of retropharyngeal (normal: <7 mm at C1-4, may be wide in children <2 yrs on expiration) or retrotracheal spaces (normal: <22 mm at C6-T1, <14 mm in children <5 yrs)

Sequelae of C-spine Fractures

- decreased descending sympathetic tone (neurogenic/spinal shock) responsible for most sequelae
- autonomic dysreflexia: in patients with spinal cord injuries at or above the T6 level
 - common signs and symptoms: pounding headache, nasal congestion, feeling of apprehension or anxiety, visual changes, and marked increase in systolic and diastolic blood pressure
 - common triggers
 - ♦ urinary system: bladder distention, urinary tract infection, and kidney stones
 - ♦ GI causes: fecal impaction or bowel distention
- treatment: monitoring and controlling blood pressure, prior to addressing causative issue
- cardiac
 - no autoregulation, falling BP, decreasing HR, vasodilation
 - management: give IV fluids ± vasopressors
- respiratory
 - no cough reflex (risk of aspiration pneumonia)
 - no intercostal muscles ± diaphragm movement
 - management: intubate and maintain vital capacity
- gastrointestinal
 - ileus, vasodilation, bile and pancreatic secretion continues (>1L/day): risk of aspiration, GI stress ulcers
 - management: NG tube may be required for suctioning, feeding, etc.
- renal
 - hypoperfusion → give IV fluids
 - kidney still producing urine (bladder can rupture if patient not urinating)
 - management: Foley catheter may be required (measure urine output)
- skin
 - vasodilation, heat loss, no thermoregulation, atrophy (risk of skin ulcers)
- muscle
 - flaccidity, atrophy, decreased venous return
- penis
 - priapism

Figure 4. C-Spine X-Ray; Odontoid View

Prevertebral soft tissue swelling is only 49% sensitive for injury.

20% of C-spine fractures are accompanied by other spinal fractures, so ensure thoracic and lumbar spine x-rays are normal before proceeding to OR.

Trauma to the chest accounts for 50% of trauma deaths.

80% of all chest injuries can be managed non-surgically with simple measures such as intubation, chest tubes, and pain control.

3-way Seal for Open Pneumothorax (i.e. sucking chest wound)
Allows air to escape during the expiratory phase (so that you don't get a tension pneumothorax) but seals itself to allow adequate breaths during the inspiratory phase.

Chest Trauma

- two types
 - A. found and managed in 1° survey
 - B. found and managed in 2° survey

A. Life-Threatening Chest Injuries Found in 1° Survey (see Table 6)

Table 6. Life-Threatening Chest Injuries Found in 1° Survey

	Physical Exam	Investigations	Management
Airway Obstruction	<ul style="list-style-type: none"> • Anxiety, stridor, hoarseness, altered mental status • Apnea, cyanosis 	<ul style="list-style-type: none"> • Do not wait for ABG to intubate 	<ul style="list-style-type: none"> • Definitive airway management • Intubate early • Remove FB if visible with laryngoscope prior to intubation
Tension Pneumothorax	<ul style="list-style-type: none"> • Clinical diagnosis • One-way valve causing accumulation of air in pleural space 	<ul style="list-style-type: none"> • Non-radiographic diagnosis 	<ul style="list-style-type: none"> • Needle thoracostomy – large bore needle, 2nd ICS mid clavicular line, followed by chest tube in 5th ICS, anterior axillary line
Open Pneumothorax	<ul style="list-style-type: none"> • Gunshot or other wound (hole > 2/3 tracheal diameter) ± exit wound • Unequal breath sounds 	<ul style="list-style-type: none"> • ABG: decreased pO₂ 	<ul style="list-style-type: none"> • Air-tight dressing sealed on 3 sides • Chest tube • Surgery
Massive Hemothorax	<ul style="list-style-type: none"> • >1500 cc blood loss in chest cavity 	<ul style="list-style-type: none"> • Usually only able to do supine CXR – entire lung appears radioopaque as blood spreads out over posterior thoracic cavity 	<ul style="list-style-type: none"> • Restore blood volume • Chest tube • Thoracotomy if: <ul style="list-style-type: none"> ▪ >1500 cc total blood loss ▪ ≥200 cc/hr continued drainage

**DDx of Life Threatening Chest Injuries****HOT and FAT CHEST**

Hemothorax*
Open pneumothorax
Tension pneumothorax*

Flail chest
Airway obstruction
Tamponade*

Contusion: pulmonary, myocardial
Hernia: traumatic, diaphragmatic
ESophageal perforation
Tracheobronchial disruption/
Traumatic injury/Thoracic Aorta
Rupture*

*Rapidly Life Threatening

**Kussmaul's Sign Causes:**

Constrictive pericarditis
Right ventricular myocardial infarction
Tricuspid stenosis
Cardiac Tamponade

Ruptured diaphragm is more often diagnosed on the left side, as liver conceals right side defect.

**Aortic Tear: ABC WHITE**

X-ray features of Aortic tear
depressed left mainstem Bronchus
pleural Cap
Wide mediastinum (most consistent)
Hemothorax
Indistinct aortic knuckle
Tracheal deviation to right side
Esophagus (NG tube) deviated to right
(Note: present in 85% of cases, but cannot rule out)

**If Penetrating Neck Trauma present, DON'T:**

- Clamp structures (can damage nerves)
- Probe
- Insert NG tube (leads to bleeding)
- Remove weapon/impaled object

Table 6. Life-Threatening Chest Injuries Found in 1° Survey (continued)

	Physical Exam	Investigations	Management
Flail Chest <ul style="list-style-type: none">• Free-floating segment of chest wall due to >2 rib fractures, each at 2 sites• Underlying lung contusion (cause of morbidity and mortality)	<ul style="list-style-type: none">• Paradoxical movement of flail segment• Palpable crepitus of ribs• Decreased air entry on affected side	<ul style="list-style-type: none">• ABG: decreased pO₂, increased pCO₂• CXR: rib fractures, lung contusion	<ul style="list-style-type: none">• O₂ + fluid therapy + pain control• Judicious fluid therapy in absence of systemic hypotension• Positive pressure ventilation• ± intubation and ventilation
Cardiac Tamponade <ul style="list-style-type: none">• Clinical diagnosis• Pericardial fluid accumulation impairing ventricular function	<ul style="list-style-type: none">• Penetrating wound (usually)• Beck's triad: hypotension, distended neck veins, muffled heart sounds• Tachycardia, tachypnea• Pulsus paradoxus• Kussmaul's sign	<ul style="list-style-type: none">• Echocardiogram• Bedside ultrasound (FAST)	<ul style="list-style-type: none">• IV fluids• Pericardiocentesis• Open thoracotomy

B. Potentially Life-Threatening Chest Injuries Found in 2° Survey (see Table 7)

- need to have high index of suspicion, usually dependent on mechanism of injury

Table 7. Potentially Life-Threatening Chest Injuries Found in 2° Survey

	Physical Exam	Investigations	Management
Pulmonary Contusion	<ul style="list-style-type: none"> • Blunt trauma to chest • Interstitial edema impairs compliance and gas exchange 	<ul style="list-style-type: none"> • CXR: areas of opacification of lung within 6 hours of trauma 	<ul style="list-style-type: none"> • Maintain adequate ventilation • Monitor with ABG, pulse oximeter and ECG • Chest physiotherapy • Positive pressure ventilation if severe
Ruptured Diaphragm	<ul style="list-style-type: none"> • Blunt trauma to chest or abdomen (e.g. high lap belt in MVC) 	<ul style="list-style-type: none"> • CXR: abnormality of diaphragm/lower lung fields/NG tube placement • CT scan and endoscopy – sometimes helpful for diagnosis 	<ul style="list-style-type: none"> • Laparotomy for diaphragm repair and because of associated intra-abdominal injuries
Esophageal Injury	<ul style="list-style-type: none"> • Usually penetrating trauma (pain out of proportion to degree of injury) 	<ul style="list-style-type: none"> • CXR: mediastinal air (not always) • Esophagram (Gastrografin) • Flexible esophagoscopy 	<ul style="list-style-type: none"> • Early repair (within 24 hrs) improves outcome but all require repair
Aortic Tear	<ul style="list-style-type: none"> • Sudden high speed deceleration (e.g. MVC, fall, airplane crash), complaints of chest pain, dyspnea, hoarseness (frequently absent) • Decreased femoral pulses, differential arm BP (arch tear) 	<ul style="list-style-type: none"> • CXR, CT scan, transesophageal echo (TEE), aortography (gold standard) • See sidebar for CXR features 	<ul style="list-style-type: none"> • Thoracotomy (may treat other severe injuries first)
Blunt Myocardial Injury (rare)	<ul style="list-style-type: none"> • Blunt trauma to chest (usually in setting of multi-system trauma and therefore difficult to diagnose) • Physical examination: overlying injury, e.g. fractures, chest wall contusion 	<ul style="list-style-type: none"> • ECG: arrhythmias, ST changes • Patients with a normal ECG and normal hemodynamics never get dysrhythmias 	<ul style="list-style-type: none"> • O₂ • Antiarrhythmic agents • Analgesia

C. Other Potentially Life-Threatening Injuries Related to the Chest**Penetrating Neck Trauma**

- includes all penetrating trauma to the three zones of the neck (Figure 5)
- management: injuries deep to platysma require further evaluation by angiography, contrast CT or surgery
- do not explore penetrating neck wounds except in the OR

Airway Injuries

- always maintain a high index of suspicion
- larynx
 - history: strangulation, clothes line, direct blow, blunt trauma, any penetrating injury involving platysma
 - triad: hoarseness, subcutaneous emphysema, palpable fracture crepitus
 - other symptoms: hemoptysis, dyspnea, dysphonia
 - investigations: CXR, CT scan, arteriography (if penetrating)
 - management
 - ♦ airway – manage early because of edema
 - ♦ C-spine may also be injured, consider mechanism of injury
 - ♦ surgical – tracheotomy vs. repair
- trachea/bronchus
 - frequently missed
 - history: deceleration, penetration, increased intra-thoracic pressure; complaints of dyspnea, hemoptysis
 - examination: subcutaneous air, Hamman's sign (crunching sound synchronous with heart beat)
 - CXR: mediastinal air, persistent pneumothorax or persistent air leak after chest tube inserted for pneumothorax
 - management: surgical repair if >1/3 circumference

Figure 5. Zones of the Neck in Trauma

Abdominal Trauma

- two mechanisms
 - blunt: usually causes solid organ injury (spleen injury is most common)
 - penetrating: usually causes hollow organ injury or liver injury (most common)

BLUNT TRAUMA

- results in two types of hemorrhage
 - intra-abdominal bleed
 - retroperitoneal bleed
- adopt high clinical suspicion of bleeding in multi-system trauma

History

- mechanism of injury, SAMPLE history

Physical Exam

- often unreliable in multi-system trauma
 - slow blood loss not immediately apparent
 - other injuries may mask symptoms
 - serial examinations are required
- abdomen
 - inspect: contusions, abrasions, seatbelt sign, distention
 - auscultate: bruits, bowel sounds
 - palpate: tenderness, rebound tenderness, rigidity, guarding
 - DRE: rectal tone, blood, bone fragments, prostate location
 - placement of NG, foley catheter should be considered part of the abdo exam
- other systems to assess: CVS, respiratory (possibility of diaphragm rupture), pelvis, back, neuro as it pertains to abdo sensation, GU

Investigations

- labs: CBC, electrolytes, coags, cross & type, glucose, creatinine, CK, lipase, amylase, liver enzymes, ABG, blood EtOH, β -hCG, U/A, tox screen
- imaging: see Table 8

Table 8. Imaging in Abdominal Trauma

Imaging	Strengths	Limitations
X-Ray	Chest (looking for free air under diaphragm, diaphragmatic hernia, air-fluid levels), pelvis, cervical, thoracic, lumbar spines	Soft tissue not well visualized
CT scan	Most specific test	Radiation exposure 20x more than x-ray Cannot use if hemodynamic instability
Diagnostic Peritoneal Lavage (DPL)	Most sensitive test Tests for intra-peritoneal bleed	Cannot test for retroperitoneal bleed or diaphragmatic rupture Cannot distinguish lethal from trivial bleed Results can take up to 1 hr
Ultrasound: FAST (Focused Abdominal Sonogram for Trauma)	Identifies presence/absence of free fluid in peritoneal cavity RAPID exam: less than 5 minutes Can also examine pericardium and pleural cavities	NOT used to identify specific organ injuries If patient has ascites, FAST will be falsely positive

Seatbelt Injuries may Cause

- Retroperitoneal duodenal trauma
- Intraperitoneal bowel transection
- Mesenteric injury
- L-spine injury

Indications for Foley and NG Tube in Abdominal Trauma

Foley catheter: unconscious or patient with multiple injuries who cannot void spontaneously.

Contraindications: blood at the meatus, an ecchymotic scrotum, or a "high-riding" prostate on DRE (retrograde cystourethrogram is indicated to rule out a urethral tear or ruptured bladder).

NG tube: used to decompress the stomach and proximal small bowel.

Contraindications: facial fractures or basal skull fractures suspected.

Criteria for Positive Lavage

- >10 cc gross blood
- Bile, bacteria, foreign material
- RBC count > 100,000 x 10⁶/L
- WBC > 500 x 10⁶/L, amylase > 175 IU

Laparotomy is Mandatory if Penetrating Trauma and:

- Shock
- Peritonitis
- Evisceration
- Free air in abdomen
- Blood in NG tube, Foley catheter, or on rectal exam

"Rule of Thirds" for stab wounds:

- 1/3 do not penetrate peritoneal cavity
- 1/3 penetrate but are harmless
- 1/3 cause injury requiring surgery

Gross hematuria suggests bladder injury.

In the case of gross hematuria, the GU system is investigated from distal to proximal (i.e. urethrogram, cystogram, etc.)

- imaging must be done if
 - equivocal abdominal examination, suspected intra-abdominal injury or distracting injuries
 - multiple trauma patient resulting in unreliable physical exam (altered sensorium, e.g. secondary to drugs, alcohol, head trauma, or distracting injury; spinal cord injury resulting in abdominal anesthesia)
 - unexplained shock/hypotension
 - multiple trauma patients who must undergo general anesthesia for orthopaedic, neurosurgical, or other injuries
 - fractures of lower ribs, pelvis, spine
 - positive FAST

Management

- general: ABCs, fluid resuscitation and stabilization
- surgical: watchful wait vs. laparotomy
- solid organ injuries: decision based on hemodynamic stability, not the specific injuries
- hemodynamically unstable or persistently high transfusion requirements: laparotomy
- hollow organ injuries: laparotomy
- even if low suspicion on injury: admit and observe for 24 hours

PENETRATING TRAUMA

- high risk of gastrointestinal perforation and sepsis
- history: size of blade, calibre/distance from gun, route of entry
- local wound exploration under direct vision may determine lack of peritoneal penetration (not reliable in inexperienced hands) with the following exceptions:
 - thoracoabdominal region (may cause pneumothorax)
 - back or flanks (muscles too thick)

Management

- general: ABCs, fluid resuscitation and stabilization
- gunshot wounds → always require laparotomy

Genitourinary Tract Injuries

- see Urology, U32

Etiology

- blunt trauma – often associated with pelvic fractures
 - renal contusions (minor injury – parenchymal ecchymoses with intact renal capsule)
 - renal parenchymal tears/laceration: non-communicating (hematoma) vs. communicating (urine extravasation, hematuria)
 - extraperitoneal rupture of bladder from pelvic fracture fragments
 - intraperitoneal rupture of bladder from trauma and full bladder
 - anterior (bulbous) urethral damage with pelvic fractures
 - ureter: rare, at uretero-pelvic junction
- penetrating trauma
 - damage to: kidney, bladder, ureter (rare)
- acceleration/deceleration injury
 - renal pedicle injury – high mortality rate (laceration and thrombosis of renal artery, renal vein, and their branches)
- iatrogenic
 - ureter (from instrumentation)

History

- mechanism of injury
- hematuria (microscopic or gross), blood on underwear
- dysuria, urinary retention
- history of hypotension

Physical Examination

- abdominal pain, flank pain, costovertebral angle (CVA) tenderness, upper quadrant mass, perineal lacerations
- DRE: sphincter tone, position of prostate, presence of blood
- scrotum: ecchymoses, lacerations, testicular disruption, hematomas
- bimanual exam, speculum exam
- extraperitoneal bladder rupture: pelvic instability, suprapubic tenderness from mass of urine or extravasated blood
- intraperitoneal bladder rupture: acute abdomen

Investigations

- urethra: retrograde urethrography
- bladder: urinalysis, CT scan, urethrogram, \pm retrograde cystoscopy, \pm cystogram (distended bladder + post-void)
- ureter: retrograde ureterogram
- renal: CT scan (best, if hemodynamically stable), intravenous pyelogram (IVP)

Management

- urology consult
- renal
 - minor injuries – conservative management
 - ♦ bedrest, hydration, analgesia, antibiotics
 - major injuries – admit
 - ♦ conservative management with frequent reassessments, serial urinalysis, \pm reimaging
 - ♦ surgical repair (exploration, nephrectomy): e.g. hemodynamically unstable or continuing to bleed >48 h, major urine extravasation, renal pedicle injury, all penetrating wounds and major lacerations, infections, renal artery thrombosis
- ureter
 - uretero-uretostomy
- bladder
 - extraperitoneal
 - ♦ minor rupture: Foley drainage x 10-14 days
 - ♦ major rupture: surgical repair
 - intraperitoneal
 - ♦ drain abdomen and surgical repair
- urethra
 - anterior: conservative, if cannot void \rightarrow Foley or suprapubic cystostomy and antibiotics
 - posterior: suprapubic cystostomy (avoid catheterization) \pm surgical repair

Orthopaedic Injuries

- see [Orthopaedics](#) (*Shoulder, Knee, Wrist, Ankle*)

Goals of ED Treatment

- identify injuries accurately and address potentially life/limb threatening problems appropriately
- reduce and immobilize fractures (cast/splint) as appropriate
- provide adequate pain relief
- arrange proper follow-up if necessary

History

- use SAMPLE
- mechanism of injury may be very important

Physical Examination

- **Look** (inspection): “SEADS” Swelling, Erythema, Atrophy, Deformity, Skin changes (e.g. bruises)
- **Feel** (palpation): all joints/bones – local tenderness, swelling, warmth, crepitus, joint effusions, subtle deformity
- **Move**: joints affected plus above and below injury – active ROM preferred to passive
- **Neurovascular status**: distal to injury (BEFORE and AFTER reduction)

LIFE AND LIMB THREATENING INJURIES (see Table 9)

- threat to life is usually due to blood loss (e.g. up to 3 L in pelvic fractures, 1.5 L per long bone fracture)
- threat to limb is usually due to interruption of blood supply to distal part of limb or to susceptible part of bone

Table 9. Life and Limb Threatening Orthopedic Injuries

Life Threatening Injuries	Limb Threatening Injuries
Major pelvic fractures	Fracture/dislocation of ankle (talar AVN)
Traumatic amputations	Crush injuries
Massive long bone injuries (beware of fat emboli)	Compartment syndrome
Vascular injury proximal to knee/elbow	Open fractures
	Dislocations of knee/hip
	Fractures above knee/elbow

Description of Fractures

SOLARTAT

Site
Open vs. closed
Length
Articular
Rotation
Translation
Alignment/Angulation
Type (e.g. Salter-Harris, etc.)

Reasons for Emergent Orthopaedic Consultation

- Compartment syndrome
- Irreducible dislocation
- Circulatory compromise
- Open fracture
- Injury requiring surgical repair

When Dealing with an Open Fracture, Remember "STAND"

Splint
Tetanus prophylaxis
Antibiotic
Neurovascular status (before and after)
Dressings (to cover wound)

Vascular injury/compartament syndrome is suggested by "The 6 Ps":

Pulse discrepancies
Pallor
Paresthesia/hypoesthesia
Paralysis
Pain (especially when refractory to usual analgesics)
Polar (cold)

Open Fractures

- communication between fracture site and external surface of skin – risk of osteomyelitis
- remove gross debris, irrigate, cover with sterile dressing – formal irrigation and debridement often done in the OR
- control bleeding with pressure (no clamping)
- splint
- antibiotics (1st generation cephalosporin and aminoglycoside) and tetanus prophylaxis
- must secure definitive surgical care within 6-8 hours

Vascular Injuries

- realign limb/apply longitudinal traction and reassess pulses (e.g. Doppler probe)
- surgical consult
- direct pressure if external bleeding

Compartment Syndrome

- increased interstitial pressure in an anatomical "compartment" (forearm, calf) with little room for expansion, resulting in decreased perfusion and potential muscle/nerve necrosis
- **excessive** pain which is worse with passive stretching and refractory to analgesia is the hallmark sign early on; also look for "the 6 Ps" (see side bar)
- requires prompt decompression – remove constrictive casts, dressings; fasciotomy may be needed emergently

UPPER EXTREMITY INJURIES

- anterior shoulder dislocation
 - axillary nerve (lateral aspect of shoulder) and musculocutaneous nerve (extensor aspect of forearm) at risk
 - seen on lateral view: humeral head anterior to glenoid
 - ♦ reduce (traction, scapular manipulation), immobilize in internal rotation, repeat x-ray, out-patient follow-up with ortho
 - ♦ with forceful injury, look for fracture
- Colles' fracture (Figure 6)
 - distal radius fracture with dorsal displacement from Fall On an Outstretched Hand (FOOSH)
 - AP film: shortening, radial deviation, radial displacement
 - lateral film: dorsal displacement, volar angulation
 - reduce, immobilize with splint, out-patient follow-up with ortho or immediate orthopedic referral if complicated fracture
 - if involvement of articular surface, emergent orthopedic referral
- scaphoid fracture (see Figure 7 for review of carpal bones)
 - tenderness in anatomical snuff box, pain on scaphoid tubercle, pain on axial loading of thumb
 - negative x-ray: thumb spica splint, re-x-ray in 1 week ± bone scan
 - positive x-ray: thumb spica splint x 6-8 weeks, re-x-ray in 2 weeks
 - risk of avascular necrosis (AVN) of scaphoid if not immobilized
 - outpatient ortho follow-up

Figure 6. Colles' Fracture

Figure 7. Carpal Bones

LOWER EXTREMITY INJURIES

- ankle and foot fractures
 - see Ottawa Ankle and Foot Rules (Figure 8)
- knee injuries
 - see Ottawa Knee Rules (Figure 9)
- avulsion of the base of 5th metatarsal
 - occurs with inversion injury
 - supportive tensor or below knee walking cast for 3 weeks
- calcaneal fracture
 - associated with fall from height
 - associated injuries may involve ankles, knees, hips, pelvis, lumbar spine

A knee x-ray examination is required only for acute injury patients with one or more of:

- Age 55 years or older
- Tenderness at head of fibula
- Isolated tenderness of patella*
- Inability to flex to 90°
- Inability to bear weight both immediately and in the emergency department (four steps)**

*no bony tenderness of knee other than patella

**unable to transfer weight twice onto each lower limb regardless of limping

Figure 9. Ottawa Knee Rules

Adapted from: Stiell et. al. *JAMA* 1997; 278:2075-2079

Wound Management

Goals of ED Treatment

- identify injuries and stop any active bleeding – direct pressure
- manage pain
- wound examination and exploration (history and physical)
- cleansing ± antibiotic and tetanus prophylaxis
- repair and dressing

Tetanus Prophylaxis

- both tetanus toxoid (Td) and immunoglobulin (TIG) are safe (and indicated) in pregnancy

Table 10. Guidelines for Tetanus Prophylaxis for Wounds

Immunization History	Non Tetanus Prone Wounds		Tetanus Prone Wounds ¹	
	Td ²	TIG ³	Td	TIG
Uncertain or <3 doses	Yes	No	Yes	Yes
3 or more, none for >10 years	Yes	No	Yes	No
3 or more, 5 to 10 years ago	No	No	Yes	No
3 or more, <4 years ago	No	No	Yes	No

¹ wounds >6 hours old, >1 cm deep, puncture wounds, avulsions, wounds resulting from missiles, crush wounds, burns, frostbite, wounds contaminated with dirt, feces, soil, or saliva

² 0.5 mL IM tetanus and diphtheria toxoids (Td), adsorbed

³ tetanus immune globulin (TIG), 250 units deep IM

Source: *MMWR* 2001; 50(20):418-427. *MMWR* 1991; 40(RR12):1-52.

Bruises

- non palpable = ecchymosis
- palpable collection (not swelling) = hematoma following blunt trauma
- assess for coagulopathy (e.g. liver disease), anticoagulant use

Reasons for Splinting

- Reduces pain
- Reduces further damage to vessels and nerves
- Reduces risk of inadvertently converting a closed fracture into an open fracture
- Facilitates patient transport

Accuracy of Ottawa Ankle Rules to Exclude Fractures of the Ankle and Mid-Foot: Systematic Review

BMJ 2003; 326(7386):417

This systematic review and meta-analysis of 27 studies including 15,581 patients evaluated the sensitivity and specificity of the Ottawa ankle rules for excluding fractures of the ankle and mid-foot.

Results: The pooled likelihood ratio of a negative result (obtaining a false negative) among those with a fracture was determined to be 0.08 for both the ankle and mid-foot.

Reviewers' Conclusions: The Ottawa ankle rules provide an accurate instrument for excluding fractures of the ankle and mid-foot with a sensitivity of almost 100% and a specificity of 26%. The use of this instrument can reduce the number of unnecessary radiographs.

Acute Treatment of Contusions

RICE

Rest
Ice
Compression
Elevation

Suture Use and Duration

Suture to	Close with nylon or other nonabsorbable suture	Approx. duration (days)
Face	6-0	5
Not Joint	4-0	7
Joint	3-0	10
Scalp	4-0	7
Mucous Membrane	absorbable (vicryl)	N/A

N.B. Patients on steroid therapy may need sutures in for longer periods of time

Alternatives to Sutures

- Tissue glue
- Steristrips®
- Staples

Where **NOT** to use local anesthetic with epinephrine:
Ears, Nose, Fingers, Toes and Nose (Penis)

Differential Diagnosis of Cellulitis
Necrotizing Fasciitis
Gas gangrene
Cutaneous anthrax
Vaccinia vaccination
Insect bite (hypersensitivity)
Acute gout
DVT
Fixed drug eruption
Kawasaki's
Pyoderma gangrenosum

Features of Necrotizing Fasciitis Infection

ABCDE

- A** – Anaerobic, Aerobic, Adult, Antibiotics refractory
- B** – Bacterial synergistic gangrene, Blood count higher than normal
- C** – Cellulitis, Crepitus, and Coagulopathy
- D** – Dermal gangrene, Delay in presentation almost fatal
- E** – Erythema with spreading Edema

Abrasions

- partial to full thickness break in skin
- management
 - clean thoroughly, ± local anesthetic, with brush to prevent foreign body impregnation (tattooing)
 - antiseptic ointment (Polysporin® or Vaseline®) for 7 days for facial and complex abrasions
 - tetanus prophylaxis (Table 10)

Lacerations

- see also Plastic Surgery, PL6
- consider every structure deep to a laceration injured until proven otherwise
- in hand injury patients, include following in history: handedness, occupation, mechanism of injury, previous history of injury
- physical exam
 - think about underlying anatomy
 - examine tendon function actively against resistance and neurovascular status distally
 - clean and explore under local anesthetic; look for partial tendon injuries
 - x-ray or ultrasound wounds if a foreign body is suspected (e.g. shattered glass) and not found when exploring wound (remember: not all foreign bodies are radiopaque), or if suspect intra-articular involvement
- management
 - disinfect skin/use sterile techniques
 - irrigate copiously with normal saline
 - analgesia ± anesthesia (Figure 10)
 - maximum dose of lidocaine:
 - ♦ 7 mg/kg with epinephrine
 - ♦ 5 mg/kg without epinephrine
- in children, topical anesthetics such as LET (lidocaine, epinephrine and tetracaine) and in selected cases a short-acting benzodiazepine (midazolam or other agents) for sedation and amnesia are useful
- secure hemostasis
- evacuate hematomas, debride non-viable tissue, remove hair and remove foreign bodies
- ± prophylactic antibiotics
- suture unless delayed presentation, a puncture wound, or mammalian bite
- take into account patient and wound factors when considering suturing
- advise patient when to have sutures removed

Figure 10. Digital Block – Local Anesthesia of Digits

Early wound irrigation and debridement are the most important factors in decreasing infection.

Cellulitis

- see also Plastic Surgery, PL12
- localized infection of the dermis
- bacterial (*S. aureus*, GAS, *H. influenzae*, occasionally *Pseudomonas* spp., MRSA) infection of skin and subcutaneous tissues
- look for “rubor, calor, dolor, tumour” (erythema, warmth, pain, swelling)
- have high index of suspicion in patients who are immunocompromised (e.g. HIV, DM), vasculopathies, IV drug users
- treat with immobilization and elevation of infected area, antibiotics, analgesics, and close follow-up
- antibiotics for mild cellulitis: PO cephalexin or cloxacillin
- if MRSA: PO clindamycin, doxycycline, TMP-SMX; IV vancomycin if bacteremic

Abscess

- may be associated with a retained foreign body
- look for warm, swollen, painful, erythematous fluctuant masses
- ensure absence of systemic symptoms and presence of subcutaneous air in simple abscesses
- anesthetize locally
- treat with incision and drainage ± antibiotics – apply warm compress, give analgesics

Which Abscesses Need Antibiotics?

- Evidence of systemic illness (e.g. cellulitis)
- Immunocompromised patient
- Patient at risk for endocarditis

Trauma in Pregnancy

- priorities: Airway, Breathing, Circulation

Hemodynamic Considerations

- near term, inferior vena caval compression in the supine position can decrease cardiac output by 30-40% (see *Maternal Physiology*, *Obstetrics*, OB3)
 - use left lateral decubitus (LLD) positioning or hip bolster to alleviate compression and increase blood return if BP is low
- BP drops 5-15 mmHg systolic in 2nd trimester, increases to normal by term
- HR increases 15-20 beats per minute by 3rd trimester

Blood Considerations

- physiologic macrocytic anemia of pregnancy (Hb 100-120)
- WBC increases to high of 20,000

Shock

- pregnant patients may lose 35% of blood volume without typical signs of shock (i.e. tachycardia, hypotension)
- the fetus may be in "shock" due to contraction of the uteroplacental circulation
- fetal HR changes are an early warning of maternal circulatory compromise

Management Differences

- place bolster under right hip to stop inferior vena cava compression
- fetal monitoring (continuous tocographic monitoring if possible viable fetus >20 weeks)
- early obstetrical consult
- do not avoid necessary x-rays, but shield as much as possible
- consider need for RhoGAM if mother Rh negative

The best treatment for the fetus is the effective treatment of the mother.

Approach to Common ER Presentations

Abdominal Pain

Rule Out Life-Threatening Causes

- CVS: MI, aortic dissection, ruptured AAA (tearing pain)
- GI: perforated viscus, hepatic/splenic injury, ischemic bowel (diffuse pain)
- gynecologic: ectopic pregnancy

Additional Differential Diagnosis

- GI: appendicitis, diverticulitis, bowel obstruction, hepatitis, cholecystitis, pancreatitis
- urinary: cystitis, pyelonephritis, ureteral calculi
- genital
 - female: pelvic inflammatory disease (PID)/salpingitis, tubo-ovarian abscess, ovarian torsion, ovarian cyst, endometriosis
 - male: testicular torsion, epididymitis
- other: diabetic ketoacidosis (DKA), Herpes Zoster Virus (HZV), intra-abdominal abscess, pneumonia, lead poisoning, porphyria, sickle cell crisis, psychiatric

History and Physical Examination

- determine onset, course, location and character of pain: PQRST
- broad differential, including GU, Gyne, GI, respiratory, and CV systems
- recent/remote abdominal trauma/surgeries
- general appearance, vitals, ABCs
- respiratory, CVS
- abdomen and back: CVA tenderness, ecchymoses, stigmata of liver disease, DRE, pelvic exam (females), genital exams (males)
- extremities: differential pulses, psoas/obturator sign

Investigations

- do not delay consultation if patient unstable
- CBC, electrolytes, glucose, LFTs, amylase, BUN/creat, U/A, + others if indicated: β -hCG, ECG, troponins
- AXR: look for calcifications, free air, gas pattern, air fluid levels
- CXR upright: look for pneumoperitoneum (free air under diaphragm)
- U/S: biliary tract, ectopic pregnancy, AAA, free fluid
- CT: trauma, AAA, pancreatitis, nephro/urolithiasis, appendicitis and diverticulitis

Red Flags

- Extremes of age
- Unstable vital signs
- Fever
- Signs/symptoms of shock
- Rapid onset severe pain

Abdominal Assessment in all 4 Quadrants

DR. GERM

Distention
Rigidity
Guarding
Evisceration/Ecchymosis
Rebound tenderness
Masses

If both AST and ALT elevated,
AST > ALT indicates potential alcohol
related hepatic diseases
ALT > AST indicates viral hepatic
pathology
If ALP and GGT elevated, think
biliary tree

Old age, pregnancy (T3), and chronic corticosteroid use can blunt peritoneal findings, so have increased suspicion of intrabdominal process in these individuals!

Unstable patients should not be sent for imaging.

All women of childbearing age assumed to be pregnant until proven otherwise.

Gynecological Causes of Pelvic Pain:

Ovarian Cyst
Dysmenorrhea
Mittelschmerz
Endometriosis
Ovarian Torsion
Uterine Fibroids/neoplasm
Adnexal Neoplasm
PID + Cervicitis

Ultrasound is the preferred imaging modality in the assessment of acute pelvic pain.

Management

- NPO, IV, NG tube, analgesics
 - growing evidence that small amounts of narcotic analgesics improve diagnostic accuracy of physical exam of surgical abdomen
- consult as necessary: general surgery, vascular, gynecology, etc.

Disposition

- admission: in addition to a surgical abdomen, admission is sometimes required for workup of abnormal findings on investigation, IV antibiotics, pain control, etc.
- discharge: patients with a negative lab and imaging workup who improve clinically during their stay; instruct the patient to return if severe pain, fever, or persistent vomiting develop

Acute Pelvic Pain

Etiology

- gynecological
 - 2nd most common gynecological complaint after vaginal bleeding
 - ruptured ovarian cysts – most common cause of pelvic pain, follicular cyst most common type
 - ovarian torsion – rare, 50% will have ovarian mass
 - leiomyomas (uterine fibroids) – especially with torsion of a pedunculated fibroid or in pregnant patient (degeneration)
 - ectopic pregnancy – ruptured/expanding/leaking
 - spontaneous abortion – threatened or incomplete
 - infection – PID, endometritis, tubo-ovarian abscess
 - dysmenorrhea and endometriosis
- non-gynecological
 - GI – appendicitis, constipation, bowel obstruction, gastroenteritis, diverticulitis, IBD, IBS
 - GU – cystitis, pyelonephritis, ureteric stone
 - other – porphyria, abdominal angina, aneurysm, hernia, zoster

History and Physical Exam

- determine onset, course, location and character of the pain
- associated symptoms: vaginal bleeding, bowel or bladder symptoms, radiation
- vitals
- gynecological exam
- abdominal exam

Investigations

- β -hCG for all women of childbearing age
- CBC and differential, PTT/INR
- pelvic and abdominal U/S – evaluate adnexa, look for free fluid in the pelvis or masses, evaluate thickness of endometrium
- doppler flow studies for ovarian torsion

Management

- general: analgesia, determine if admission and consults needed
 - gynecology consult if history and physical suggestive of serious cause
 - other consults as indicated – general surgery, urology, etc.
- specific:
 - ovarian cysts
 - ♦ unruptured or ruptured and hemodynamically stable – analgesia and follow-up
 - ♦ ruptured with significant hemoperitoneum – may require surgery
 - ovarian torsion – surgical detorsion or removal of ovary
 - uncomplicated leiomyomas, endometriosis and secondary dysmenorrhea can usually be treated on an outpatient basis, discharge with gynecology follow-up
 - PID: requires broad spectrum antibiotics

Disposition

- patients requiring IV therapy or surgery should be admitted
- patients to be discharged should be given clear instructions for appropriate follow-up

Altered Level of Consciousness (LOC)

Definitions

- altered mental status – collective, non-specific term referring to change in cognitive function, behaviour, or attentiveness
- delirium – acute, transient, fluctuating, potentially reversible organic brain disorder presenting as altered LOC and attentiveness (see [Psychiatry](#), PS17)
- dementia – insidious, progressive, organic brain disorder with change in memory, judgment, personality and cortical function (see [Psychiatry](#), PS18)
- lethargy – state of decreased awareness and alertness (patient may appear wakeful)
- stupor – unresponsiveness from which the patient can be aroused
- coma – a sleep-like state, not arousable to consciousness (Figure 11)
- use the GCS to evaluate LOC (see *Initial Patient Assessment and Management*, ER2)

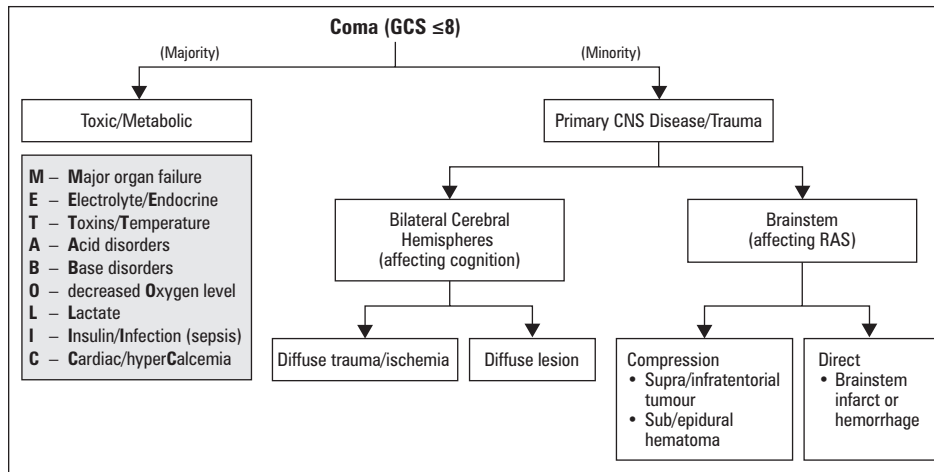

Figure 11. Etiology of Coma

Possible Causes of Coma

AEIOU TIPS

Acidosis/Alcohol
Epilepsy
Infection
Oxygen (hypoxia)/Opiates
Uremia
Temperature/Trauma (especially head)
Insulin (too little or too much)
Psychogenic/Poisoning
Stroke

MANAGEMENT OF ALTERED LOC

History

- obtained from family, friends, police, paramedics, old chart, etc.
- onset and progression
 - abrupt onset suggests CNS hemorrhage/ischemia or cardiac cause
 - progression over hours to days suggests progressive CNS lesion or toxic/metabolic cause
- preceding events
 - it is essential to determine patient's baseline LOC preceding deterioration
 - antecedent trauma, seizure activity, fever
- past medical history (e.g. similar episode, depression, overdose)

Physical Examination

- ABC's, vitals including temperature, cardiac, chest, respiratory, abdominal exam, and the "five Ns" (see sidebar)
- complete neuro exam, in particular examination of the eyes, look for medic alert bracelet

Investigations

- rapid blood sugar, CBC, electrolytes, Cr, BUN, LFTs, glucose, serum osmolality, ABGs, coags, troponins, U/A
- ECG, CXR, CT head
- drug levels of specific toxins if indicated

Diagnosis

- administer appropriate universal antidotes
 - thiamine 100 mg IV if history of EtOH or patient looks malnourished
 - one ampule D50W IV if low blood sugar on finger-prick
 - naloxone 0.4-2 mg IV or IM if opiate overdose suspected
- distinguish between structural and toxic-metabolic coma
 - structural coma
 - pupils, extraocular movements and motor findings, if present, are usually asymmetric
 - look for focal or lateralizing abnormalities
 - toxic-metabolic coma
 - dysfunction at lower levels of the brainstem (e.g. caloric unresponsiveness)
 - respiratory depression in association with an intact upper brainstem (e.g. equal and reactive pupils; see exceptions in Table 11)
 - extraocular movements and motor findings are symmetric or absent

In general, GCS under 8, intubate, but ability to protect airway is primary consideration!

Evaluation of Comatose Patient

Five Ns

Noggin
e.g. raccoon eyes and Battle's sign (bruising of the mastoid process) appears about 8 hours after trauma

Neck
C-spine, neurogenic shock, nuchal rigidity

ENT
Otorrhea, rhinorrhea, tongue biting, odour on breath, hemotympanum

Needles
Inspect for track marks

Neurological
Concentrate on GCS, respiration, posture, movement, pupils, reflexes

Universal Antidotes

DON'T

Dextrose
Oxygen
Naloxone 2 mg
Thiamine 100 mg

- essential to re-examine frequently – status can change rapidly
- diagnosis may become apparent only with the passage of time
 - delayed deficit after head trauma suggestive of epidural hematoma (characteristic “lucid interval”)

Table 11. Toxic – Metabolic Causes of Fixed Pupils

Dilated	Dilated to Normal	Constricted
Anoxia	Hypothermia	Cholinergic agents (e.g. organophosphates)
Anticholinergic agents (e.g. atropine, TCAs)	Barbiturates	Opiates (e.g. heroin), except meperidine
Methanol (rare)	Antipsychotics	
Cocaine		
Opioid withdrawal		
Amphetamines		
Hallucinogens		

Disposition

- readily reversible alteration of LOC: discharge if adequate follow-up care available
- ongoing decreased LOC: admit to service based on tentative diagnosis
- transfer patient if appropriate level of care not available

Chest Pain

**Life Threatening causes of Chest Pain****PET MAP**

Pulmonary embolism
Esophageal rupture
Tamponade
MI/angina
Aortic dissection
Pneumothorax

Imaging is necessary for all suspected aortic dissections, regardless of blood pressure.

**Signs and Symptoms of MI****PULSE**

Persistent chest pain
Upset stomach
Lightheadedness
Shortness of breath
Excessive sweating

**PERC score for PE**

Age > 50 years
HR > 100 bpm
O₂ sat on RA < 94%
Prior history DVT/PE
Recent trauma or surgery
Hemoptysis
Exogenous estrogen
Clinical signs suggesting DVT

Score 1 for each question; a score 0/8 means patient has < 1.6% chance having a PE and avoids further investigation.

Rule Out Life-Threatening Causes

- CVS: acute coronary syndrome/acute MI, pericarditis/cardiac tamponade, aortic dissection
- respiratory: pulmonary embolism (PE)/pneumothorax (tension or spontaneous)
- GI: esophageal rupture/pneumomediastinum

Additional Differential Diagnosis

- cardiac: stable angina
- respiratory: pneumonia
- GI: peptic ulcer disease (PUD), pancreatitis, cholecystitis, esophagitis, reflux, esophageal spasm
- MSK: rib fractures, costochondritis, zoster, etc.
- psychogenic/anxiety (diagnosis of exclusion)

Initial Resuscitation and Management

- O₂, IV, cardiac monitoring, CXR (portable if unstable), ECG

History

- must evaluate cardiac risk factors (DM, HTN, hyperlipidemia, smoking, family history)
- classic presentations (but presentation seldom classic)
 - aortic dissection: syncope with sudden severe tearing pain, often radiating to back, ± focal pain/neurologic loss in extremities secondary to major vessel ischemia
 - pulmonary embolism: pleuritic chest pain (75%), dyspnea, anxiety, tachycardia, PERC SCORE
 - pericarditis: anterior precordial pain, pleuritic, relieved by sitting up and leaning forward
 - acute coronary syndrome (ACS): retrosternal squeezing/pressure pain, radiation to arm/neck, dyspnea, nausea/vomiting, syncope
 - esophageal: frequent heartburn, acid reflux, dysphagia, relief with antacids
- ACS more likely to be atypical in females, diabetics, and >80 years

Physical Examination

- vitals (BP in both arms, but unreliable indicator of dissection)
- palpate chest wall for tender points, but be aware that 25% of patients with acute MI have chest wall tenderness
 - consider a diagnosis of MSK disease only if more serious causes excluded and palpation fully reproduces pain and symptoms
- cardiac exam, respiratory exam, peripheral vascular exam

Investigations

- CBC, electrolytes
- serial cardiac enzymes
 - normal CK-MB does NOT rule out MI
 - troponin I more sensitive (but positive later than CK-MB; can have false positives in renal failure, must follow for 8 hrs post onset of symptoms)
- ECG (see Table 12)
 - always compare with previous
 - PE and acute MI may have normal ECG in up to 50% of cases
 - consider 15-lead ECG if hypotensive or if ECG shows inferior MI or AV node involvement

- CXR
 - always compare with previous
 - PE (see DVT, ER34)
 - ♦ 50% completely normal
 - ♦ atelectasis, elevated hemidiaphragm, pleural effusion
 - aortic dissection (see sidebar ER12 for features)
 - ♦ change from previous CXR is the most accurate finding
 - ♦ CXR is normal in 20% of thoracic dissections
 - pneumothorax
 - ♦ may need inspiration and expiration views
- ABGs – normal in 20% of patients with PE, therefore do not perform
- D-dimer, V/Q scan or helical CT, venous leg Doppler, if PE suspected (see sidebar for *Wells' Score*)
- negative D-dimer rules out PE in low probability patients
- patients with intermediate or high probability Wells' score require imaging

Disposition

- patients at risk of developing dysrhythmias should be admitted to a monitored bed
- consult cardiology for patients with ACS; obtain a cardiothoracic surgery consultation for patients with valvular lesions by echocardiogram, esophageal rupture, or aortic dissection
- discharge is appropriate for patients with a low probability of life-threatening illness due to resolving symptoms and negative workup; instruct the patient to return if they develop SOB or increased chest pain

Table 12. Common Life Threatening ECG Changes

Pathology	ECG Findings
Dysrhythmia	
a) Torsade de Pointes	Ventricular complexes in upward-pointing and downward-pointing continuum (250-350 bpm)
b) Ventricular tachycardia	6 or more consecutive premature ventricular beats (150-250 bpm)
c) Ventricular flutter	Smooth sine wave pattern of similar amplitude (250-350 bpm)
d) Ventricular fibrillation	Erratic ECG tracing, no identifiable waves
Conduction	
a) 2nd degree heart block (Mobitz Type II)	PR interval stable, some QRS's dropped
b) 3rd degree heart block	Total AV dissociation, but stable P-P and R-R intervals
c) Left bundle branch block	Prolonged QRS complex (>0.12s) RSR' in V5 or V6 Monophasic I and V6 May see ST elevation Difficult to interpret, new LBBB is considered STEMI equivalent
Ischemia	
a) STEMI	ST elevation in leads associated with injured area of heart and reciprocal lead changes (depression)
Metabolic	
a) Hyperkalemia	Tall T waves P wave flattening QRS complex widening and flattening
b) Hypokalemia	U waves appear Flattened T waves
Digitalis Toxicity	
	Gradual downward curve of ST At risk for AV blocks and ventricular irritability
Syndromes	
a) Brugada	RBBB with ST elevation in V1, V2 and V3 Susceptible to deadly arrhythmias, including V. Fib.
b) Wellens	Marked T wave inversion in V2 and V3 Left anterior descending coronary stenosis
c) Long QT Syndrome	QT interval longer than ½ of cardiac cycle Predisposed to ventricular arrhythmia

ACUTE MYOCARDIAL INFARCTION

- see *Cardiology*, C25

Management

- immediate stabilization
 - oxygen 4L/min
 - IV access
 - cardiac monitors
 - STAT ECG
 - cardiac enzymes (CK, Troponins)
- ASA 162-325 mg chewed
- nitroglycerin 0.3 mg SL q5min x 3 (IV for CHF, HTN, unresolved pain)
- morphine 2-5 mg IV q5-30min if unresponsive to NTG
- metoprolol 5 mg slow IV q5min x 3 if no contraindication (beware in inferior wall AMI)

Signs of PE on CXR

Westermark's sign: abrupt tapering of a vessel on chest film.

Hampton's hump: a wedge-shaped infiltrate that abuts the pleura.

Wells' Score for PE

Previous Hx of DVT/emboli	+1.5
HR >100	+1.5
Recent immobility or Sx	+1.5
Clinical signs of DVT	+3
Alternate Dx less likely than PE	+3
Hemoptysis	+1
Cancer	+1

Low probability = 0-2

Intermediate probability = 2-6

High probability = >6

Important to look for reciprocal changes in STEMI in order to differentiate from pericarditis (diffuse elevations).

Immediate Treatment of Acute MI

BEMOAN
 Beta-Blockade
 Enoxaparin
 Morphine
 Oxygen
 ASA
 Nitroglycerin

Addition of Clopidogrel to Aspirin and Fibrinolytic Therapy for Myocardial Infarction with ST-Segment Elevation

NEJM 2005; 352(12):1179-1191

Purpose: To assess the benefit of adding clopidogrel to aspirin and fibrinolytic therapy in ST-elevation MI.

Study Characteristics: Double-blind, RCT, following intention-to-treat analysis, with 3491 patients and clinical follow-up at 30 days.

Participants: Individuals presenting within 12 hours of onset of ST-elevation MI (mean age 57, 80.3% male, 50.3% smokers, 9.1% previous MI). Those presenting after 12 hours, age >75, or with previous CABG were excluded.

Intervention: Clopidogrel (300 mg loading dose followed by 75 mg od until day of angiogram) or placebo, in addition to aspirin, a fibrinolytic agent, and heparin when appropriate.

Primary Outcome: Composite of occluded infarct-related artery on angiography (Thrombolysis in Myocardial Infarction flow grade 0 or 1), or death or recurrent MI prior to angiography.

Results: Rates of primary end point were 21.7% in the placebo group and 15.0% in the clopidogrel group (95% CI, 24-47%). Among the individual components of the primary end point, clopidogrel had a significant effect on the rate of an occluded infarct-related artery and the rate of recurrent MI, but no effect on the rate of death from any cause. At 30 days clinical follow-up, there was no difference in rate of death from cardiovascular causes, a significant reduction in the odds of recurrent MI, and a non-significant reduction in recurrent ischemia with need for urgent revascularization. The rates of major bleeding and intracranial hemorrhage were similar between the two groups.

Conclusion: Addition of clopidogrel improves the patency rate of infarct-related arteries and reduces ischemic complications, both of which are associated with improved long-term survival after MI. The trial was not powered to detect a survival benefit and none was seen.

- low molecular weight heparin 1 mg/kg SC bid (30 mg IV STAT post TNK infusion)
- thrombolytics or primary percutaneous coronary intervention (PCI)
 - agents include t-PA, r-PA, Streptokinase, and TNK
 - evaluate indications and contraindications prior to use
- other – antiarrhythmics, cardioversion, defibrillation, transthoracic pacing, angioplasty
- cardiology consult

Epistaxis

- see Otolaryngology, OT27
- 90% of nosebleeds stem from the anterior nasal septum (at Kiesselbach's plexus located in Little's area)
- can be life-threatening

Etiology

- most commonly caused by trauma (digital, blunt, foreign bodies), but can also be caused by barometric changes, nasal dryness, chemicals (cocaine, Otrivin®), or systemic disease (coagulopathies, hypertension, etc.)

Investigations

- CBC, PT/PTT (if indicated)
- x-ray, CT as needed

Treatment

- aim is to localize bleeding and achieve hemostasis
- first-aid: ABC's, lean forward, pinch soft part of nose for 20 minutes
- assess blood loss: vitals, IV normal saline, cross match 2 units packed RBC if significant
- determine site of bleeding: use topical anaesthetic/vasoconstrictor to facilitate; use nasal speculum and good lighting
- attempt to control the bleeding
 - first line: Otrivin® or cocaine
 - second line: cauterize with silver nitrate (one side of septum only!)
 - if these fail, or if bleeding is posterior → nasal packing (must monitor for complications)
 - if packing fails, consult ENT

Disposition

- most patients can be discharged after ensuring vitals are stable, bleeding is controlled and patient has appropriate follow-up
- educate patients about prevention (e.g. humidifiers, saline spray, topical ointments, avoiding irritants, managing hypertension)
- admission may be required for severe cases

Thrombocytopenic patients – use resorbable packs to avoid risk of re-bleeding caused by pulling out the removable pack.

Complications of Nasal Packing
Hypoxemia
Toxic-shock syndrome
Aspiration
Pharyngeal fibrosis/stenosis
Alar/septal necrosis

Headache

- see also Neurology, N39

Etiology

- **the common**
 - common migraine (no aura)/classic migraine (involves aura)
 - ♦ gradual onset, unilateral/bilateral, throbbing
 - ♦ nausea/vomiting, photo/phonophobia
 - ♦ treatment: analgesics, neuroleptics, vasoactive meds
 - tension/muscular headache
 - ♦ never during sleep, gradual over 24 hours
 - ♦ posterior/occipital
 - ♦ increased with stressors
 - ♦ treatment: modify stressor, local measures, NSAIDs, tricyclic antidepressants
- **the deadly**
 - subarachnoid hemorrhage (SAH) (see Neurosurgery, NS17)
 - ♦ sudden onset, increased with exertion
 - ♦ “worst” headache, nausea and vomiting, meningeal signs
 - ♦ diagnosis: CT, LP (5-10% of patients with SAH have negative initial CT)
 - sensitivity of CT decreases with time and is much less sensitive by 48-72 hr
 - ♦ management: urgent neurosurgery consult
 - increased ICP
 - ♦ worst in morning, supine, or bending down
 - ♦ physical exam: neurological deficits, cranial nerve palsies, papilledema
 - ♦ diagnosis: CT scan
 - ♦ management: consult neurosurgery

Note: up to 5% of patients with subarachnoid hemorrhage have a normal CT scan; if suspect SAH with a negative CT, perform a lumbar puncture.

BEWARE: every headache is serious until proven otherwise.

DDx Subarachnoid Hemorrhage
BATS
Berry aneurysm
Arteriovenous malformation/Adult polycystic kidney disease
Trauma
Stroke

- meningitis (see [Infectious Diseases](#), ID6)
 - ♦ flu-like presentation initially (fever, nausea/vomiting, malaise), meningeal signs, purpuric rash
 - ♦ altered level of consciousness and confusion
 - ♦ perform CT to rule out increased ICP then do LP for diagnosis
 - ♦ treatment: early empiric antibiotics (depending on age group), steroid therapy
- temporal arteritis (not immediately deadly but causes great morbidity) (see [Ophthalmology](#), OP38)
 - ♦ unilateral scalp tenderness, jaw claudication, visual disturbances
 - ♦ labs: elevated ESR
 - ♦ temporal artery biopsy is gold standard for diagnosis
 - ♦ treatment: high-dose steroids immediately if TA suspected

**Meningitis**

Do not delay IV antibiotics for LP.

Disposition

- admit if underlying diagnosis is critical or emergent, if there are abnormal neurological findings, if patient is elderly or immunocompromised (atypical presentation), or if pain is refractory to oral medications
- most patients can be discharged with appropriate analgesia and follow up with their family physician; instruct patients to return for fever, vomiting, neurologic changes, or increasing pain

Joint Pain

- see [Rheumatology](#)

Rule Out Life-Threatening Causes

- septic joint (see [Orthopaedics](#), OR8)

Differential Diagnosis

- articular pain
 - monoarticular
 - ♦ infectious: bacterial, viral, fungal
 - ♦ hemarthrosis: trauma/fracture, anticoagulants, bleeding diatheses
 - ♦ crystal induced: gout, CPPD, hydroxyapatite
 - ♦ inflammatory: seropositive, seronegative
 - ♦ neoplasm
 - ♦ degenerative: osteoarthritis
 - polyarticular
 - ♦ infectious: Lyme disease, bacterial endocarditis, septicemia, *gonococcus*, viral
 - ♦ post-infectious: rheumatic fever, reactive arthritis, enteric infections
 - ♦ inflammatory: seropositive, seronegative
 - ♦ degenerative: osteoarthritis
- non-articular
 - musculoskeletal
 - ♦ localized: tendonitis, bursitis, capsulitis, muscle sprain
 - ♦ generalized: fibromyalgia, PMR
- other
 - neurologic: spinal stenosis/spondylolithesis, degenerative disc disease, cauda equina syndrome, neoplasm, thoracic outlet syndrome, Charcot joint
 - vascular: intermittent claudication

**Causes of Joint Pain****SOFTER TISSUE**

Sepsis
 Osteoarthritis
 Fractures
 Tendon/muscle
 Epiphyseal
 Referred

 Tumour
 Ischemia
 Seropositive arthritides
 Seronegative arthritides
 Urate
 Extra-articular rheumatism
 (e.g. polymyalgia)

History and Physical Examination

- determine onset, course, location, character of the pain (OPQRST) and recurrence
- determine which joint or joints are involved
- associated symptoms: fever, constitutional symptoms, skin lesions, conjunctivitis, urethritis
- patterns of joint involvement: polyarticular vs. monoarticular, symmetric vs. asymmetric
- inflammatory symptoms: prolonged morning stiffness, stiffness and pain ease through the day, midday fatigue, soft tissue swelling
- non-inflammatory symptoms: stiffness short lived after inactivity, short duration stiffness in the morning, pain increases with activity
- assess ROM, presence of joint effusion, warmth
- watch for: localized joint pain, erythema, warmth, swelling with pain on active ROM, inability to bear weight, fever as these may indicate presence of septic joint

Investigations

- x-ray, CBC, ESR, CRP, WBC, INR/PTT, blood cultures, urate
- joint aspirate → send for: WBC, protein, glucose, Gram stain, crystals

Management

- septic joint: IV antibiotics \pm joint decompression and drainage
 - antibiotics can be started empirically if septic arthritis cannot be ruled out
- crystalline synovitis: NSAIDs at high dose, colchicine within first 24 hours, corticosteroids
 - do not use allopurinol, as it may worsen acute attack
- acute polyarthritis: NSAIDs, analgesics (acetaminophen \pm opioids), corticosteroids local or systemic
 - hospitalization is required in the presence of (1) significant, concomitant internal organ involvement; (2) signs of bacteremia, including vesiculopustular skin lesions, Roth spots, shaking chills, or splinter hemorrhages; (3) systemic vasculitis; (4) severe pain; (5) severe constitutional symptoms; (6) purulent synovial fluid in one or more joints; or (7) immunosuppression
- osteoarthritis: acutely: NSAIDs, acetaminophen
- soft tissue pain: allow healing with enforced rest \pm immobilization
 - nonpharmacologic treatment: local heat or cold, electrical stimulation, massage
 - pharmacologic: oral analgesics, NSAIDs, muscle relaxants, corticosteroid injections, topical agents

Otalgia

Differential Diagnosis (see also Otolaryngology, OT6)

- local
 - infections: AOE, AOM, OM with effusion, mastoiditis, myringitis, malignant otitis in diabetics, herpes simplex/zoster, auricular cellulites, external canal abscess
 - others: trauma, neoplasm, foreign body, cerumen impactions, Wegener's
- determine onset, course, location and character of pain
- otorrhea, aural fullness, hearing loss, pruritis
- Q-tip use, hearing aids, headphones
- associated symptoms: fever
- observe for otorrhea, palpation of outer ear, otoscope to see bulging erythematous TM, perforation

Investigations

- consider audiogram if hearing loss

Management

- debridement and antibiotics for cerumen and infection

Seizures

- see Neurology, N8

Definition

- paroxysmal alteration of behaviour and/or EEG changes resulting from abnormal, excessive activity of neurons

Categories

- generalized seizure (consciousness always lost): tonic/clonic, absence, myoclonic, atonic
- partial seizure (focal): simple partial, complex partial
- causes: trauma, intracranial hemorrhage, structural abnormality, infection, toxins/drugs, metabolic disturbance (hypo/hyperglycemia, hypo/hyponatremia, hypocalcemia, hypomagnesemia); primary seizure disorder
- differential diagnosis: syncope, pseudoseizures, migraines, movement disorder, narcolepsy/cataplexy, myoclonus

History

- from patient and bystander: flaccid and unconscious, often with deep rapid breathing
- preceding aura, rapid onset, loss of bladder/bowel control, tongue-biting (sides of the tongue)

Physical Examination

- injuries to head and spine and bony prominences (e.g. elbows), tongue laceration, aspiration, urinary incontinence

Investigations

- known seizure disorder: anticonvulsant levels
- Accu-Chek®
- first time seizure: CBC, serum glucose, electrolytes, BUN, creatinine, Ca, Mg; consider prolactin, β -hCG, tox screen
- initial: CT; x-ray if suspected extremity injuries. Definitive: MRI, EEG

Min. Workup in an Adult with 1st Time Seizure
 CBC and diff
 Electrolytes including Ca, Mg, PO₄
 Head CT

Table 13. Management of Status Epilepticus

Time (min)	Steps
0-5	Give oxygen; ensure adequate ventilation Monitor: vital signs, electrocardiography, oximetry Establish IV access; obtain blood samples for glucose level, CBC, electrolytes, toxins, and anticonvulsant levels
6-9	Give 50 mL 50% glucose (preceded by thiamine 100 mg IM in adults)
10-20	IV lorazepam 0.1 mg/kg at 2 mg/min or IV diazepam 0.2 mg/kg at 5 mg/min Diazepam can be repeated if seizures do not stop after 5 min; if diazepam is used to stop the status, then phenytoin should be administered promptly to prevent the recurrence of status
21-60	If status persists, administer 15-20 mg/kg of phenytoin intravenously no faster than 50 mg/min in adults and 1 mg/kg/min in children
>60	If status does not stop after 20 mg/kg of phenytoin, give additional doses of 5 mg/kg to a maximal dose of 30 mg/kg. If status persists, then give 20 mg/kg of phenobarbital IV at 100 mg/min. When phenobarbital is given after a benzodiazepine, ventilatory assistance is usually required If status persists, then give general anaesthesia (e.g., pentobarbital). Vasopressors or fluid volume are usually necessary. Electroencephalogram should be monitored. Neuromuscular blockade may be needed.

Adapted from: *Cecil's Essentials of Medicine*, 7th edition, Table 125-7. Used with permission.

Disposition

- the decision to admit or discharge should be based on the underlying disease process identified
 - if a patient has returned to baseline function and is neurologically intact, then consider discharge with outpatient follow-up
- first-time seizure patients being discharged should be referred to a neurologist for follow-up
- admitted patients should generally have a neurology consult
- patient should not drive until medically cleared (local regulations vary)
 - complete notification form to appropriate authority re: ability to drive
- warn regarding other safety concerns (e.g. no swimming, bathing children alone, etc.)

Shortness of Breath

- see [Respirology](#) and [Cardiology](#)

Etiology

- categorized into one of two groups: respiratory or cardiovascular
- respiratory system dyspnea: discomfort related to disorders of the central controller (brain), the ventilatory pump (ventilatory muscles, peripheral nerves), and the gas exchanger (alveoli and pulmonary capillaries)
- cardiovascular system dyspnea: cardiac diseases (acute ischemia, heart failure, systolic dysfunction, valvular disorders, pericardial diseases), anemia, and deconditioning

History/Physical

- acute SOB is often due to a relatively limited number of conditions. Associated symptoms and signs are key to the appropriate diagnosis
 - substernal chest pain with cardiac ischemia
 - fever, cough and sputum with respiratory infections
 - urticaria with anaphylaxis
 - wheezing with acute bronchospasm
- dyspnea may be the sole complaint and the physical examination may reveal few abnormalities (e.g. pulmonary embolism, pneumothorax)
- chest tightness may be indicative of bronchospasm
- a sensation of rapid, shallow breathing may correspond to interstitial disease
- a sense of heavy breathing is typical of deconditioning
- vitals including pulse oximetry
 - wheeze (airway) vs. crackles (parenchymal), JVP, and murmurs

Investigations

- CBC + differential (hematocrit to exclude anemia), electrolytes, consider ABG
- CXR (hyperinflation and bullous disease suggestive of obstructive lung disease, or changes in interstitial markings consistent with inflammation, infection or interstitial fluid)
- serial cardiac enzymes and ECG if considering cardiac source
- CT chest usually is not indicated in the initial evaluation of patients with dyspnea, but can be valuable in patients with interstitial lung disease, occult emphysema, or chronic thromboembolic disease (PE)

Disposition

- the history and physical examination lead to accurate diagnoses in patients with dyspnea in approximately two-thirds of cases; the decision to admit or discharge should be based on the underlying disease process identified
 - consideration for intubation should be early in CO₂ retainers (e.g. COPD)
- if the decision to discharge is chosen, provide appropriate discharge instructions to return in case of returning/worsening SOB

If administering phenytoin, patient must be on a cardiac monitor as arrhythmias and/or hypotension may occur.

Causes of Acute Dyspnea

Cardiovascular: acute MI, CHF, cardiac tamponade.

Respiratory: bronchospasm, pulmonary embolism, pneumothorax, infection (bronchitis, pneumonia), upper airway obstruction (aspiration, anaphylaxis).

Contraindication to 100% Oxygen
CO₂ retainers (e.g. COPD).

Syncope

5 Types of Syncope

1. Vasomotor
2. Cardiac
3. CNS
4. Metabolic
5. Psychogenic

Causes of Syncope by System

HEAD, HEART, VeSSELS

Hypoxia/Hypoglycemia
Epilepsy
Anxiety
Dysfunctional brainstem

Heart attack
Embolism (PE)
Aortic obstruction
Rhythm disturbance
Tachycardia

Vasovagal
Situational
Subclavian steal
ENT (glossopharyngeal neuralgia)
Low systemic vascular resistance
Sensitive carotid sinus

Definition

- sudden, transient loss of consciousness and postural tone with spontaneous recovery
- usually caused by generalized cerebral or reticular activating system hypoperfusion

Etiology

- cardiogenic: arrhythmia, outflow obstruction (e.g. PE, tamponade, tension pneumothorax, pulmonary HTN), MI, valvular disease
- non-cardiogenic: peripheral vascular (hypovolemia), vaso-vagal, cerebrovascular disorders, CNS, metabolic disturbances (e.g. EtOH intoxication)

History

- gather details from witnesses, and clarify patient's experience (e.g. dizziness, ataxia, or true syncope)
- distinguish between syncope and seizure (see Neurology, N9)
 - some patients may have myoclonic jerks with syncope – NOT a seizure
 - signs and symptoms during presyncope, syncope and postsyncope
 - past medical history, drugs
 - think anatomically in differential; pump (heart), blood (quality), vessels, brain
- sudden loss of consciousness with no warning or prodrome is cardiogenic until proven otherwise

Physical Examination

- postural BP and HR
- cardiovascular, respiratory and neuro exam
- physical findings in the elderly patient who falls (**I HATE FALLING**):
 - Inflammation of joints (or joint deformity)
 - Hypotension (orthostatic blood pressure changes)
 - Auditory and visual abnormalities
 - Tremor (Parkinson's disease or other causes of tremor)
 - Equilibrium (balance) problem
 - Foot problems
 - Arrhythmia, heart block or valvular disease
 - Leg-length discrepancy
 - Lack of conditioning (generalized weakness)
 - Illness
 - Nutrition (poor; weight loss)
 - Gait disturbance

Investigations

- ECG (tachycardia, bradycardia, blocks, WPW, long QT interval), bedside glucose
- as indicated: CBC, electrolytes, BUN, creatinine, ABGs, Troponin, Ca, Mg, β -hCG
- consider drug screen

Management

- ABCs, IV, O₂, monitor
- examine for signs of trauma caused by syncopal episode
- cardiogenic syncope: admit to medicine/cardiology
- non-cardiogenic syncope: discharge with follow-up as indicated by cause

Disposition

- decision to admit is based on etiology
- most patients will be discharged
- on discharge, instruct patient to follow up with family physician
 - educate re: avoiding orthostatic or situational syncope
 - patients with recurrent syncope should avoid high-risk activities (e.g. driving)

Sexual Assault

Legally required to report sexual assault if victim is <16 years of age to Children's Aid Society (CAS).

Epidemiology

- 1 in 4 women and 1 in 10 men will be sexually assaulted in their lifetime
- it is estimated that only 7% of rapes are reported

General Approach

- ABCs, treat acute, serious injuries
- ensure patient is not left alone and provide ongoing emotional support
- set aside adequate time for exam (usually 1.5 hours)

- obtain consent for medical exam and treatment, collection of evidence, disclosure to police (notify police as soon as consent obtained)
- Sexual Assault Kit (document injuries, collect evidence) if <72 hrs since assault
- label samples immediately and pass directly to police
- offer community crisis resources (e.g. shelter, hotline)
- do not report unless victim requests (legally required if <16 years old)

History

- ensure privacy for the patient – others should be asked to leave
- questions to ask: who? how many? when? where did penetration occur? what happened? any weapons or physical assault?
- post-assault activities (urination, defecation, change of clothes, shower, douche, etc.)
- gynecologic history
 - gravity, parity, last menstrual period
 - contraception use
 - last voluntary intercourse (sperm motile 6-12 hours in vagina, 5 days in cervix)
- medical history – acute injury/illness, chronic diseases, psychiatric history, medications, allergies, etc.

Physical Examination

- evidence collection is always secondary to treatment of serious injuries
- never re-traumatize a patient with the examination
- general examination
 - mental status
 - sexual maturity
 - patient should remove clothes and place in paper bag
 - document abrasions, bruises, lacerations, torn frenulum/broken teeth (indicates oral penetration)
- pelvic exam and specimen collection
 - ideally before urination or defecation
 - examine for seminal stains, hymen, signs of trauma
 - collect moistened swabs of dried seminal stains
 - pubic hair combings and cuttings
 - speculum exam
 - ♦ lubricate with water only
 - ♦ vaginal lacerations, foreign bodies
 - ♦ Pap smear
 - ♦ oral/cervical/rectal culture for gonorrhea and chlamydia
 - ♦ posterior fornix secretions if present or aspiration of saline irrigation
 - ♦ immediate wet smear for motile sperm
 - ♦ air-dried slides for immotile sperm, acid phosphatase, ABO group
- others
 - fingernail scrapings
 - saliva sample from victim

Investigations

- VDRL – repeat in 3 months if negative
- serum β -hCG
- blood for ABO group, Rh type, baseline serology (e.g. hepatitis, HIV)

Management

- involve local/regional sexual assault team
- medical
 - suture lacerations
 - tetanus prophylaxis
 - gynecology consult for foreign body, complex lacerations
 - assumed positive for gonorrhea and chlamydia
 - ♦ management: azithromycin 1 g PO x 1 dose (alt: doxycycline 100 mg PO bid x 7 days) and cefixime 400 mg PO x 1 dose
 - may start prophylaxis for hepatitis B and HIV
 - pre and post counselling for HIV testing
 - pregnancy prophylaxis offered
 - ♦ levonorgestrel 0.75 mg PO STAT, repeat within 12 hours (Plan B®)
- psychological
 - high incidence of psychological sequelae
 - have victim change and shower after exam completed

Disposition

- discharge if injuries/social situation permit
- follow-up with MD in rape crisis centre within 24 hours
- best if patient does not leave ED alone

Risk of Sexually Transmitted Disease After Sexual Assault

Gonorrhea: 6-18%
Chlamydia: 4-17%
Syphilis: 0.5-3%
HIV: <1%

How do you get a patient who is accompanied by her partner alone without arousing suspicion?
Order an x-ray.

DOMESTIC VIOLENCE

- women are usually the victims, but male victimization also occurs
- identify the problem (need high index of suspicion)
 - suggestive injuries (bruises, sprains, abrasions, occasionally fractures, burns or other injuries; often do not match up with history provided)
 - somatic symptoms (chronic and vague complaints)
 - psychosocial symptoms
 - clinician impression (your 'gut feeling', e.g. overbearing partner that won't leave patient's side)
- if disclosed, be supportive and assess danger
- order an x-ray to secretly get patient alone to question re: abuse
- patient must consent to follow-up investigation/reporting (unless for children)

Management

- treat injuries
- ask about sexual assault and children at home
- document findings
- safety plan
- follow-up: family doctor/social worker

Medical Emergencies

Anaphylaxis and Allergic Reactions

Most Common Triggers for Anaphylaxis

- Penicillin
- Stings
- Nuts
- Shellfish

Etiology

- exaggerated immune response classically IgE mediated, sensitization then re-exposure
- anaphylaxis: a severe hypersensitivity reaction affecting at least two organ systems (e.g. GI, derm, resp)
- urticaria: a hypersensitivity reaction causing an itchy skin eruption
- angioedema: swelling that occurs in the tissue just below the surface of the skin, most often around the lips and eyes
- anaphylactoid reaction: non-IgE mediated, may occur with first exposure (e.g. radiocontrast dyes); presentation and treatment same as for anaphylaxis

History and Physical Examination

- general – marked anxiety, apprehension, tremor, cold sensation
- skin – generalized urticaria, edema, erythema, pruritus
- GI – abdominal pain, nausea, vomiting, diarrhea (most allergens are ingested, therefore GI symptoms common)
- respiratory – nasal congestion, sneezing, coryza, cough, hoarseness, sensation of throat tightness, dyspnea, stridor, wheeze
- eyes – itch, tearing, conjunctival injection
- cardiovascular – hypotension, tachycardia, weakness, dizziness, syncope, chest pain, arrhythmia, MI

Management

- remove causative agent; secure ABCs
- epinephrine
 - on scene – epi-pen (injectable epinephrine) if available
 - moderate signs and symptoms (minimal airway edema, mild bronchospasm, cutaneous reactions)
 - ♦ adult: 0.3-0.5 mL of 1:1000 solution IM epinephrine
 - ♦ child: 0.01 mL/kg/dose up to 0.4 mL/dose 1:1000 epinephrine
 - severe signs and symptoms (laryngeal edema, severe bronchospasm and shock, severe hypotension)
 - ♦ epinephrine via IV or ETT starting at 1 mL of 1:10,000 (0.1 mg) in adults; 0.01 mL/kg in children
 - ♦ cardiac monitoring, ECG
- diphenhydramine (Benadryl®) 50 mg IM or IV q4-6h
- methylprednisolone 50-100 mg IV (dose depending on severity)
- salbutamol (Ventolin®) via nebulizer if bronchospasm
- glucagon (for those on β -blockers with resistant hypotension and/or cardiac disease) 5-15 μ g q1min IV

Disposition

- monitor for 4-6 hours in ED (minimum) and arrange follow up with family physician in 24-48 hours
- can have second phase (rebound) reaction up to 48 hours later, patient may need to be supervised
- 3-day course of:
 - H₁ antagonist (cetirizine 10 mg PO od)
 - H₂ antagonist (ranitidine 150 mg PO od)
 - corticosteroid (prednisone 50 mg PO od)

Treatment

- Airway control
- Epinephrine
- Establish IV and give fluids
- Steroids
- Anti-histamines

Asthma

- see Respirology, R7
- chronic inflammatory airway disease with episodes of bronchospasm and inflammation resulting in reversible airflow obstruction

Investigations

- O₂ sat
- peak flow meter
- \pm ABG (only in life threatening exacerbations)
- CXR if diagnosis in doubt or concerns of pneumonia, pneumothorax, etc.

Table 14. Asthma Assessment and Management

Classifications	History and Physical Examination	Management
Respiratory Arrest Imminent	<ul style="list-style-type: none"> • Exhausted, confused, diaphoretic, cyanotic • Silent chest, ineffective respiratory effort • Decreased HR • O₂ sat <90% despite supplemental O₂ 	<ul style="list-style-type: none"> • 100% O₂, cardiac monitor, IV access • Intubate (consider pre-induction with ketamine) • β-agonist: MDI 4–8 puffs OR nebulizer 5 mg continually • Anticholinergics: MDI 4–8 puffs q20 min x 3 OR nebulizer 0.5 mg q20 min x 3 • IV steroids: methylprednisolone 125 mg, hydrocortisone 500 mg
Severe Asthma	<ul style="list-style-type: none"> • Agitated, diaphoretic, laboured respirations • Difficulty speaking in full sentences • No relief from β-agonist • O₂ sat <90%, FEV₁ <50% 	<ul style="list-style-type: none"> • Anticipate need for intubation • Similar to above management (β-agonist may be less frequent; q15-20 min) • Magnesium sulphate 2 g IV
Moderate Asthma	<ul style="list-style-type: none"> • SOB at rest, cough, congestion, chest tightness • Nocturnal symptoms • Inadequate relief from β-agonist • FEV₁ 50-80% 	<ul style="list-style-type: none"> • O₂ to achieve O₂-sat >90% • β-agonist: puffer of neb q1h • Steroids: prednisone 40-60 mg PO • Anticholinergics (Atrovent)
Mild Asthma	<ul style="list-style-type: none"> • Exertional SOB/cough with some nocturnal symptoms • Good response to β-agonist • FEV₁ >80% 	<ul style="list-style-type: none"> • β-agonist • Monitor FEV₁ • Consider steroids (nebulized or PO)

Disposition

- β -agonist MDI regular use (2-4 puffs q2-4h) until symptoms controlled then prn
- prednisone 30-60 mg/day for 7-14 days with no taper
- inhaled steroid
- follow-up with primary care physician

Cardiac Dysrhythmias

- see Cardiology, C12

Bradyarrhythmias and AV Conduction Blocks

- AV conduction blocks
 - 1st degree – prolonged PR interval (>200 msec), no treatment required
 - 2nd degree
 - ♦ Mobitz I – gradual prolongation of PR then dropped QRS, usually benign
 - ♦ Mobitz II – PR constant with dropped QRS, can progress to 3rd degree AV block
 - 3rd degree – P unrelated to QRS, PP and RR intervals constant
 - ♦ atropine and transcutaneous pacemaker (TCP)
 - ♦ if TCP fails consider dopamine, epinephrine IV
 - long term treatment for Mobitz II and 3rd degree block – internal pacemaker
- sinus bradycardia (rate <60 bpm)
 - can be normal (especially in athletes)
 - causes: vagal stimulation, vomiting, myocardial infarction/ischemia, increased ICP, sick sinus node, hypothyroidism, drugs (e.g. β -blockers, CCBs)
 - treat if symptomatic (hypotension, chest pain)
 - ♦ acute: atropine \pm transcutaneous pacing
 - ♦ sick sinus: transcutaneous pacing
 - ♦ drug induced: discontinue/reduce offending drug

Beware of the silent asthmatic! This is a medical emergency and may require emergency intubation.

5 Essential Elements on History

- Cause of exacerbation
- Previous ER/ICU visits
- Previous intubations
- Timing of recent steroid use
- Frequency of asthma medication use

Treatment of Asthma

ASTHMA

Adrenergics (beta-agonists)

STeroids

Hydration

Mask (O₂)

Antibiotics (if concurrent infection)

Atropine is unlikely to work in 3rd degree heart block.

If the patient with tachyarrhythmia is unstable, perform immediate cardioversion.

Clinical Features of Instability

- Hypotension (sBP <90)
- CHF or pulmonary edema
- Chest pain
- Altered LOC (may indicate shock)

If patient has Wolff-Parkinson-White and is in AFib use amiodarone or procainamide. Avoid AV nodal blocking agents (adenosine, digoxin, diltiazem, verapamil) as this can increase conduction through bypass tract.

Use the CHADS2 score from Table 3, Cardiology, C17

Supraventricular Tachyarrhythmias (narrow QRS)

- sinus tachycardia (rate >100 bpm)
 - causes: increased sympathetic tone, drugs, fever, hypotension, anemia, thyrotoxicosis, MI, PE, emotional, pain, etc.
 - treat underlying cause, consider β -blocker if symptomatic
- regular rhythm
 - vagal manoeuvres (carotid massage, Valsava), adenosine 6 mg IV push, if no conversion give 12 mg, can repeat 12 mg dose once
 - rhythm converts: probable re-entry tachycardia
 - ♦ monitor for recurrence
 - ♦ treat recurrence with adenosine or longer acting medications
 - rhythm does not convert: atrial flutter, ectopic atrial tachycardia, junctional tachycardia
 - ♦ rate control (diltiazem, β -blockers) and consult cardiology
- irregular rhythm
 - probable atrial fibrillation, atrial flutter or multifocal atrial tachycardia
 - rate control (diltiazem, β -blockers)

Atrial Fibrillation

- most common sustained arrhythmia; no organized P waves, irregularly irregular heart rate, narrow QRS (typically)
- etiology: HTN, CAD, thyrotoxicosis, EtOH (holiday heart), valvular disease, pericarditis, cardiomyopathy, Sick Sinus Syndrome
- treatment principles: stroke prevention, treat symptoms, identify/treat underlying cause
- decreases cardiac output by 20-30% (due to loss of organized atrial contractions)
- acute management
 - if onset of AFib is >24-48 hrs: anticoagulate 3 wks prior to and 4 wks after cardioversion or do transesophageal echo to rule out clot
 - if symptomatic or first presentation – cardiovert
 - ♦ electrical cardioversion: synchronized DC cardioversion
 - ♦ chemical cardioversion: amiodarone, procainamide, flecainide, propafenone (if decreased LV function use amiodarone)
- long term management: rate or rhythm control, consider anticoagulation (CHADS2)

Ventricular Tachyarrhythmias (wide QRS)

- ventricular tachycardia (VT) (rate usually 140-200 bpm)
 - definition: 3 or more consecutive ventricular beats at >100 bpm
 - etiology: CAD with MI is most common cause
 - treatment: sustained VT (>30 seconds) is an emergency
 - ♦ hemodynamic compromise: DC cardioversion
 - ♦ no hemodynamic compromise: DC cardioversion, lidocaine, amiodarone, procainamide
- ventricular fibrillation – call a code blue, follow ACLS for pulseless arrest
- torsades de pointes
 - looks like VT but QRS ‘rotates around baseline’ with changing axis and amplitude (twisted ribbon)
 - etiology: prolonged QT due to drugs (e.g. quinidine, TCAs, erythromycin, quinolones), electrolyte imbalance (hypokalemia, hypomagnesemia), congenital
 - treatment:
 - ♦ IV Mg, temporary overdrive pacing, isoproterenol
 - ♦ correct cause of prolonged QT
 - ♦ discontinue cardioversion if hemodynamic compromise

Chronic Obstructive Pulmonary Disease (COPD)

- see [Respirology](#), R8
- progressive development of irreversible airway obstruction, typically caused by smoking
- acute exacerbation: episode of increased dyspnea, coughing, increase in sputum volume or purulence

History and Physical Examination

- worsening dyspnea or tachypnea
- acute change in frequency, quantity and colour of sputum production
- trigger: pneumonia, urinary tract infection, PE, CHF, MI, drugs

Investigations

- CBC, electrolytes, ABG, CXR, ECG, PFTs

Management

- keep O₂ sat 88-92% (beware of CO₂ retainers, but do not withhold O₂ if hypoxic)
- ipratropium is bronchodilator of choice, add salbutamol
- steroids: prednisone 40 mg PO (tapered over 3 weeks)
- antibiotics: TMP-SMX, cephalosporins, respiratory quinolones (if signs of infection)
- ICU admission if life-threatening with ventilation (chance of ventilation dependency)
- lower threshold to admit if co-morbid illness

Need to Rule Out with COPD Exacerbation

- Pneumothorax
- CHF exacerbation
- Acute MI
- Pneumonia and other infectious causes
- Pulmonary embolus

Disposition

- can use up to 4-6 puffs qid of ipratropium and salbutamol for exacerbations
- continue antibiotics if started and give tapering steroids

Congestive Heart Failure

- also see Cardiology, C32

Etiology

- decreased myocardial contractility: ischemia, infarction, cardiomyopathy, myocarditis
- pressure overload states: hypertension, valve abnormalities, congenital heart disease
- restricted cardiac output: myocardial infiltrative disease, cardiac tamponade
- volume overload

Causes of Exacerbation or Precipitants

- cardiac: acute myocardial infarction or ischemia, cardiac tachyarrhythmias (e.g. atrial fibrillation), uncontrolled hypertension
- medications: non-compliance with or change in cardiac medications, NSAIDs, steroids
- dietary: increased sodium intake
- increased cardiac output demand: infection, anemia, hyperthyroidism, pregnancy
- other: pulmonary embolus, physical overexertion, renal failure

History/Presentation

- left-sided heart failure
 - dyspnea, decreased exercise tolerance, paroxysmal nocturnal dyspnea, orthopnea, nocturia, fatigue, possibly altered mental status, syncope, systemic hypotension
 - in severe cases pulmonary edema: severe respiratory distress, pink frothy or white sputum, rales, S3 or S4
- right-sided heart failure
 - dependent edema, jugular venous elevation, hepatic enlargement, ascites
- patients often present with a combination of right-sided and left-sided symptoms

Physical Examination

- vitals: tachypnea, tachycardia, hypo- or hypertension, hypoxia
- respiratory: crackles (acute), wheeze (chronic)
- cardiac: laterally displaced apex, S3 or S4, jugular venous distention, hepato-jugular reflex
- abdominal: hepatomegaly, ascites
- peripheral vascular: peripheral or sacral edema, weak peripheral pulses, pulsus alternans (alternating weak and strong pulse), cool extremities

Investigations

- labs: CBC, electrolytes, AST, ALT, bilirubin, creatinine, BUN, cardiac enzymes, BNP (brain natriuretic peptide)
- chest X-ray (see side bar)
- ECG: look for MI, ischemia
 - in CHF: LVH, atrial enlargement, conduction abnormalities
- ABG: if severe or refractory to treatment
 - hypoxemia, hypercapnia and acidosis are signs of severe CHF
- echocardiogram: not usually used in emergency evaluation, previous results may aid in diagnosis
- may be precipitated by arrhythmia (e.g. sudden onset AFib) – correct if new

Management (acute)

- ABC, may require intubation if severe hypoxia
- sit upright, cardiac monitoring and continuous pulse oximetry
- saline lock IV, Foley catheter (to follow effectiveness of diuresis)
- 100% O₂ by mask
 - if poor response may require CPAP, BiPAP, or intubation
- drugs
 - nitro 0.3 mg SL q5min PRN ± topical nitro patch (0.2-0.8 mg/hr)
 - ♦ if not responding or ischemia: 10-200 µg/min IV, titrate
 - diuretic if volume overloaded (e.g. furosemide 40-80 mg IV)
 - morphine 1-2 mg IV prn
 - ♦ if hypotensive: dobutamine (2.5 µg/kg/min IV) or dopamine (5-10 µg/kg/min IV), titrate up to sBP 90-100
 - ASA 160 mg chew and swallow
- treat precipitating factor
- cardiology or medicine consult

**Causes of CHF Exacerbation****FAILURE**

Forgot medication
 Arrhythmia/Anemia
 Ischemia/Infarction/Infection
 Lifestyle (e.g. too much salt)
 Upregulation of cardiac output (pregnancy, hyperthyroidism)
 Renal failure
 Embolism (pulmonary)

**Hospital Management Required if:**

- Acute MI
- Pulmonary edema or severe respiratory distress
- Severe complicating medical illness (e.g. pneumonia)
- Anasarca
- Symptomatic hypotension or syncope
- Refractory to outpatient therapy
- Thromboembolic complications requiring interventions
- Clinically significant arrhythmias
- Inadequate social support for safe outpatient management
- Persistent hypoxia requiring supplemental oxygen

**CHF on CXR**

Pulmonary vascular redistribution
 Perihilar infiltrates
 Interstitial edema, Kerley B lines
 Alveolar edema, bilateral infiltrates
 May see cardiomegaly, pleural effusions

**Acute Treatment of CHF****LMNOP**

Lasix (furosemide)
 Morphine
 Nitroglycerine
 Oxygen
 Position (sit upright)

DVT and Pulmonary Embolism

Risk Factors for VTE THROMBOSIS

Trauma, travel
Hypercoagulable, HRT
Recreational drugs (IVDU)
Old (age > 60)
Malignancy
Birth control pill
Obesity, obstetrics
Surgery, smoking
Immobilization
Sickness (CHF, MI, nephrotic syndrome, vasculitis)

PERC score for PE

Age > 50 years
HR > 100 bpm
O₂ sat on RA < 94%
Prior history DVT/PE
Recent trauma or surgery
Hemoptysis
Exogenous estrogen
Clinical signs suggesting DVT

Score 1 for each question; a score 0/8 means patient has < 1.6% chance having a PE and avoids further investigation.

Wells Score for PE

Previous Hx of DVT/emboli	+1.5
HR > 100	+1.5
Recent immobility or Sx	+1.5
Clinical signs of DVT	+3
Alternate Dx less likely than PE	+3
Hemoptysis	+1
Cancer	+1

Low probability = 0-2
Intermediate probability = 2-6
High probability = > 6

D-dimer is only useful if it is negative.
Negative predictive value > 99%.

50% of patients with symptomatic proximal DVT will develop PE, often within days to weeks of the event.

- see also [Respirology](#), R18

Risk Factors

- Virchow's triad
 - alterations in blood flow (venous stasis)
 - injury to endothelium
 - hypercoagulable state (including pregnancy, use of OCP, malignancy)
- most significant risk factors (see side bar for complete list)
 - major surgery or trauma or prolonged hospitalization
 - permanent immobilization and age
 - malignancy, other hypercoagulable state
 - prior venous thromboembolism

History/Presentation

- DVT: calf pain, leg swelling/erythema/edema, palpable cord on exam; can be asymptomatic
- PE: dyspnea, pleuritic chest pain, tachypnea, hemoptysis, cyanosis, hypoxia, fever
- presence of risk factors and family history of venous thromboembolic disease
- clinical signs/symptoms are unreliable for diagnosis and exclusion of DVT/PE; investigation often needed (see Figures 12 and Figure 13)
- calculate the PERC score to assess the need for PE work-up before assessing the likelihood of a PE (Well's criteria)

Investigations (Figures 12-14)

- ECG and CXR are useful to look for other causes (e.g. ACS, pneumonia)
- D-dimer is only useful if it is negative in low risk patients
- Ultrasound has high sensitivity and specificity for proximal clot but only 73% sensitivity for DVT below the knee
- CT angiography has high sensitivity and specificity for PE, may also suggest other etiology
- V/Q scan useful when CT angio not available, or patient unable to tolerate IV contrast (e.g. renal failure, allergy)

Management of DVT/PE

- LMWH unless patient also has renal failure
 - dalteparin 200 IU/kg SC q24h or enoxaparin 1.5 mg/kg SC q24h
- warfarin started at same time as LMWH (5 mg PO daily initially)
- LMWH discontinued when INR has been therapeutic (2-3) for 2 consecutive days
 - early ambulation with analgesia is safe if appropriately anticoagulated
- IVC filter or surgical thrombectomy considered if anticoagulation is contraindicated
- consider thrombolysis if extensive DVT or PE causing hemodynamic compromise
 - often can be treated as outpatient, may require analgesia for chest pain (narcotic or NSAID)
- admit if hemodynamically unstable, require supplemental O₂, major comorbidities, lack of sufficient social supports, unable to ambulate, need invasive therapy
- long term anticoagulation
 - if reversible risk factor: 3-6 months of warfarin
 - idiopathic VTE: may need longer term warfarin (5 yrs or more)

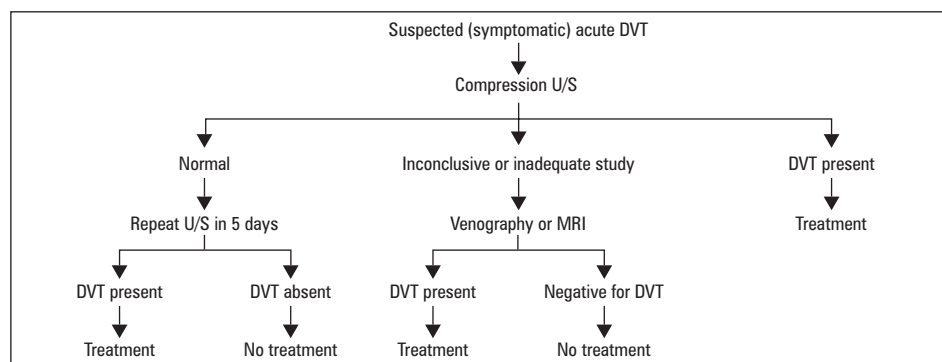

Figure 12. Approach to Suspected DVT

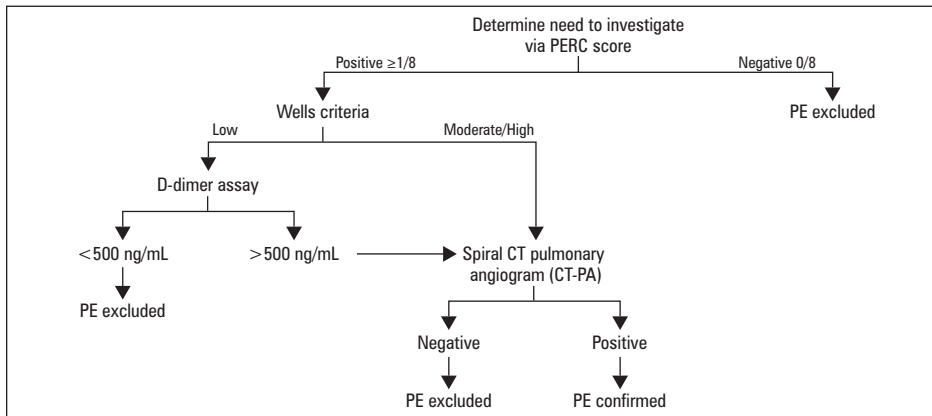

Figure 13. Approach to Suspected PE

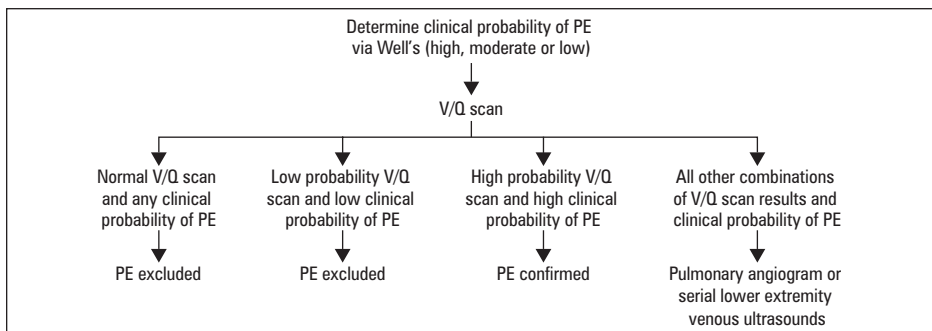

Figure 14. V/Q-Based Algorithm for Suspected PE

Clinical Criteria to Prevent Unnecessary Diagnostic Testing in Emergency Department Patients with Suspected Pulmonary Embolism

J Thromb Haemost 2004; 2(8):1247-55.
Purpose: To develop pulmonary embolism (PE) rule-out criteria (PERC) that can be used at the bedside, and prevents overtesting for PERC. Also, to prevent over-testing for PE, which includes the D-dimer test that frequently results in false positives.

Study: 21 variables were collected prospectively from 3148 ER patients evaluated for possible PE to develop rule-out criteria. The application of the developed rules was investigated in 1427 low-risk patients and 382 very-low risk patients.

Results: Eight variables were included in a block rule (Age <50 years, pulse <100 bpm, SaO₂ >94%, no unilateral leg swelling, no hemoptysis, no recent trauma or surgery, no prior PE or DVT, no hormone use) and a negative score was used to rule-out PE. In low-risk and very low-risk patients, the rule had a sensitivity of 96 and 100%, respectively and a specificity of 27 and 15%, respectively.

Summary: D-dimer testing for PE may not be favourable if all eight factors in the PERC are negative.

Diabetic Emergencies

- see also Endocrinology, E11

Diabetic Ketoacidosis (DKA)

- severe insulin deficiency resulting in hyperglycemia (11-55 mmol/L), dehydration and electrolyte abnormalities
- history and physical examination – often young, type 1 DM, may be first presentation of undiagnosed DM (may occur in small percentage of type 2 patients)
 - early symptoms: polyuria, polydipsia, malaise
 - late signs and symptoms
 - ♦ anorexia, nausea, vomiting, dyspnea (often due to acidosis), fatigue
 - ♦ abdominal pain
 - ♦ drowsiness, stupor, coma
 - ♦ Kussmaul's respiration
 - ♦ fruity acetone breath
- investigations
 - CBC, glucose, electrolytes, BUN/creatinine, Ca, Mg, phosphate, urine glucose and ketones
 - ABG
 - ECG (MI possible precipitant; electrolyte disturbances may predispose to arrhythmia)
- management
 - rehydration
 - ♦ bolus of NS, then high rate NS infusion (but beware of overhydration and cerebral edema, especially in pediatric patients)
 - potassium
 - ♦ essential to avoid hypokalemia: replace KCl (20 mEq/L if adequate renal function and initial K <5.5 mmol/L)
 - ♦ use cardiac monitoring if potassium levels normal or low
 - insulin
 - ♦ critical, as this is the only way to turn off gluconeogenesis/ketosis
 - ♦ do not give insulin if K <3.3 mmol/L
 - ♦ initial bolus of 5-10 U short-acting/regular insulin (or 0.2 U/kg) IV in adults (controversial – may just start with infusion)
 - ♦ followed by continuous infusion at 5-10 U (or 0.1 U/kg) per hour
 - ♦ add D5W when blood glucose <15 mM to prevent hypoglycemia
 - bicarbonate is not given unless patient is at risk of death or shock (typically pH <7.0)

Precipitating Factors in DKA

The 5 "I"s

Infection
 Ischemia
 Infarction
 Intoxication
 Insulin missed

4 criteria for DKA Dx: hyperglycemia, metabolic acidosis, hyperketonemia, ketonuria.

Hyperosmolar Hyperglycemic State (HHS)

- state of extreme hyperglycemia (44-133.2 mmol/L) due to relative insulin deficiency, increased counter-regulatory hormones, gluconeogenesis, and dehydration (due to osmotic diuresis) in type 2 DM, high mortality (approaches 50% even with optimal management)
- history and physical examination
 - mental disturbances, coma, delirium, seizures
 - polyuria
 - nausea, vomiting
- investigations
 - CBC, electrolytes, creatinine, BUN, glucose, Mg, phosphate, urine glucose and ketones
 - ABG
 - ECG
- management
 - rehydration with NS (total water deficit estimated at average 100 cc/kg body weight)
 - O₂ and cardiac monitoring, frequent electrolytes and glucose monitoring
 - insulin as required
 - identify and treat cause

Cerebral edema may occur if hyperosmolality treated too aggressively.

Hypoglycemia

- very common ED presentation
- management focus
 - treatment of hypoglycemia
 - investigation of cause (most often due to exogenous insulin, alcohol, sulfonylureas)
- history and physical examination
 - last meal, known diabetes, prior similar episodes, drug therapy and compliance
 - liver/renal/endocrine/neoplastic disease
 - depression, alcohol or drug use
- management
 - IV access and rapid BG
 - D50W 50 mL IV push, glucose PO if mental status permits
 - if IV access not possible, glucagon 1-2 mg IM, repeat x 1 in 10-20 min
 - O₂, cardiac, frequent BG monitoring
 - thiamine 100 mg IM
 - full meal as soon as mental status permits
 - if episode due to long acting insulin, or sulfonylureas, watch for prolonged hypoglycemia due to long t_{1/2} (may require admission for monitoring)
 - search for cause

**Drugs Inducing Hypoglycemia**

Insulin	Sulfa abx
Sulfonylureas	Cotrimazole
Ethanol	Ampicillin
Salicylates	Tetracycline
Acetaminophen	Amphetamines
NSAIDs	Cocaine
β-adrenergic agonists	Pyridoxine
Lithium	ACE-I
Calcium	Theophylline
MAOI	Quinine
Coumadin	

Electrolyte Disturbances

- see [Nephrology](#) and [Endocrinology](#)

Table 15. Electrolyte Disturbances

Electrolyte Disturbance	Common Causes	Symptoms	Treatment	Special Considerations
Hypernatremia	Inadequate H ₂ O intake (elderly/disabled) or inappropriate excretion of H ₂ O (diuretics, Li, DI)	Lethargy, weakness, irritability, and edema. Seizures and coma occur with severe elevations of Na levels (>158 mmol/L)	Salt restrict and give free water	No more than 12 mmol/L in 24 hrs drop in Na (0.5 mmol/L/hr) due to risk of cerebral edema, seizures, death
Hyponatremia	Hypo-osmolar (dilutional e.g. CHF, cirrhosis, ascites) and hyper-osmolar (usually glucose)	Acute: Neurologic symptoms 2° to cerebral edema, h/a, decreased LOC, depressed reflexes	Water restrict Acute: correct rapidly 3% NaCl 1-2 cc/kg/h Chronic: IV NS + furosemide	Limit total rise to 8 mmol/L in 24 hrs (0.5 mmol/L/hr maximum) as patients are at risk of central pontine myelinolysis
Hyperkalemia	Rhabdomyolysis, insulin deficiency, metabolic acidosis	Nausea, palpitations, muscle stiffness, areflexia	Protect heart: Ca gluconate Shift K into cells: Insulin R, NaHCO ₃ , Ventolin	ECG: Peaked/Narrow T wave, decreased P wave, prolonged PR interval, widening of QRS, AV block, V fib
Hypokalemia	Metabolic alkalosis, insulin, diuretics, anorexia Ventolin	Nausea, vomiting, fatigue, muscle cramps, constipation	K-Dur®, K sparing diuretics, IV solutions with 20-40 mEq KCl per liter over 3-4 hours	ECG: U waves most important, flattened/inverted T waves, prolonged QT, depressed ST May need to restore Mg
Hypercalcemia	Hyper-PTH and malignancy account for approx. 90% of cases	Multisystem including CVS, GI (groans), renal (stones), rheumatological, MSK (bones), psychiatric (moans)	Isotonic saline + lasix if hypervolemic Bisphosphonates, dialysis, chelation (EDTA or oral phosphate)	Patients with more severe or symptomatic hypercalcemia are usually dehydrated and require saline hydration as initial therapy
Hypocalcemia	Iatrogenic, low Mg, liver dysfunction, 1° hypo-PTH	Laryngospasm, hyperreflexia, parasthesia, tetany, Chvostek's and Trousseau's sign	Acute (ionized Ca <0.7 mM) requires immediate treatment: IV calcium gluconate 1-2 g in 10-20 mins followed by slow infusion	Prolonged QT interval can arise leading to arrhythmia as can upper airway obstruction

Hypertensive Emergencies

Hypertensive Emergency (Hypertensive Crisis)

- definition: acute elevation of systolic and diastolic BP (sBP >200, dBP >120) and associated acute end-organ damage (CNS, renal, CVS, haem, pregnancy related)
 - hypertensive encephalopathy: cerebral hyperperfusion due to blood pressure in excess of the capacity for cerebral autoregulation
 - signs and symptoms: headache, nausea, vomiting, mental status changes (lethargy to coma), fundoscopic changes, over hours can lead to coma and death
 - acute renal failure: can be either the cause or effect of a hypertensive emergency
 - diagnosis: proteinuria, RBCs and RBC casts in urine, elevated BUN and creatinine
 - treatment: IV calcium channel blockers, \pm emergent ultrafiltration
 - cardiovascular: MI, CHF, thoracic aortic dissection
 - left ventricular failure (LVF): decreased LV function due to increased afterload, increased oxygen demand and decreased coronary blood flow
 - signs and symptoms: chest pain, SOB
 - treatment: avoid diazoxide, hydralazine, minoxidil as these drugs increase oxygen demand
 - thoracic aortic dissection (see Cardiology, C48)

Pregnancy Induced Hypertension (PIH) see Obstetrics, OB14

- watch for HTN, abdominal pain with severe nausea and vomiting, seizures, proteinuria, thrombocytopenia, increased AST, clonus, and hyper-reflexia
 - initial treatment: lower BP, check reflexes, consider MgSO_4 if at risk for developing eclampsia, and assess risk to mother and fetus (e.g. deliver)
 - antihypertensives: hydralazine 5mg doses in 15 min intervals when dBP >105 or sBP >160, until dBP 90-100; consider IV labetalol as an alternative

Catecholamine-Induced Hypertensive Emergencies

- etiology: discontinuation of short-acting sympathetic blocker (e.g. clonidine, propranolol), pheochromocytoma, sympathomimetic drugs (cocaine, amphetamines, phencyclidine), MAOI in combination with sympathomimetics or tyramine-containing foods (cheese, red wine)
- treatment: immediate goal of IV therapy is to reduce the mean arterial pressure (MAP) by 25% in 30-60 min (5-10 min for aortic dissection) then a gradual reduction in MAP over the next 6 hrs to 160/100
 - BP should NOT be lowered rapidly in patients with major cerebrovascular event
 - decreasing BP too fast may extend or worsen stroke
 - if dBP >120, aim to reduce dBP by 20% in the first 24 hrs
 - treatment may be initiated in the ED followed by prompt admission to ICU for continuous BP monitoring
 - re-administer sympathetic blocker if due to withdrawal (e.g. clonidine, propranolol)

Hypertensive Urgency

- definition: severely elevated blood pressure (usually sBP >180, dBP >115) with no evidence of end-organ damage
- most commonly due to non-adherence with medications
- treatment: gradually reduce pressure over 24-48 hours to a level appropriate for the patient
- goal is to differentiate hypertensive emergencies from hypertensive urgencies

History and Physical Examination

- prior hypertensive crises
- antihypertensive medications prescribed, adherence, and BP control
- MAOIs, substance use, use of stimulants or withdrawal from sedatives including EtOH
- blood pressure measurement in all limbs
- fundoscopic exam (hemorrhages, papilledema, etc.), gross motor examination

Investigations

- CBC, electrolytes, BUN, creatinine, urinalysis
- peripheral blood smear – to detect microangiopathic hemolytic anemia
- CXR – if SOB or chest pain
- ECG, troponins, CK – if chest pain
- CT head – if neurological findings or severe headache

Treatment of Hypertensive Emergencies

- see Table 16

Signs of Fluid Depletion

Increased heart rate
Postural changes in vital signs
Decreased urine output (normal: 0.5 cc/kg/hr)
Hypertensive
Decreased skin turgor
Sunken eyes
Dry mucous membranes
Decreased capillary refill

HELLP Syndrome (seen only in preeclampsia/eclampsia)
Hemolytic anemia
Elevated Liver enzymes
Low Platelet count

Catecholamine Induced Hypertensive Emergencies

Avoid use of non-selective β -blockers as they inhibit β -mediated vasodilation and leave α -adrenergic vasoconstriction unopposed.

Signs/Symptoms of CNS Hypertensive Emergency

N/V
Seizure
Headache or altered mental status
Cushing response

Evidence of End-Organ Damage

CNS: headache, focal neurological signs, seizures
CVS: angina, CHF, back pain (aortic dissection)
Renal: hematuria, oliguria
Eyes: papilledema, retinal hemorrhages

With CNS manifestations of severe hypertension, it is often difficult to differentiate causal relationships [i.e. hypertension could be secondary to primary cerebral event (Cushing effect)].

Most commonly used agents for hypertensive crisis are labetalol and nitroprusside.

Drugs that Increase Adrenergic Stimulation
MAOIs
TCAs
Amphetamines
Cocaine

Table 16. Most Commonly Used Agents for the Treatment of Hypertensive Crisis

Drug	Dosage	Onset of Action	Duration of Action	Adverse Effects*	Special Indications
VASODILATORS					
Sodium Nitroprusside (vascular smooth muscle dilator) 1st line	0.25-10 µg/kg/min	Immediate	3-5 min	N/V, muscle twitching, sweating, cyanide intoxication, coronary steal syndrome	Most hypertensive emergencies (esp CHF, aortic dissection) Use in combination with β-blockers (e.g. esmolol) in aortic dissection Caution with high ICP and azotemia
Nicardipine (CCB)	2 mg IV bolus, then 4 mg/kg/hr IV	15-30 min	40 min	Tachycardia, headache, flushing, local phlebitis (e.g. encephalopathy, RF, eclampsia, sympathetic crisis)	Most hypertensive emergencies Caution with acute CHF
Fenoldopam Mesylate (dopamine receptor antagonist)	0.05-0.1 µmg/kg/min IV	<5 min	8-10 min	Tachycardia, headache, nausea, flushing (e.g. acute RF)	Most hypertensive emergencies Caution with glaucoma
Enalapril (ACEI)	0.625-1.25 mg IV q6h	15-30 min	12-24 hr	Theoretical fall in pressure in high renin states not seen in studies	Acute LV failure Avoid in acute MI, pregnancy, acute RF
Nitroglycerin	5-20 µg/min IV	1-2 min	3-5 min	Hypotension, bradycardia, headache, lightheadedness, dizziness	MI/Pulmonary edema
Hydralazine	5-10 mg IV/IM q20min (max 20 mg)	5-20 min	2-6 hrs	Dizziness, drowsiness, headache, tachycardia, Na retention	Eclampsia
ADRENERGIC INHIBITORS					
Labetalol	20 mg IV bolus q10 min or 0.5-2 mg/min	5-10 min	3-6 hr	Vomiting, scalp tingling, burning in throat, dizziness, nausea, heart block, orthostatic hypotension	Most hypertensive emergencies (esp. eclampsia) Avoid in acute CHF, HB > 1st degree
Esmolol	250-500 µg/kg/min 1 min, then 50 µg/kg/min for 4 min; repeat	1-2 min	10-20 min	Hypotension, nausea, bronchospasm	Aortic dissection, acute MI SVT dysrhythmias, perioperative HTN Avoid in acute CHF, HB > 1st degree
Phentolamine	5-15 mg q5-15 min	1-2 min	3-10 min	Tachycardia, headache, flushing	Catecholamine excess (e.g. pheo)

*Hypotension may occur with all of these agents

If patient presents within 4.5 hours of onset of disabling neurological deficits greater than 60 minutes with no signs of resolution, they may be candidate for thrombolysis. Do brief assessment and order stat CT head.

Exclusion Criteria for tPA:

Suspected subarachnoid hemorrhage
Previous intracranial hemorrhage
Cerebral infarct or severe head injury within the past 3 months
Recent pericarditis
Major surgery within the past 14 days
GI or urinary hemorrhage within the past 21 days
Recent lumbar puncture or arterial puncture at noncompressible site
Patient is pregnant
BP = 185 mmHg systolic, or = 110 mmHg diastolic
Bleeding diathesis
Prolonged PTT (more than 40 seconds) or INR > 1.4
Platelet count < 100,000
Blood glucose < 2.8 or > 22 mmol/L
Intracranial hemorrhage on CT/or large volume infarct
Seizure at onset causing deficit
Previously ADL dependent (clinical judgment)

Stroke

- see Neurology, N44
- can be ischemic (80% of all strokes) or hemorrhagic

History

- consider acute stroke if acute neurological deficit (focal or global) or altered LOC
- more likely to be hemorrhagic if: nausea, vomiting, headache, change in LOC, seizure
- common symptoms of stroke: abrupt onset of hemiparesis/monoparesis, visual loss/field deficits, diplopia, dysarthria, ataxia, vertigo, aphasia, sudden decrease in LOC
- determine time of symptom onset for consideration of thrombolytic therapy
- DDx includes hypoglycemia, Todds paralysis, peripheral nerve injury, Bell's palsy, tumour

Physical Examination

- vitals
- if decreased LOC: assess for ability to protect airway
- rule out trauma, infection, meningeal irritation
- search for cardiovascular causes of stroke
 - ocular fundi (retinopathy, emboli, hemorrhage) and pupils
 - CVS (murmurs, gallops, AFib)
 - PVS (auscultate for carotid bruits)

- neuro
 - mental status, LOC, cranial nerves, motor function, sensory function, cerebellar function, gait, deep tendon reflexes
 - confirm presence of stroke syndrome, and distinguish from stroke mimics (seizure, systemic infection, brain tumour, positional vertigo, Bell's palsy)
 - establish neurological baseline should patient improve/deteriorate

Table 17. Stroke Syndromes

Region of Stroke	Stroke Syndrome
Anterior Cerebral Artery	Primarily frontal lobe function affected Altered mental status, impaired judgment, contralateral lower extremity weakness and hypoesthesia, gait apraxia
Middle Cerebral Artery	Contralateral hemiparesis (arm and face weakness > leg weakness) and hypoesthesia, ipsilateral hemianopsia, gaze preference to side of lesion ± agnosia, receptive/expressive aphasia
Posterior Cerebral Artery	Affects vision and thought Homonymous hemianopsia, cortical blindness, visual agnosia, altered mental status, impaired memory
Vertebrobasilar Artery	Wide variety of CN, cerebellar and brainstem deficits: vertigo, nystagmus, diplopia, visual field deficits, dysphagia, dysarthria, facial hypoesthesia, syncope, ataxia Loss of pain and temperature sensation ipsilateral face and contralateral body

Investigations

- CBC, electrolytes, blood glucose, coagulation studies, ± cardiac biomarkers, ± toxicology screen
- non-contrast CT head: look for hemorrhage, ischemia
- ECG ± echocardiogram: rule out atrial fibrillation, acute MI as source of emboli
 - other imaging: carotid dopplers, CTA, MRA as appropriate

Management

- quickly determine if patient is eligible for thrombolysis (need acute onset less than 4.5 hours from drug administration time AND compatible physical findings AND normal CT with no bleed) – not much time to do all of this (often requires designated stroke team)
- ABCs with RSI if GCS ≤8, rapidly decreasing GCS, or inadequate airway protection reflexes
- IV ± cardiac monitoring
 - judge fluid rate carefully to avoid overhydration (cerebral edema) as well as underhydration (underperfusion of the ischemic penumbra)
- BP control: only treat severe hypertension (sBP >200, dBP >120, mean arterial BP >140) or hypertension associated with hemorrhagic stroke transformation, cardiac ischemia, aortic dissection, or renal damage; use IV nitroprusside or labetalol
- cerebral edema control: hyperventilation, mannitol to decrease ICP if necessary
- consult neurosurgery, neurology as indicated

Medications

- acute ischemic stroke: thrombolytics (rt-PA, e.g. alteplase) if within 3 hours of symptom onset with no evidence of hemorrhage on CT scan
- antiplatelet agents: prevent recurrent stroke or stroke after TIAs, e.g. aspirin (1st-line); clopidogrel, ticlopidine (2nd-line)

**Differentiation of UMN Disease versus LMN Disease**

Category	UMN Disease	LMN Disease
Muscular deficit	Muscle groups	Individual muscles
Reflexes	Increased	Decreased/absent
Tone	Increased	Decreased
Fasciculations	Absent	Present
Atrophy	Absent/minimal	Present

**7 Causes of Emboli from the Heart**

Atrial Fib
MI
Endocarditis
Valvular disease
Dilated cardiomyopathy
Left heart myxoma
Prosthetic Valves

**Causes of Acute Ataxia****UNABLE TO STAND**

Underlying weakness (mimic ataxia)
Nutritional neuropathy (vitamin B₁₂ deficiency)
Arteritis/vasculitis
Basilar migraine
Labyrinthitis/vestibular neuronitis
Encephalitis/infection

Trauma (post-concussive)
Other (rare genetic or metabolic disease)

Stroke (ischemia or hemorrhage)
Toxins (drugs, toluene, mercury)
Alcohol
Neoplasm/paraneoplastic syndrome
Demyelination (Miller Fisher, Guillain Barré, MS)

Gynecologic/Urologic Emergencies

Vaginal Bleed

- see Gynecology, GY6 and Obstetrics, OB20

Etiology

- pregnant patient
 - 1st/2nd trimester pregnancy: ectopic pregnancy, abortion (threatened, incomplete, complete, missed, inevitable, septic), molar pregnancy
 - 2nd/3rd trimester pregnancy: placenta previa, placental abruption, premature rupture of membranes, preterm labour
 - either: trauma, bleeding cervical polyp
- postpartum
 - postpartum hemorrhage, uterine inversion, retained placental tissue, endometritis
- non-pregnant patients
 - dysfunctional uterine bleeding, uterine fibroids, pelvic tumours, trauma, endometriosis, PID, exogenous hormones

Vaginal bleeding can be life threatening. Always start with ABCs and ensure your patient is stable.

History

- menstrual history, sexual activity, contraception, history of PID
- pregnancy details
- determine amount of blood
- urinary, GI symptoms

Physical Examination

- look for signs of hypovolemia
- pelvic examination – NOT if suspected placenta previa (ultrasound first)
- speculum exam
 - if pregnant use sterile speculum
- bimanual examination
 - if pregnant use sterile gloves
 - if patient is near term with possible rupture of membranes and without other indications defer bimanual examination (infection risk)

Investigations

- β -hCG test for all patients with child-bearing potential
- CBC, blood and Rh type, quantitative β -hCG, PTT, INR
- type and cross if significant blood loss
- 1st/2nd trimester/non-pregnant
 - ultrasound (U/S) – intrauterine pregnancy, ectopic pregnancy, traumatic injury, foreign body
 - must correlate U/S findings with β -hCG if U/S is non-diagnostic (transvaginal ultrasound will not see gestation in uterus if β -hCG <1200 – must repeat)
- 2nd/3rd trimester pregnancy
 - U/S if no fetal heart tones, no documented intrauterine pregnancy or unknown lie of placenta
 - non-stress test to assess fetal well-being during work up of mother
 - DIC panel if placental abruption – CBC, PTT, INR, fibrinogen
- postpartum
 - U/S for retained products
 - β -hCG if concerned about retained tissue

Management

- ABCs
- pulse oximeter and cardiac monitors if unstable
- Rh immune globulin for vaginal bleeding in pregnancy and Rh-negative mother
- 1st/2nd trimester pregnancy
 - ectopic pregnancy: definitive treatment with surgery or methotrexate
 - intrauterine pregnancy, no concerns of coexistent ectopic: discharge patient with obstetrics follow-up
 - U/S indeterminate or β -hCG >1000-2000 IU: further work-up and/or gynecology consult
 - abortions: if complete, discharge if stable; for all others, acquire gynecology consult
- 2nd/3rd trimester pregnancy
 - placenta previa or placental abruption: obstetrics consult for possible admission
- postpartum
 - uterine inversion: replace uterus immediately, may require operative management
 - postpartum hemorrhage: extraction of placenta if retained, hysterectomy if uncontrolled bleeding
 - retained tissue: D&C
 - endometritis: IV antibiotics
- non-pregnant
 - dysfunctional uterine bleeding (prolonged or heavy flow \pm breakthrough bleeding and without ovulation, a diagnosis of exclusion)
 - ♦ <35-40 years of age: Provera® 10 mg PO x 10 days, warn patient of a withdrawal bleed, discharge if stable
 - ♦ if unstable, admit for IV hormonal therapy, possible D&C
 - ♦ >35-40 years of age: uterine sampling necessary prior to initiation of hormonal treatment to rule out endometrial cancer, U/S for any masses felt on exam
 - structural abnormalities: fibroids or uterine tumours may require excision for diagnosis/treatment, U/S for workup of other pelvic masses, Pap smear/biopsy for cervical lesions

Disposition

- the decision to admit or discharge should be based on the stability of the patient, as well as the nature of the underlying cause; consult gynecology for admitted patients
- if patient can be safely discharged, ensure follow up with family physician or gynecologist
 - instruct patient to return to emergency for increased bleeding, presyncope

Need β -hCG ≥ 1200 to see interuterine changes on transvaginal U/S.

Classifying miscarriage (abortion):

Missed – non-viable intrauterine pregnancy
Threatened – viable intrauterine pregnancy with os closed
Inevitable – os closed, no products of conception passed
Incomplete – products of conception partially expelled
Complete – products of conception completely expelled
Septic – any of above with presence of infection (usually incomplete)
Recurrent – >3 spontaneous abortions (recurrent pregnancy loss)

Vaginal bleeding (and its underlying causes) can be a very emotionally taxing presentation for patients. Ensure appropriate support is provided.

Pregnant Patient in the ER

Table 18. Complications of Pregnancy

Trimester	Fetal	Maternal
First 1-14 wks	Pregnancy failure • Spontaneous abortion • Fetal demise • Gestational trophoblastic disease	Ectopic pregnancy Anemia Hyperemesis gravidarum UTI/pyelonephritis
Second 15-27 wks	Disorders of fetal growth • IUGR • Oligo/polyhydramnios	Gestational diabetes mellitus Rh incompatibility UTI/pyelonephritis
Third 28-40 wks	Vasa previa	Preterm labour/PPROM Preeclampsia/eclampsia Placenta previa Placental abruption Uterine rupture DVT

Nephrolithiasis (Renal Colic)

- see Urology, U15

Epidemiology and Risk Factors

- 10% of population (twice as common in males)
- recurrence 50% at 5 yrs
- peak incidence 30-50 years of age
- 75% of stones <5 mm pass spontaneously within 2 weeks, larger stones may require consultation

Clinical Features

- urinary obstruction → upstream distention of ureter or collecting system → severe colicky pain
- may complain of pain at flank, groin, testes, or tip of penis
- writhing, never comfortable, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- fever, chills, rigors in secondary pyelonephritis

Differential Diagnosis of Renal Colic

- acute ureteric obstruction (other causes)
 - UPJ obstruction
 - sloughed papillae
 - clot colic from gross hematuria
 - extrinsic (e.g. tumour)
- acute abdomen – biliary, bowel, pancreas, AAA
- gynecological – ectopic pregnancy, torsion/rupture of ovarian cyst
- pyelonephritis (fever, chills, pyuria, vomiting)
- radiculitis (L1) – herpes zoster, nerve root compression

Investigations

- screening labs
 - CBC → elevated WBC in presence of fever suggests infection
 - electrolytes, Cr, BUN → to assess renal function
 - urinalysis: R&M (WBCs, RBCs, crystals), C&S
- imaging
 - non-contrast spiral CT is the study of choice
 - abdominal ultrasound may demonstrate stone or hydronephrosis
- strain all urine → stone analysis

Management

- analgesics, antiemetics, IV fluids
- urology consult may be indicated, especially if stone >5 mm, or if patient has signs of obstruction or infection
- α-blocker helpful to increase stone passage in select cases

Disposition

- most patients can be discharged
- ensure patient is stable, has adequate analgesia, and is able to tolerate oral medications
- may advise hydration, calcium supplementation, and limitation of protein, sodium, oxalate and alcohol intake

Kidney Stones
 80% Ca
 10% Struvite
 10% Uric acid

Indications for Admission to Hospital

- Intractable pain
- Fever (suggests infection)
- Single kidney with ureteral obstruction
- Bilateral obstructing stones
- Intractable vomiting
- Compromised renal function

Ophthalmologic Emergencies

Ophthalmologic Foreign Body and Corneal Abrasion

- see also [Ophthalmology](#), OP17

ALWAYS assess visual acuity in both eyes when a patient presents to the ER with an ophthalmologic complaint.

Any etiology of red eyes may also present with blurred vision.

Other Ophthalmologic Emergencies
(See [Ophthalmology](#), OP5)

Infectious – Red eye (Table 19), endophthalmitis, orbital cellulitis
Trauma – retinal detachment, globe rupture, orbital blow-out fractures, chemical burns
Autoimmune – Giant cell arteritis

Contraindications to Pupil Dilation

- Shallow anterior chamber
- Iris-supported lens implant
- Potential neurological abnormality requiring pupillary evaluation
- Caution with CV disease – mydriatics can cause tachycardia

History

- patient may complain of pain, tearing, itching, redness, photophobia, foreign body sensation
- elicit history of potential trauma to eye
- mechanism of foreign body insertion – if high velocity injury suspected (welding, metal grinding, metal striking metal), must obtain orbital x-rays or ultrasound to exclude presence of intraocular metallic foreign body
- see Table 19 for important considerations of red eye in the emergency department

Table 19. Differential Diagnosis of Red Eye in the Emergency Department

Symptom	Possible Serious Etiology
Light Sensitivity	Iritis, keratitis, abrasion, ulcer
Unilateral	Above + herpes simplex, acute angle closure glaucoma
Significant pain	Above + scleritis
White spot on cornea	Corneal ulcer
Blurred vision	All of the above
Non-reactive pupil	Acute glaucoma, iritis
Copious discharge	Gonococcal conjunctivitis

Physical Examination

- visual acuity in both eyes with best corrected vision
- pupils, extraocular movement, external ocular structures
- fundoscopy
- tonometry – measurement of intraocular pressure (with Tonopen)
 - normal pressure: 10-20 mmHg, glaucoma associated with increased pressures
- slit lamp exam:
 - start with unaffected eye, perform a systematic examination: lids, lashes, lacrimal apparatus, conjunctiva, sclera, cornea, anterior chamber, iris, lens, vitreous
 - proparacaine anaesthetic drops may ease examination
 - look for rust ring with metallic foreign body, corneal edema, anterior chamber cells/flare
 - may use fluorescein dye which stains de-epithelialized cornea green when viewing with cobalt blue filter

Management

- copious irrigation with saline for any foreign body
- remove foreign body under slit lamp exam with cotton swab or sterile needle
- antibiotic drops qid until healed
- patching may not improve healing or comfort – do not patch contact lens wearers
- limit use of topical anesthetic to examination only
- consider tetanus prophylaxis
- ophthalmology consult if globe penetration suspected

Initial Management of other Ophthalmologic Emergencies

- ruptured globe – stabilize any foreign body, shield eye with no pressure, elevate head of bed to 30°, tetanus prophylaxis, IV antibiotics, NPO, analgesic, antiemetic, sedation prn
- retinal artery occlusion – globe massage, paper bag breathing, carbogen inhalation (95% oxygen, 5% carbon dioxide)
- chemical burn – immediate copious irrigation, may consider topical anaesthetic drops to facilitate irrigation
- acute angle-closure glaucoma – IV or PO acetazolamide, topical pilocarpine and timolol
- preseptal cellulitis (2° to superficial trauma) – topical or systemic Abx
- orbital cellulitis (2° to sinusitis) – admit, IV antibiotics, blood cultures, CT

Disposition

- most patients can be discharged with outpatient ophthalmology follow-up
- admit patients requiring emergent ophthalmologic procedures or IV antibiotics

Dermatologic Emergencies

Life Threatening Dermatoses

Rash Characteristics

- **DIFFUSE RASH**
 - **staphylococcal scalded skin syndrome (SSSS)**
 - ♦ caused by an exotoxin from infecting strain of coagulase-positive *S. aureus*
 - ♦ mostly occurs in children
 - ♦ prodrome: fever, irritability, malaise and skin tenderness
 - ♦ sudden onset of diffuse erythema: skin is red, warm, and very tender
 - ♦ flaccid bullae that are difficult to see, then desquamate in large sheets
 - ♦ Nikolsky's sign: gentle lateral stroking of skin causes epidermis to separate
 - **toxic epidermal necrolysis (TEN)**
 - ♦ see Dermatology, D22
 - ♦ caused by drugs (e.g. phenytoin, sulfas, penicillins and NSAIDs), bone marrow transplantation, blood product transfusions
 - ♦ usually occurs in adults
 - ♦ diffuse erythema followed by necrosis
 - ♦ severe mucous membrane blistering
 - ♦ entire epidermis desquamation
 - ♦ high mortality (>50%)
 - **toxic shock syndrome (TSS)**
 - ♦ see Infectious Diseases, ID27
 - ♦ caused by superantigen from *S. aureus* or GAS activating T-cell and cytokines
 - ♦ patient often presents with onset of shock and multi-organ failure, fever
 - ♦ diffuse erythematous macular rash
 - ♦ at least 3 organ systems involved: CNS, respiratory, GI, muscular, mucous membranes, renal, liver, hematologic, skin (necrotizing fasciitis, gangrene)
- **VESICOBULLOUS LESIONS**
 - **erythema multiforme (EM)**
 - ♦ see Dermatology, D22
 - ♦ immunologic reaction to herpes simplex
 - ♦ viral prodrome 1-14 days before rash
 - ♦ "target lesion": central gray bulla or wheal surrounded by concentric rings of erythema and normal skin
 - **Stevens-Johnson syndrome (SJS)**
 - ♦ see Dermatology, D22
 - ♦ related to drugs such as antiepileptics and biologic agents, e.g. infliximab
 - ♦ EM with constitutional symptoms and mucous membrane involvement (milder mucous membrane involvement than TEN)
- **DISCRETE LESIONS**
 - **pyoderma gangrenosum**
 - ♦ often associated with immunocompromised patients (HIV, leukemia or lymphoma) with Gram-negative sepsis
 - ♦ often occurs in arms, hands, feet, or perineal region
 - ♦ usually begins as painless macule/vesicle → pustule/bulla on red/blue base → sloughing, leaving a gangrenous ulcer
 - **disseminated gonococcal infection (DGI)**
 - ♦ see Dermatology, D32
 - ♦ fever, skin lesions (pustules/vesicles on erythematous base ~5 mm in diameter), arthritis (joint swelling and tenderness), septic arthritis (in larger joints, e.g. knees, ankles and elbows)
 - ♦ most commonly in gonococcus positive women during menstruation or pregnancy
 - ♦ skin lesions usually appear in extremities and resolve quickly (<7 days)
 - **meningococcemia**
 - ♦ flu-like symptoms of headache, myalgia, nausea and vomiting
 - ♦ petechial, macular or maculopapular lesions with gray vesicular centres
 - ♦ usually a few millimeters in size but may become confluent and hemorrhagic
 - ♦ usually appear in extremities but may appear anywhere
 - ♦ look for signs of meningeal irritation: Brudzinski, Kernig, nuchal rigidity, jolt accentuation

History and Physical Examination

- determine onset, course, location of skin lesions
- fever, joint pain
- associated symptoms: CNS, resp, GU, GI, renal, liver, mucous membranes
- medication history
- vitals

Thorough dermatologic examinations are required; examination of asymptomatic skin may identify more lesions! Ensure adequate draping during dermatologic examinations.

Investigations

- immediate consultation if patient unstable
- CBC, electrolytes, creatinine, AST, ALT, ALP, blood culture, skin biopsy, serum immunoglobulin levels (serum IgE)

Management

- general: judicious IV fluids and electrolyte control, consider vasopressors if hypotensive, prevention of infection
- determine if admission and consult needed: dermatology or infectious diseases
- specific management is determined by etiology
 - SSSS, TSS, DGI and meningococemia
 - ♦ IV antibiotics
 - EM, SJS, and TEN
 - ♦ stop precipitating medication
 - ♦ fluids
 - ♦ symptomatic treatment: antihistamines, antacids, topical corticosteroids, systemic corticosteroids (controversial), prophylactic oral acyclovir, consider IVIG
 - ♦ TEN: debride necrotic tissue

Disposition

- most cases will require urgent care and hospitalization
- TEN: early transfer to burn centre improves outcome

Environmental Injuries

Heat Exhaustion and Heat Stroke

- predisposing factors: young persons who overexert themselves, older adults who cannot dissipate heat at rest (e.g. using anticholinergic drugs such as antihistamines or TCAs), and patients with schizophrenia who are using anticholinergic or neuroleptic medications

Heat Exhaustion (HE)

- clinical features relate to loss of circulating volume caused by exposure to heat stress
- “water depletion”: HE occurs if lost fluid not adequately replaced
- “salt depletion”: HE occurs when losses replaced with hypotonic fluid

Heat Stroke

- life-threatening emergency resulting from failure of normal compensatory heat-shedding mechanisms
- divided into classical and exertional subtypes (see Table 20)
- if patient does not respond relatively quickly to cooling treatments, consider other possible etiologies of hyperpyrexia (e.g. meningitis, thyroid storm, anticholinergic poisoning, delirium tremens, other infections)

Table 20. Heat Exhaustion vs. Heat Stroke

	Heat Exhaustion	Classical Heat Stroke	Exertional Heat Stroke
Clinical Features	<ul style="list-style-type: none"> • Non-specific malaise, headache, fatigue • Body temp <40.5°C (usually normal) • No coma or seizures • Dehydration (↑ HR, orthostatic hypotension) 	<ul style="list-style-type: none"> • Occurs in setting of high ambient temperatures (e.g. heat wave, poor ventilation) • Often patients are older, poor, and sedentary or immobile • Dry, hot skin • Temp usually >40.5°C • Altered mental status, seizures, delirium, coma • May have elevated AST, ALT 	<ul style="list-style-type: none"> • Occurs with high endogenous heat production (e.g. exercise) and overwhelmed homeostatic mechanisms • Patients often younger, more active • Skin often diaphoretic • Other features as for classical HS, but may also have DIC, acute renal failure, rhabdomyolysis, marked lactic acidosis
Treatment	<ul style="list-style-type: none"> • Rest in a cool environment • Normal saline IV if orthostatic hypotension; otherwise replace losses slowly PO 	<ul style="list-style-type: none"> • Cool down body temperature with water mist (e.g. spray bottle) and standing fans • Ice water immersion also effective; monitor body temp closely to avoid hypothermic overshoot • Secure airway because of risk of seizures and aspiration • Give fluid resuscitation if still hypotensive after above therapy • Avoid α-agonists (e.g. epinephrine) peripheral vasoconstriction and antipyretics (e.g. ASA) 	

Heat exhaustion (HE) may closely resemble heat stroke. HE may eventually progress to heat stroke. Therefore if diagnosis is uncertain treat as heat stroke.

Hypothermia and Cold Injuries

- predisposing factors: extremes of age, lack of housing, drug overdose, EtOH ingestion, trauma (incapacitating), cold water immersion, outdoor sports
- treatment based on: (a) re-warming and (b) supporting cardiorespiratory function
- complications: coagulopathy, acidosis, ventricular arrhythmias (VFib), asystole, volume and electrolyte depletion
- labs: CBC, electrolytes, ABG, serum glucose, creatinine/BUN, Mg, Ca, amylase, coagulation profile
- imaging: CXR (aspiration pneumonia, pulmonary edema are common)
- monitors: ECG, rectal thermistor, Foley catheter, NG tube, monitor metabolic status frequently

Table 21. Classification of Hypothermia

Class	Temp	Symptoms/Signs
Mild	32-34.9°C	Tachypnea, tachycardia, ataxia, dysarthria, shivering
Moderate	28-31.9°C	Loss of shivering, arrhythmias, Osborne (J) waves on ECG, decreased LOC, combative behaviour, muscle rigidity, dilated pupils
Severe	<28°C	Coma, hypotension, acidemia, ventricular fibrillation, asystole, flaccidity, apnea

Re-warming Options

- gentle fluid and electrolyte replacement in all (due to cold diuresis)
- Passive External Re-warming (PER)
 - suitable for most stable patients with core temperature >32.2°C
 - involves covering patient with insulating blanket; body generates heat and re-warms through metabolic process, shivering
- Active External Re-warming (AER)
 - involves use of warming blankets
 - beware “afterdrop” phenomenon (warming of extremities causes vasodilation and movement of cool pooled blood from extremities to core, resulting in a drop in core temperature → cardiac arrest)
 - safer when done in conjunction with active core re-warming
- Active Core Re-warming (ACR)
 - generally for patients with core temperature <32.2°C, and/or with cardiovascular instability
 - avoids “afterdrop” seen with AER alone
 - re-warm core by using
 - ♦ warmed humidified oxygen, IV fluids
 - ♦ peritoneal dialysis with warm fluids
 - ♦ gastric/colonic/pleural irrigation with warm fluids
 - ♦ external circulation (cardiopulmonary bypass machine) is most effective, fastest

Cardiac Arrest in the Hypothermic Patient

- do all procedures gently or may precipitate VFib
- check pulse and rhythm for at least 1 minute; may have profound bradycardia
- if any pulse at all (even very slow) do NOT do CPR
- if in VFib try to defibrillate up to max 3 shocks if core temperature <30°C
- intubate gently if required, ventilate with warmed, humidified O₂
- medications (vasopressors, antiarrhythmics) may not be effective at low temperatures
 - controversial; may try one dose
- focus of treatment is re-warming

FROSTBITE

Classification

- ice crystals form between cells
- classified according to depth – similar to burns (1st to 3rd degree)
- **1st degree**
 - symptoms: initial paresthesia, pruritus
 - signs: erythema, edema, hyperemia, no blisters
- **2nd degree**
 - symptoms: numbness
 - signs: blistering (clear), erythema, edema
- **3rd degree**
 - symptoms: pain, burning, throbbing (on thawing); may be painless if severe
 - signs: hemorrhagic blisters, skin necrosis, edema, no movement

Management

- treat for hypothermia: O₂, IV fluids, maintenance of body warmth
- remove wet and constrictive clothing

**Burn causes:**

Thermal (flame, scald)
Chemical
Radiation (UV, medical/therapeutic)
Electrical

**High Risk Factors for Infection**

- Puncture wounds
- Crush injuries
- Wounds greater than 12 hours old
- Hand or foot wounds, wounds near joints
- Immunocompromised patient
- Patient age greater than 50 years
- Prosthetic joints or valves (risk of endocarditis)

Use palm of the patient's hand to estimate 1% of BSA affected.

Anterior**Posterior**

Figure 15. Rule of 9's for Total Body Surface Area (BSA)

Intubate early if you suspect inhalation injury, as airway can become obstructed due to edema.

- immerse in 40-42°C agitated water for 10-30 minutes (very painful; administer adequate analgesia)
- clean injured area, leave injured region open to air
- consider aspiration/debridement of blisters (controversial)
- debride skin gently
- tetanus prophylaxis
- consider penicillin G as frost bite injury at high risk of infection
- surgical intervention may be required to release restrictive eschars
- never allow a thawed area to re-chill/freeze

Burns

- see Plastic Surgery, PL15

Physical Examination

- burn size
 - rule of nines (see Figure 15); does not include 1st degree burns
- burn depth
 - superficial: epidermis only (e.g. sunburn)
 - partial thickness: into superficial dermis deep or hair follicles, sweat glands
 - full thickness: all layers of the skin
 - deep: to fat, muscle, even bone

Management

- remove noxious agent/stop burning process
- establish airway if needed (indicated with burns >40% BSA or smoke inhalation injury)
- resuscitation for 2nd and 3rd degree burns (after initiation of 2 large bore IVs)
 - Parkland Formula: Ringer's lactate 4 cc/kg/%BSA burned; give half in first 8 hours, half in next 16 hours; maintenance fluids are also required if patient cannot tolerate PO hydration
 - urine output is best measure of resuscitation, should be 40-50 cc/hr or 0.5 cc/kg/hr; avoid diuretics
- pain relief – continuous morphine infusion with breakthrough bolus
- investigations: CBC, electrolytes, urinalysis, CXR, ECG, ABG, carboxyhemoglobin
- burn wound care – prevent infection, clean/debride with mild soap and water, sterile dressings
- escharotomy or fasciotomy for circumferential burns (chest, extremities)
- topical antibiotics, systemic antibiotics infrequently indicated
- tetanus prophylaxis if burn is deeper than superficial dermis

Disposition

- admit
 - 2nd degree burns to >10% BSA; any significant 3rd degree burns
 - 2nd degree on face, hands, feet, perineum or across major joints
 - electrical, chemical burns and inhalation injury
 - burn victims with underlying medical problems or immunosuppressed patients

Inhalation Injury

Etiology

- carbon monoxide (CO) poisoning
- direct thermal injury – limited to upper airway
- smoke causes bronchospasm and edema from particulate matter and toxic inhalants (tissue asphyxiates, pulmonary irritants, systemic toxins)

History and Physical

- risk factors: closed space fires, period of unconsciousness, noxious chemicals involved
- cherry red skin (unreliable, usually post-mortem finding)
- singed nasal hairs, soot on oral/nasal membranes, sooty sputum
- hoarseness, stridor, dyspnea
- decreased LOC, confusion
- PO₂ normal but O₂ sat low suggests CO poisoning

Investigations

- measure carboxyhemoglobin levels
- ABG
- CXR ± bronchoscopy

Management

- CO poisoning: 100% O₂ ± hyperbaric O₂ (controversial)
- direct thermal injury: humidified oxygen, early intubation, pulmonary toilet, bronchodilators

Bites

Mammalian Bites

- see [Plastic Surgery](#), PL6
- **history**
 - time and circumstances of bite, symptoms, allergies, tetanus immunization status, comorbid conditions, rabies risks, HIV/hepatitis risk (human bite)
 - high morbidity associated with clenched fist injuries (CFI), “fight bites”
- **physical examination**
 - assess type of wound: abrasion, laceration, puncture, crush injury
 - assess for direct tissue damage: skin, bone, tendon, neurovascular status
- **investigations**
 - if bony injury or infection suspected check for fracture and gas in tissue with x-rays
 - get skull films in children with scalp bite wounds, ± CT to rule out cranial perforation
- **initial management**
 - wound cleansing and copious irrigation as soon as possible
 - irrigate/debride puncture wounds if feasible, but not if sealed or very small openings; avoid hydrodissection along tissue planes
 - debridement is important in crush injuries to reduce infection and optimize cosmetic and functional repair
 - culture wound if signs of infection (erythema, necrosis or pus); obtain anaerobic cultures if wound foul smelling, necrotizing, or abscess; notify lab that sample is from bite wound
- **prophylactic antibiotics**
 - types of infections resulting from bites: cellulitis, lymphangitis, abscesses, tenosynovitis, osteomyelitis, septic arthritis, sepsis, endocarditis, meningitis
 - a 3-5 day course of antibiotics is recommended for all bite wounds to the hand and should be considered in other bites if any high-risk factors present (efficacy not proven)
 - dog and cat bites (pathogens: *Pasteurella multocida*, *S. aureus*, *S. viridans*)
 - ♦ 80% of cat bites, 5% of dog bites become infected
 - ♦ 1st line: amoxicillin + clavulanic acid
 - human bites (pathogens: *Eikenella corrodens*, *S. aureus*, *S. viridans*, oral anaerobes)
 - ♦ 1st line: amoxicillin + clavulanic acid
 - rabies (see [Infectious Diseases](#), ID8)
 - ♦ reservoirs: warm-blooded animals except rodents, lagomorphs (e.g. rabbits)
 - ♦ post-exposure vaccine is effective; treatment depends on local prevalence
 - suturing
 - ♦ vascular structures (i.e. face and scalp) are less likely to become infected, therefore consider suturing
 - ♦ allow avascular structures (i.e. pretibial regions, hands and feet) to heal by secondary intention
 - tetanus immunization if >10 yrs or incomplete primary series

High Risk Criteria for Infection

Wound Factors

- Puncture wounds
- Crush injuries
- Wounds >12 hrs old
- Hand or foot wounds
- Wounds near joints

Patient Factors

- Immunocompromised
- Age >50 years
- Prosthetic joints or valves

Consider Admission if:

- Moderate to severe infections
- Infections in immunocompromised patients
- Not responding to oral Rx
- Penetrating injuries to tendons, joints, CNS
- Open fractures

Snake Bites

- history, physical exam, investigations and initial management similar to mammalian bites
- additional management issues
 - snake bites are rarely fatal but proper precautions must be taken
 - supportive management, observe for compartment syndrome, analgesia, tetanus prophylaxis
 - contact regional Poison Control Centre for consultation
 - constriction band should be placed proximal to bite
 - observe for signs and symptoms of envenomation 15min-2hrs after bite (pain, sweating, edema, chills, weakness, numbness, tingling, HR changes, faintness, ecchymosis, N/V); if no envenomation then remove band and monitor closely for 24 hrs
 - if envenomation present, administer antivenom

Insect Bites

- **Bee Stings**
 - 5 types of reactions to stings (local, large local, systemic, toxic, unusual)
 - history and physical exam key to diagnosis; no lab test will confirm
 - investigations: CBC, electrolytes, BUN, creatinine, glucose, ABGs, ECG
 - ABC management, epinephrine 0.1 mg IV over 5 minutes if shock, antihistamines, cimetidine 300mg IV/IM/PO, steroids, β-agonists for SOB/wheezing 3 mg in 5 mL NS via nebulizer, local site management
- **West Nile Virus** (see [Infectious Diseases](#), ID28)
 - severity: asymptomatic 80%, flu-like symptoms 20%, encephalitis <1%
 - clues: aseptic meningitis/encephalitis in late summer in prevalent area
 - incubation 3-14 days, symptoms last 3-6 days
 - general symptoms: fever, malaise, anorexia, headache, altered mental status, motor weakness, ataxia, extrapyramidal signs, GI signs, myalgias, lymphadenopathy, rash, myocarditis, optic neuritis
 - investigations: CBC, electrolytes, CSF, CT/MRI
 - diagnosis: CSF and serum for serology
 - management: ABCs, IV fluids for dehydration, antibiotics if meningitis (based on CSF analysis), analgesia, antipyretics, interferon-α 2b, ribavirin

Near Drowning

- most common in children <4 yrs and teenagers
- causes lung damage, hypoxemia and may lead to hypoxic encephalopathy
- must also assess for shock, C-spine injuries, hypothermia, scuba-related injuries (barotrauma, air emboli, lung re-expansion injury)
- complications: volume shifts, electrolyte abnormalities, hemolysis, rhabdomyolysis, ATN, DIC

Physical Examination

- ABCs, vitals: watch closely for hypotension
- lungs: rales (ARDS, pulmonary edema), decreased breath sounds (pneumothorax)
- CVS: murmurs, arrhythmias, JVP (CHF, pneumothorax)
- H&N: assess for C-spine injuries
- neuro: GCS or AVPU, pupils, focal deficits

Investigations

- labs: CBC, electrolytes, ABGs, Cr, BUN, urinalysis
- imaging: CXR (pulmonary edema, pneumothorax)
- ECG

Management

- ABCs, treat for trauma, shock, hypothermia
- cardiac and O₂ sat monitors, IV access
- intensive respiratory care
 - ventilator assistance if decreased respirations, pCO₂ >50 mmHg, or pO₂ <60 mmHg on max O₂
 - may require intubation for airway protection, ventilation, pulmonary toilet
 - high flow O₂/CPAP/BiPAP may be adequate but some may need mechanical ventilation with PEEP
- arrhythmias: usually respond to corrections of hypoxemia, hypothermia, acidosis
- vomiting: very common, NG suction to avoid aspiration
- convulsions: usually respond to O₂; if not, diazepam 5-10 mg IV slowly
- bronchospasm: bronchodilators
- bacterial pneumonia: not necessary to prophylax with antibiotics unless contaminated water or hot-tub (*Pseudomonas*)
- must observe for at least 24 hours as non-cardiogenic pulmonary edema may develop late

Disposition

- non-significant submersion – discharge after short observation
- significant submersion (even if asymptomatic) – long period of observation (24 hrs) as pulmonary edema may appear late
- CNS symptoms or hypoxemia – admit
- severe hypoxemia, decreased LOC – ICU

Toxicology

Alcohol Related Emergencies

- see Psychiatry, PS20

Acute Intoxication

- slurred speech, CNS depression, disinhibition, lack of coordination
- nystagmus, diplopia, dysarthria, ataxia → may progress to coma
- frank hypotension (peripheral vasodilation)
- if obtunded rule out
 - head trauma/intracranial hemorrhage
 - associated depressant/street drugs, toxic alcohols
 - ♦ may also contribute to respiratory/cardiac depression
 - hypoglycemia (screen with bedside glucometer)
 - hepatic encephalopathy: confusion, altered LOC, coma
 - ♦ precipitating factors: GI bleed, infection, sedation, electrolyte abnormalities, protein meal
 - Wernicke's encephalopathy (ataxia, ophthalmoplegia, delirium)
 - post-ictal state, basilar stroke

Alcohol levels correlate poorly with intoxication.

Alcohol intoxication may invalidate informed consent.

Withdrawal

- beware withdrawal signs (see Table 22)
- treatment
 - diazepam 10-20 mg IV or PO OR lorazepam 2-4 mg IV or PO q1hr until calm
 - may use CIWA protocol and give benzodiazepines as above until CIWA <10
 - thiamine 100 mg IM then 50-100 mg/day
 - magnesium sulfate 4 g IV over 1-2 h (if hypomagnesemic)
 - admit patients with delirium tremens (DT), arrhythmias, or multiple seizures

Table 22. Alcohol Withdrawal Signs

Time Since Last Drink	Syndrome	Description
6-8 hr	Mild withdrawal	Generalized tremor, anxiety, agitation, but no delirium Autonomic hyperactivity (sinus tachycardia), insomnia, nausea, vomiting
1-2 days	Alcoholic hallucinations	Visual (most common), auditory and tactile hallucinations Vitals often normal
8 hr-2 days	Withdrawal seizures	Typically brief generalized tonic-clonic seizures May have several within a few hours
3-5 days	Delirium tremens (DT)	5% of untreated withdrawal patients Severely confused state, fluctuating levels of consciousness Agitation, insomnia, hallucinations/delusions, tremor Tachycardia, hyperpyrexia, diaphoresis High mortality rate

**CIWA Withdrawal Symptoms**

Nausea and vomiting
Tremor
Paroxysmal sweats
Anxiety
Agitation
Visual disturbances
Tactile disturbances
Auditory disturbances
Headache
Disorientation

10 symptoms each scored out of 7
except orientation is out of 4.

Seizures

- associated with ingestion and withdrawal
- withdrawal seizures
 - occur 8-48 hrs after last drink (typically brief generalized tonic-clonic seizures)
 - if >48 hrs, think of DT (see Table 22)
- prophylaxis: diazepam 20 mg PO q1h x 3 minimum, regardless of CIWA score
- CT head if focal seizures have occurred

Cardiovascular Complications

- HTN
- cardiomyopathy: SOB, edema
- arrhythmias ("holiday heart")
 - atrial fibrillation (most common), atrial flutter, SVT, VT (especially Torsades if hypomagnesemic/hypokalemic)

Metabolic Abnormalities

- alcoholic ketoacidosis
 - history of chronic alcohol intake with abrupt decrease/cessation
 - malnourished, abdominal pain with nausea and vomiting
 - anion gap (AG) metabolic acidosis, urine ketones, low glucose and normal osmolality
 - treatment: dextrose, thiamine (50-100 mg prior to dextrose), volume repletion (with NS)
 - generally resolves in 12-24 hr
- other alcohols
 - ethylene glycol → CNS, CVS, renal findings
 - methanol
 - ◆ early: lethargy, confusion
 - ◆ late: headache, visual changes, N/V, abdominal pain, tachypnea
 - both produce severe metabolic acidosis with AG and osmolar gap
 - EtOH co-ingestion is protective
 - treatment
 - ◆ fomepizole 15 mg/kg IV bolus OR EtOH 10% IV bolus and drip to achieve blood level of 20 mmol/L
 - EtOH loading may be done PO
 - ◆ consider folic acid for methanol and pyridoxime for ethylene glycol – both help reduce conversion to active metabolites
 - ◆ urgent hemodialysis required
- other abnormalities associated with alcohol: hypomagnesemia, hypophosphatemia, hypocalcemia, hypoglycemia, hypokalemia

**Common Deficiencies**

- Thiamine
- Niacin
- Folate
- Glycogen
- Magnesium
- Potassium

Gastrointestinal Abnormalities

- gastritis
 - common cause of abdominal pain and GI bleed in chronic alcohol users
- pancreatitis
 - serum amylase very unreliable in patients with chronic pancreatitis, may need serum lipase
 - hemorrhagic form (15%) associated with increased mortality
 - fluid resuscitation very important
- hepatitis
 - AST/ALT ratio >2 suggests alcohol as the cause as well as elevated GGT with acute ingestion

- peritonitis/spontaneous bacterial peritonitis
 - occasionally accompanies cirrhosis
 - leukocytosis, fever, generalized abdominal pain/tenderness
 - paracentesis for diagnosis (common pathogens: *E. coli*, *Klebsiella*, *Strep*)
- GI bleeds
 - most commonly gastritis or ulcers, even if patient known to have varices
 - consider Mallory-Weiss tear secondary to retching
 - often complicated by underlying coagulopathies
 - minor – treat with antacids
 - severe or recurrent – endoscopy

Miscellaneous Problems

- rhabdomyolysis
 - presents as acute weakness associated with muscle tenderness
 - usually occurs after prolonged immobilization
 - increased creatinine kinase (CK), hyperkalemia
 - myoglobinuria – may lead to acute renal failure
 - treatment: IV fluids, forced diuresis (mannitol 20% 15 mg/kg IV over 30 min)
- increased infections – due to impaired host defenses, immunocompromise, poor living conditions

Disposition

- before patient leaves ED ensure
 - stable vital signs
 - can walk unassisted
 - fully oriented
- offer social services to find shelter or detox program
- ensure patient can obtain any medications prescribed and can complete any necessary follow-up

Approach to the Overdose Patient

History

- who? age, weight, underlying medical problems, medications
- what? substance and how much
- when? time since exposure determines prognosis and need for decontamination, symptoms since
- how? route
- why? intention, suicidality

Physical Examination

- focus on: ABCs, LOC/GCS, vitals, pupils

Principles of Toxicology

- 4 principles to consider with all ingestions
 - I. resuscitation (ABCs)
 - II. screening (toxidrome? clinical clues?)
 - III. decrease absorption of drug
 - IV. increase elimination of drug

ABCs of Toxicology

- basic axiom of care is symptomatic and supportive treatment
- address underlying problem only once patient is stable
 - A Airway (consider stabilizing the C-spine)
 - B Breathing
 - C Circulation
 - D1 Drugs
 - ACLS as necessary to resuscitate the patient
 - universal antidotes
 - D2 Draw bloods
 - D3 Decontamination (decrease absorption)
 - E Expose (look for specific toxidromes)/Examine the Patient
 - F Full vitals, ECG monitor, Foley, x-rays, etc.
 - G Give specific antidotes, treatments
- Go back and reassess
- Call poison information centre
- Obtain corroborative history from family, bystanders

Suspect Overdose when:

- Altered level of consciousness/coma
- Young patient with life-threatening arrhythmia
- Trauma patient
- Bizarre or puzzling clinical presentation

D1 – Universal Antidotes

- treatments that will not harm patients and may be essential

Oxygen

- do not deprive a hypoxic patient of oxygen no matter what the antecedent medical history (i.e. even COPD with CO₂ retention)
- if depression of hypoxic drive, intubate and ventilate
- exception: paraquat or diquat (herbicides) inhalation or ingestion (oxygen radicals increase morbidity)

Glucose

- give to any patient presenting with altered LOC
- measure blood glucose prior to glucose administration if possible
- adults: 0.5-1.0 g/kg (1-2 mL/kg) IV of D50W
- children: 0.25 g/kg (2-4 mL/kg) IV of D25W

Thiamine (Vitamin B1)

- 100 mg IV/IM to all patients with IV/PO glucose
- a necessary cofactor for glucose metabolism, but do not delay glucose if thiamine unavailable
- to prevent Wernicke-Korsakoff syndrome
- must assume all undifferentiated comatose patients are at risk

Naloxone (central μ -receptor competitive antagonist, shorter $t_{1/2}$ than naltrexone)

- antidote for opioids: administration is both diagnostic and therapeutic (1 min onset of action)
- used for the undifferentiated comatose patient
- loading dose
 - adults
 - ♦ 2 mg initial bolus IV/IM/SL/SC or via ETT (ETT dose = 2-2.5x IV dose)
 - ♦ if no response after 2-3 minutes, increase dose by 2 mg increments until a response or to max 10 mg
 - ♦ known chronic user, suspicious history, or evidence of track marks, give 0.01 mg/kg
 - child
 - ♦ 0.01 mg/kg initial bolus IV/IO/ETT
 - ♦ 0.1 mg/kg if no response and narcotic still suspected to max of 10 mg
- maintenance dose
 - may be required because half-life of naloxone (30-80 mins) is much shorter than many narcotics
 - ♦ hourly infusion rate at 2/3 of initial dose that produced patient arousal

Populations at Risk for Thiamine Deficiency

- Alcoholics
- Anorexics
- Hyperemesis of pregnancy
- Malnutrition states

Administration of naloxone can cause opiate withdrawal in chronic users. Minor withdrawal may present as lacrimation, rhinorrhea, diaphoresis, yawning, piloerection, HTN, and tachycardia. Severe withdrawal may present as hot and cold flashes, arthralgias, myalgias, N/V, and abdominal cramps.

D2 – Draw Bloods

- essential tests (see Table 24)
 - CBC, electrolytes, BUN/creatinine, glucose, INR/PTT, osmolality
 - ABGs, measure O₂ sat
 - acetylsalicylic acid (ASA), acetaminophen, EtOH levels
- potentially useful tests
 - drug levels – this is NOT a serum drug screen
 - Ca, Mg, PO₄
 - protein, albumin, lactate, ketones, liver enzymes, CK – depending on drug and clinical presentation

Serum Drug Levels

- treat the patient, not the drug level
- negative tox screen does not rule out a toxic ingestion – signifies only that the specific drugs tested were not detectable in the specimen
- specific drugs available on general screen vary by institution; check before ordering
- urine screens also available (qualitative only)

Plasma Osmolar Gap (POG)
 $= (2 \text{ Na} + \text{glucose} + \text{urea}) - \text{plasma osmolarity}$
 Normal POG < 10 mOsm/kg

Anion Gap (AG)
 $= \text{Na} - \text{Cl} - \text{bicarb}$
 Normal AG ≤ 12 mEq/L

Table 23. Toxic Gaps (see also [Nephrology](#))

METABOLIC ACIDOSIS

Increased AG: "MUDPILES CAT" (* = toxic)

Methanol*
Uremia
Diabetic ketoacidosis/Starvation ketoacidosis
Phenformin*/Paraldehyde*
Isoniazid, Iron, Ibuprofen
Lactate (anything that causes seizures or shock)
Ethylene glycol*
Salicylates*
Cyanide, carbon monoxide*
Alcoholic Ketoacidosis
Toluene, theophylline*

Decreased AG

Electrolyte imbalance (increased Na/K/Mg)
 Hypoalbuminemia (50% fall in albumin ~ 5.5 mmol/L decrease in the AG)
 Li, Br elevation
 Paraproteins (multiple myeloma)

Normal AG

High K: pyelonephritis, obstructive nephropathy, renal tubular acidosis (RTA), IV, TPN
 Low K: small bowel losses, acetazolamide, RTA I, II

Increased POG: "MAE DIE" (if it ends in "-ol", it will likely \uparrow the POG)

Methanol
Acetone
Ethanol
Diuretics (glycerol, mannitol, sorbitol)
Isopropanol
Ethylene glycol

Note: normal osmolar gap does not rule out toxic alcohol; only an elevated gap is helpful

Increased O₂ saturation gap

Carboxyhemoglobin
 Methemoglobin
 Sulfmethemoglobin

Table 24. Use of the Clinical Laboratory in the Initial Diagnosis of Poisoning

Test	Finding	Selected Causes
ABG	Hypoventilation (\uparrow pCO ₂) Hyperventilation (\downarrow pCO ₂)	CNS depressants (opioids, sedative-hypnotic agents, phenothiazines, EtOH) Salicylates, CO, other asphyxiants
Electrolytes	\uparrow anion-gap metabolic acidosis Hyperkalemia Hypokalemia	"MUDPILES CAT" : see "Metabolic Acidosis" above Digitalis glycosides, fluoride, potassium Theophylline, caffeine, beta-adrenergic agents, soluble barium salts, diuretics, insulin
Glucose	Hypoglycemia	Oral hypoglycemia agents, insulin, EtOH, ASA
Osmolality and Osmolar Gap	Elevated osmolar gap	"MAE DIE" : see "Toxic Gaps" above
ECG	Wide QRS complex Prolonged QT interval Atrioventricular block	TCAs, quinidine, other class Ia and Ic antiarrhythmic agents Quinidine and related antiarrhythmics, terfenadine, astemizole, antipsychotics Ca antagonists, digitalis glycosides, phenylpropanolamine
Abdominal X-Ray	Radiopaque pills or objects	"CHIPES" : Calcium, Chloral hydrate, CCl ₄ , Heavy metals, Iron, Potassium, Enteric coated Salicylates, and some foreign bodies
Serum Acetaminophen	Elevated level (> 140 mg/L or 1000 μ mol/L 4 hours after ingestion)	May be only sign of acetaminophen poisoning

D3 – Decontamination and Enhanced Elimination

Ocular Decontamination

- saline irrigation to neutralize pH; alkali exposure requires ophthalmology consult

Dermal Decontamination (wear protective gear)

- remove clothing, brush off toxic agents, irrigate all external surfaces

Gastrointestinal Decontamination

- single dose activated charcoal (SDAC) (see Table 27 for drug toxidromes that are treated with charcoal)
 - adsorption of drug/toxin to AC prevents availability
 - contraindications: caustics, SBO, perforation
 - dose: 10g/g drug ingested or 1g/kg body weight
 - odourless, tasteless, prepared as slurry with H₂O
- whole bowel irrigation
 - 500 mL (child) to 2000 mL (adult) of polyethylene glycol solution/hour by mouth until clear effluent per rectum
 - start slow (500 mL in an adult) and aim to increase rate hourly as tolerated
 - indications
 - ♦ awake, alert, can be nursed upright
 - ♦ delayed release product
 - ♦ drug/toxin not bound to charcoal
 - ♦ drug packages (if any evidence of breakage \rightarrow emergency surgery)
 - ♦ recent toxin ingestion

Substances NOT Adsorbed by Activated Charcoal

- Lithium
- Iron
- Alcohols
- Lead
- Caustics

- contraindications
 - evidence of ileus, perforation, or obstruction
- surgical removal in extreme cases
 - indicated for drugs that are toxic, form concretions, or cannot be removed by conventional means
- no evidence for the use of cathartics (or ipecac)

EXTRA-CORPOREAL DRUG REMOVAL (ECDR)

Urine Alkalinization

- may be used for: ASA, methotrexate, phenobarbital, chlorpropamide
- weakly acidic substances can be trapped in alkali urine (pH >7.5) to increase elimination

Multidose Activated Charcoal (MDAC)

- may be used for: carbamazepine, phenobarbital, quinine, theophylline
- for toxins which undergo enterohepatic recirculation
- removes drug that has already been absorbed by drawing it back into GI tract
- various regimens: 12.5 g (1/4 bottle) PO q1h or 25 g (1/2 bottle) PO q2h until non-toxic

Hemodialysis

- indications/criteria for hemodialysis
 - toxins that have high water solubility, low protein binding, low molecular weight, adequate concentration gradient, small volume of distribution (Vd) or rapid plasma equilibration
 - removal of toxin will cause clinical improvement
 - advantage is shown over other modes of therapy
 - predicted that drug or metabolite will have toxic effects
 - impairment of normal routes of elimination (cardiac, renal, or hepatic)
 - clinical deterioration despite maximal medical support
- useful for the following blood toxins:
 - methanol
 - ethylene glycol
 - salicylates
 - lithium
 - phenobarbital: 430-650 mmol/L
 - chloral hydrate (→ trichloroethanol): >200 mg/kg
- others include theophylline, carbamazepine, valproate, methotrexate

E – Examine the Patient

- vital signs (including temperature), skin (needle tracks, colour), mucous membranes, pupils, odours and CNS
- head-to-toe survey including
 - C-spine
 - signs of trauma, seizures (incontinence, “tongue biting”, etc.), infection (meningismus), chronic alcohol/drug abuse (track marks, nasal septum erosion)
- mental status

Table 25. Specific Toxicodromes

Toxidrome	Overdose Signs and Symptoms	Examples of Drugs
Anticholinergics	Hyperthermia	Antidepressants (e.g. TCAs)
	Dilated pupils	Cyclobenzaprine (Flexeril®)
	Dry skin	Carbamazepine
	Vasodilation	Antihistamines (e.g. diphenhydramine)
	Agitation/hallucinations	Antiparkinsonians
	Ileus	Antipsychotics
	Urinary retention	Antispasmodics
	Tachycardia	Belladonna alkaloids (e.g. atropine)
Cholinergics	“DUMBELS”	Natural plants: mushrooms, trumpet flower
	Diaphoresis, D iarrrhea, D ecreased blood pressure	Anticholinesterases: physostigmine,
	Urination	Insecticides (organophosphates, carbamates)
	Miosis	Nerve gases
	Bronchospasm, B ronchorrhea, B radycardia	
	Emesis, Excitation of skeletal muscle	
	Lacrimation	
	Salivation, S eizures	
Extrapyramidal	Dysphonia, dysphagia	Major tranquilizers
	Rigidity and tremor	Antipsychotics
	Motor restlessness, crawling sensation (akathisia)	
	Constant movements (dyskinesia)	
	Dystonia (muscle spasms, laryngospasm, trismus, oculogyric crisis, torticollis)	

Table 25. Specific Toxidromes (continued)

Toxidrome	Overdose Signs and Symptoms	Examples of Drugs
Hemoglobin Derangements	Increased respiratory rate Decreased level of consciousness Seizures Cyanosis unresponsive to O ₂ Lactic acidosis	Carbon monoxide poisoning (carboxyhemoglobin) Drug ingestion (methemoglobin, sulfmethemoglobin)
Narcotics, Sedatives/Hypnotics, EtOH	Hypothermia Hypotension Respiratory depression Dilated or constricted pupils (pinpoint in opiate OD) CNS depression	EtOH Benzodiazepines Opiates (morphine, heroin, etc.) Barbiturates GHB
Sympathomimetics	Increased temperature CNS excitation (including seizures) Tachycardia, hypertension Nausea and vomiting Diaphoresis Dilated pupils	Amphetamines, caffeine, cocaine, LSD, PCP Ephedrine and other decongestants Thyroid hormone Sedatives, EtOH withdrawal
Serotonin Syndrome	Mental status changes, autonomic hyperactivity, neuromuscular abnormalities, hyperthermia, diarrhea, HTN	MAOI, TCA, SSRI, opiate analgesics Cough medicine, weight reduction medications

Note: ASA poisoning and hypoglycemia mimic sympathomimetic toxidrome

G – Give Specific Antidotes and Treatments

Urine Alkalinization Treatment for ASA Overdose

- urine pH >7.5
- fluid resuscitate first, then 3 amps NaHCO₃/litre of D5W @ 1.5 x maintenance
- add 20-40 mEq KCl/litre if patient is able to urinate

Table 26. Protocol for Warfarin Overdose

INR	Management
<5.0	Cessation of warfarin administration, observation, serial INR/PT
5.1–9.0	If no risk factors for bleeding, hold warfarin x 1-2 days and reduce maintenance dose OR Vitamin K 1-2 mg PO if patient at increased risk of bleeding or fresh frozen plasma (FFP) if active bleed
9.1–20.0	Hold warfarin, Vitamin K 2-4 mg PO, serial INR/PT, additional Vitamin K if necessary or FFP if active bleed
>20.0	FFP 10-15 mL/kg, Vitamin K 10 mg IV over 10 min, increase Vitamin K dosing (q4h) if needed

Table 27. Specific Antidotes and Treatments – call local poison information centre for specific doses and treatment recommendations

Toxin	Treatment	Considerations
Acetaminophen	Decontaminate (activated charcoal) N-acetylcysteine	Often clinically silent; evidence of liver/renal damage delayed >24 hrs Toxic dose >200 mg/kg (>7.5 g adult) Monitor drug level immediately and 4 hrs post-ingestion; also liver enzymes, INR, PTT, BUN, Cr Hypoglycemia, metabolic acidosis, encephalopathy → poor prognosis
ASA	Decontaminate (activated charcoal) Alkalinize urine; want urine pH >7.5	Monitor serum pH and drug levels closely Monitor K level; may require supplement for urine alkalinization Hemodialysis may be needed if intractable metabolic acidosis, very high levels, or end-organ damage (i.e. unable to diurese)
Anticholinergics	Decontaminate (activated charcoal) Supportive care	Special antidotes available. Consult Poison Information Centre (PIC)
Benzodiazepines	Decontaminate (activated charcoal) Supportive care	
β-blockers	Decontaminate (activated charcoal) Consider glucagon or high dose insulin euglycemia therapy (HDIE)	Consult PIC
Calcium Channel Blockers	CaCl ₂ 1-4 g of 10% sol'n IV if hypotensive Atropine or isoproterenol if severe Other: HDIE inotropes or aggressive supportive therapy	Order ECG, electrolytes (especially Ca, Mg, Na, K), glucagon may help (2-5 mg)
Cyanide	Cyanide antidote kit or hydroxycobalamin	

Table 27. Specific Antidotes and Treatments – call local poison information centre for specific doses and treatment recommendations (continued)

Toxin	Treatment	Considerations
Digoxin	Decontaminate (activated charcoal) Digoxin-specific Ab fragments 10-20 vials IV if acute; 3-6 if chronic 1 vial (40 mg) neutralizes 0.5 mg of toxin	Use for life-threatening arrhythmias unresponsive to conventional therapy, 6 hr serum digoxin >19 nmol/L, initial K >5 mM, ingestion >10 mg (adult) / >4 mg (child) Common arrhythmias include VFib, VTach, and conduction blocks
Acute Dystonic Rxn	Benztropine: 1-2 mg IM/IV then 2 mg PO x 3 days OR Diphenhydramine 1-2 mg/kg IV, then 25 mg PO qid x 3 days	Benzotropine (Cogentin®) has euphoric effect and potential for abuse
Heparin	Protamine sulfate 25-50 mg IV	For unfractionated heparin overdose only
Insulin/ Oral Hypoglycemic	Glucose IV/PO/NG tube Glucagon: 1-2 mg IM (if no access to glucose)	Glyburide carries highest risk of hypoglycemia among oral agents Consider octreotide for oral hypoglycemics (50-100 µg SC q6h) in these cases; consult local PIC
Ethanol	Thiamine 100 mg IM/IV Manage airway and circulatory support	Hypoglycemia very common in children Mouthwash = 70% EtOH; perfumes and colognes = 40-60% EtOH Order serum EtOH level and glucose level; treat glucose level appropriately
Ethylene Glycol/ Methanol	Ethanol (10%) 10 ml/kg over 30 min, then 1.5 ml/h or fomepizole (4-methylpyrazole) 15 mg/kg IV load over 30 min, then 10 mg/kg q12h	CBC, electrolytes, glucose, ethanol level Consider hemodialysis
CO Poisoning	See ER46	
Opioids	See ER51	
TCAs	Aggressive supportive care NaHCO ₃ bolus for wide QRS/seizures	Flumazenil antidote contraindicated in combined TCA and benzodiazepine overdose Also consider cardiac and hypotension support, gastric decontamination, seizure control Intralipid therapy (consult local PIC)
MDMA	Decontaminate (activated charcoal), supportive care	Monitor CK; treat rhabdomyolysis with high flow fluids
Cocaine	Decontaminate (activated charcoal) if oral Aggressive supportive care	β-blockers are contraindicated in acute cocaine toxicity

Disposition from the Emergency Department

- methanol, ethylene glycol
 - delayed onset, admit and watch clinical and biochemical markers
- TCAs
 - prolonged/delayed cardiotoxicity warrants admission to monitored (ICU) bed
 - if asymptomatic and no clinical signs of intoxication: 6 hour ED observation adequate with proper decontamination and no ECG abnormalities
 - sinus tachycardia alone (most common finding) with history of OD warrants observation in ED
- hydrocarbons/smoke inhalation
 - pneumonitis may lag 6-8 hours
 - consider observation for repeated clinical and radiographic examination
- ASA, acetaminophen
 - if borderline level, get second level 2-4 hours after first
 - for ASA must have at least 2 levels going down before discharge (3 levels minimum)
- oral hypoglycemics
 - admit all patients for minimum 24 hours if hypoglycemic
 - observe asymptomatic patient for at least 8 hours

Psychiatric Consultation

- once patient medically cleared, arrange psychiatric intervention if required
- beware – suicidal ideation may not be expressed

Psychiatric Emergencies

Approach to Common Psychiatric Presentations

- see [Psychiatry](#)
- before seeing patient, ensure your own safety; have security/police available if necessary

History

- safety
 - assess suicidality: suicidal ideation, intent, plan, lethal means, past attempts
 - assess homicidality: access to weapons, intended victim, history of violence
 - command hallucinations
- identify current stressors and coping strategies
- mood symptoms: manic, depressive
- anxiety: panic attacks, generalized anxiety, phobias, OCD, PTSD
- psychotic symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behaviour, negative symptoms (affective flattening, alogia, avolition)
- substance use history: most recent use, amount, previous withdrawal reactions
- past psychiatric history, medications, adherence with medications
- medical history: obtain collateral if available

Physical

- complete physical exam focusing on: vitals, neurological exam, signs of head trauma, signs of drug toxicity, signs of metabolic disorder
- mental status exam: general appearance, behavior, cooperation, speech, mood and affect, thought content and form, perceptual disturbances, cognition (including MMSE if indicated), judgment, insight, reliability

Investigations

- investigations vary with: age, established psychiatric diagnosis vs. first presentation, history and physical suggestive of organic cause
- as indicated: blood glucose, urine and serum toxicology screen, pregnancy test, electrolytes, TSH, AST/ALT, bilirubin, serum creatinine, BUN, osmolality
- blood levels of psychiatric medications
- CT head if suspect neurological etiology
- LP if indicated

Acute Psychosis

Differential Diagnosis

- primary psychotic disorder (e.g. schizophrenia)
- secondary to medical condition (e.g. delirium)
- drugs: substance intoxication or withdrawal, medications (e.g. steroids, anticholinergics)
- infectious (CNS)
- metabolic (hypoglycemic, hepatic, renal, thyroid)
- structural (hemorrhage, neoplasm)

Management

- violence prevention
 - remain calm, empathic and reassuring
 - ensure safety of staff and patients, have extra staff and/or security on hand
 - patients demonstrating escalating agitation or overt violent behavior may require physical restraint and/or chemical tranquilization (see *Violent Patient*, ER57)
- treat agitation: whenever possible, offer medication to patients as opposed to administering with force (helps calm and engage patient)
 - benzodiazepines – lorazepam 2 mg PO, IM or SL
 - antipsychotics – olanzapine 5 mg PO, haloperidol 5 mg PO/IM
- treat underlying medical condition
- psychiatry or Crisis Intervention Team consult

Key Functions of Emergency Psychiatric Assessment

1. Is the patient medically stable?
2. Rule out medical cause
3. Is psychiatric consult needed?
4. Are there safety issues (SI, HI)?
5. Is patient certifiable? (must demonstrate risk [present/past test] and apparent mental illness [future test])

Features that suggest Organic Etiology

Age > 40 years old
 Babbling (incoherent speech or speech difficulties)
 Concerning vital signs
 Disorientation
 Emotional lability
 Fluctuating course
 Global impairment of cognitive function
 Headaches
 Immodesty
 Just started (sudden onset)
 K
 Loss of consciousness
 Movement abnormalities (tremor, ataxia, psychomotor retardation)
 Neurological findings (focal)
 Other abnormalities on physical exam
 Perceptions (visual hallucinations)

Suicidal Patient

Epidemiology

- attempted suicide F>M, completed suicide M>F
- second leading cause of death in people <24 years

Management

- ensure patient safety: close observation, remove potentially dangerous objects from person and room
- assess thoughts (ideation), means, action (preparatory, practice attempts), previous attempts
- admit if there is evidence of intent and organized plan, access to lethal means, psychiatric disorder, intoxication (suicidal ideation may resolve with few days of abstinence)
- patient may require certification if unwilling to stay voluntarily
- do not start long-term medications in the emergency department
- psychiatry or crisis team consult

Violent Patient

Differential Diagnosis

- rule out lethal organic cause (e.g. EtOH, drugs, and head injuries)

Prevention

- be aware and look for prodromal signs of violence: anxiety, restlessness, defensiveness, verbal attacks
- try to de-escalate the situation: address the patient's anger, empathize

Restraints

- pharmacological
 - often necessary – may mask clinical findings and impair exam
 - haloperidol 5-10 mg IM (be prepared for dystonic reactions, especially with multiple doses of neuroleptics over a short period) + lorazepam 2 mg IM/IV
 - look for signs of anticholinergic overdose first (see Table 25)
 - benzodiazepines best option if suspected substance-induced violence
- physical
 - present option to patient in firm but non-hostile manner
 - sufficient people to carry it out safely
 - restrain supine or on side; preferably 4-point restraints, never less than 2-points (opposite arm and leg)
 - suction and airway support available in case of vomiting
- once restrained, search person/clothing for drugs and weapons

See **Psychiatry**, PS24 for certification considerations

High Risk Patients

SAD PERSONS

Sex = male
Age >45 years old
Depression
Previous attempts
Ethanol use
Rational thinking loss
Suicide in family
Organized plan
No spouse, no support system
Serious illness

Common Pediatric ER Presentations

Modified Coma Score

Table 28. Modified GCS

Modified GCS for Infants

Eye Opening	Verbal Response	Motor Response
4 – spontaneously	5 – coos, babbles	6 – normal, spontaneous movement
3 – to speech	4 – irritable cry	5 – withdraws to touch
2 – to pain	3 – cries to pain	4 – withdraws to pain
1 – no response	2 – moans to pain	3 – decorticate flexion
	1 – no response	2 – decerebrate extension
		1 – no response

Modified GCS for Children <4 years

Eye Opening	Verbal Response	Motor Response
4 – spontaneously	5 – oriented, social, speaks, interacts	6 – normal, spontaneous movement
3 – to speech	4 – confused speech, disoriented, consolable	5 – localizes pain
2 – to pain	3 – inappropriate words, not consolable/aware	4 – withdraws to pain
1 – no response	2 – incomprehensible, agitated, restless, not aware	3 – decorticate flexion
	1 – no response	2 – decerebrate extension
		1 – no response

Any infant <1 year of age with a large, boggy scalp hematoma requires CT.

Respiratory Distress

In pediatric respiratory distress, must also rule out:

- Anaphylaxis
- Foreign body
- Pneumonia
- Bronchiolitis

- see also [Pediatrics](#)

History and Physical Examination

- infants not able to feed, older children not able to speak in full sentences
- anxious, irritable, lethargic – may indicate hypoxia
- tachypnea >60 (>40 if preschool age, >30 if school age), retractions, tracheal tug
 - see [Pediatrics](#) Table 1 for age specific vital signs
- pulsus paradoxus
- wheezing, grunting, vomiting

Table 29. Stridorous Upper Airway Diseases: Diagnosis

Feature	Croup	Bacterial Tracheitis	Epiglottitis ¹
Age Range (yrs)	0.5-4	5-10	2-8
Prodrome	Days	Hrs to days	Minutes to hrs
Temperature	Low grade	High	High
Radiography	Steeple sign	Exudates in trachea	Thumb sign
Etiology	Parainfluenza	<i>S. aureus</i> /GAS	<i>H. flu</i> type b
Barky Cough	Yes	Yes	No
Drooling	Yes	No	Yes
Appear Toxic	No	Yes	Yes
Intubation? ICU?	No	Yes	Yes
Antibiotics	No	Yes	Yes
NOTE:			No oral exam

¹Now rare with Hib vaccine in common use

Admission Criteria for Croup

- Stridor at rest or significant respiratory distress
- Relapse after 2 doses of epinephrine or incomplete response
- Co-morbid respiratory or underlying condition

- **management of croup (laryngotracheitis caused by parainfluenza viruses)**
 - humidified O₂ should not be given (no evidence for efficacy)
 - racemic epinephrine q1h x 3 doses, observe for 'rebound effects'
 - dexamethasone x 1 dose
 - consider bacterial tracheitis/epiglottitis if unresponsive to croup therapy
- **management of bacterial tracheitis**
 - start croup therapy, but may have poor response
 - usually require intubation, ENT consult, ICU
 - start antibiotics (e.g. cloxacillin), pending C&S
- **management of epiglottitis**
 - 4 D's: drooling, dyspnea, dysphagia, dysphonia + tripod sitting
 - do not examine oropharynx or agitate patient
 - immediate anaesthesia, ENT call – intubate
 - then IV fluids, Abx, blood cultures
- **management of asthma**
 - supplemental O₂ if sats <90% or PaO₂ <60%
 - bronchodilator therapy: salbutamol (Ventolin®) 0.15 mg/kg by masks q20 min x 3
 - add 250-500 µg ipratropium (Atrovent®) to first 3 doses salbutamol
 - give corticosteroid therapy as soon as possible after arrival (prednisolone 2 mg/kg, dexamethasone 0.3 mg/kg)
 - MgSO₄ if critically ill, not responding to inhaled bronchodilators, steroids; give IV bolus, then infusion
 - IV β₂-agonists if critically ill and not responding to above

Admission Criteria for Asthma

- Respiratory distress 6 hrs after steroids
- Ventolin required > q3h
- Need for supplemental oxygen
- Consider if previous ICU admission

Rochester Criteria for Febrile Infants Age 28-90 Days Old

- Non-toxic looking
- Previously well (>37 weeks GA, home with mother, no hyperbilirubinemia, no prior antibiotics or hospitalizations, no chronic/underlying illness)
- No skin, soft tissue, bone, joint, or ear infection on physical exam
- WBC 5000-15,000, bands <1500; urine <10 WBC/HPF, stool <5 WBC/HPF

Febrile Infant and Febrile Seizures

FEBRILE INFANT

- see also [Pediatrics](#)
- for fever >38°C without obvious focus
 - <28 days
 - ♦ admit
 - ♦ full septic work up (CBC & diff, blood C&S, urine C&S, CSF, CXR if indicated)
 - ♦ treat empirically with broad spectrum IV antibiotics
 - 28-90 days
 - ♦ as above unless infant meets Rochester criteria (see sidebar)
 - >90 days
 - ♦ toxic: admit, treat, full septic workup
 - ♦ non-toxic and no focus: investigate as indicated by history and physical

FEBRILE SEIZURES

- see [Pediatrics](#), P52

Etiology

- children aged 6 months to 5 years with fever or history of recent fever
- simple vs. complex febrile seizures
- normal neurological exam afterward
- no evidence of intracranial infection or history of previous non-febrile seizures
- often positive family history of febrile seizures
- relatively well looking after seizure

Investigations and Management

- if it is a febrile seizure: treat fever and look for source of fever
- if not a febrile seizure: treat seizure and look for source of seizure
 - note: may also have fever but may not meet criteria for febrile seizure

Table 30. Simple vs. Complex Febrile Seizures

Characteristic	Simple	Complex
Duration	< 15 min	> 15 min
Type of Seizure	Generalized	Focal features
Frequency	1 in 24 hours	> 1 in 24 hours

Abdominal Pain

- see also [Pediatrics](#), P41

History

- nature of pain, associated fever
- associated GI, GU symptoms
- anorexia, decreased fluid intake

Physical Examination

- HEENT, respiratory, abdominal exam including DRE, testicular/genital exam

Table 31. Differential Diagnosis of Abdominal Pain in Infants/Children/Adolescents

Medical	Surgical
Colic	Malrotation with volvulus
UTI	Hirschprung's
Constipation	Necrotizing enterocolitis
Gastroenteritis	Incarcerated hernia
Sepsis	Intussusception
HSP (Henoch Schonlein purpura)	Duodenal atresia
Inflammatory Bowel Disease	Appendicitis
HUS (Hemolytic Uremic Syndrome)	Cholecystitis
Pneumonia	Pancreatitis
Strep Throat	Testicular torsion
SCD crisis	Ectopic pregnancy
DKA	Trauma
Functional	Pyloric stenosis

*Remember to keep an index of suspicion for child abuse

Common Infections

- see also [Pediatrics](#)

Table 32. Antibiotic Treatment of Pediatric Bacterial Infections

Infection	Pathogens	Treatment
MENINGITIS		
SEPSIS		
Neonatal	GBS, <i>E. coli</i> , <i>Listeria</i> , <i>S. aureus</i> , Gram-negative bacilli	<ul style="list-style-type: none"> • ampicillin + aminoglycoside (gentamicin or • ampicillin + cefotaxime ± cloxacillin if risk of <i>S. aureus</i>
1-3 months	Same pathogens as above and below	• ampicillin + cefotaxime ± cloxacillin if risk of <i>S. aureus</i>
>3 months	<i>S. pneumococcus</i> , <i>H. influenzae</i> type b (>5 yrs), meningococcus	<ul style="list-style-type: none"> • cefuroxime • ceftriaxone or cefotaxime, if risk of meningitis • vancomycin, if penicillin/cephalosporin-resistant pneumococci
OTITIS MEDIA		
1st line	<i>S. pneumoniae</i> , <i>H. influenzae</i> type b, <i>M. Catarrhalis</i>	• amoxicillin 80-90 mg/kg per day
2nd line		• amoxicillin-clavulanate (Clavulin®)
Treatment failure		• high dose Clavulin® or cefuroxime or ceftriaxone
STREP PHARYNGITIS		
	Group A beta-hemolytic <i>Streptococcus</i>	• penicillin/amoxicillin or erythromycin (penicillin allergy)
UTI		
	<i>E. coli</i> , <i>Proteus</i> , <i>H. influenzae</i> , <i>Pseudomonas</i> , <i>S. saprophyticus</i> Enterococcus, GBS	<ul style="list-style-type: none"> • amoxicillin/ampicillin or • trimethoprim-sulfamethoxazole
PNEUMONIA		
1-3 months	Viral, <i>S. pneumoniae</i> , <i>C. trachomatis</i> , <i>B. pertussis</i> , <i>S. aureus</i> , <i>H. influenzae</i>	• cefuroxime ± macrolide (erythromycin) or ampicillin ± macrolide
3 months-5 years	Viral, <i>S. pneumoniae</i> , <i>S. aureus</i> , <i>H. influenzae</i> , <i>Mycoplasma pneumoniae</i>	• ampicillin/amoxicillin or cefuroxime
>5 years	As above	• ampicillin/amoxicillin + macrolide or cefuroxime + macrolide

Child Abuse and Neglect

- see also [Pediatrics](#)
- obligation to report **any** suspected/known case of child abuse or neglect to CAS yourself (do not delegate)
- document injuries
- consider skeletal survey x-rays, ophtho consult, CT head
- injury patterns associated with child abuse
 - head injuries: torn frenulum, dental injuries, bilateral black eyes, traumatic hair loss, diffuse severe CNS injury, retinal hemorrhage
 - Shaken Baby Syndrome: diffuse brain injury, subdural/subarachnoid hemorrhage, retinal hemorrhage, minimal/no evidence of external trauma, associated bony fractures
 - skin injuries: bites, bruises/burns in shape of an object, glove/stocking distribution of burns, bruises of various ages, bruises in protected areas
 - bone injuries: rib fractures without major trauma, femur fractures age <1 year of age, spiral fractures of long bones in non-ambulatory children, metaphyseal fractures in infants, multiple fractures of various ages, complex/multiple skull fractures
 - genitourinary/gastrointestinal injuries: chronic abdominal/perineal pain, injury to genitals/rectum, STI/pregnancy, recurrent vomiting or diarrhea

Presentation of Neglect

- Failure to thrive, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents, no stranger anxiety

Procedural Sedation

- procedural sedation: the technique of sedative or dissociative agent administration with or without analgesics to induce a state that allows a patient to tolerate an unpleasant or painful procedure while maintaining all protective cardiorespiratory functions (i.e. a depressed level of consciousness without loss of a patient's protective airway reflexes)
 - must weigh degree of pain and expected relief versus risk/complications of sedation and procedure
- examples of procedures that may require sedation in the emergency department:
 - setting fractures, reducing dislocations, draining abscesses, exploring wounds/ulcers/superficial infections, endoscopic examination
 - may also be required to reduce patient agitation if imaging is acutely required

Requirements for Safe Procedural Sedation in the Emergency Department

- airway suitable for safe intubation and ventilation
- appropriate equipment/personnel available
- intact and functioning cardiorespiratory and neurological system
- ideally, NPO for minimum 4-6 hours
- anesthetic history and drug allergies, including manifestations
- appropriate IV access, monitoring (oxygen saturation, BP, HR, etc.)
- informed consent obtained

Common Procedural Sedation Medications (titrate to effect)

- see *Common Medications*, below

Common Medications

Table 33. Commonly Used Medications

Drug	Dosing Schedule	Indications	Comments
fentanyl	0.5-1.0 µg/kg IV	Procedural sedation	Very short acting narcotic (complication=apnea)
midazolam	50 µg/kg IV	Procedural sedation	Short acting benzodiazepine (complication=apnea when used with narcotic) Fentanyl and midazolam often used together for procedural sedation
propofol	0.25-0.5 mg/kg IV	Procedural sedation	Short acting Anesthetic/sedative (complication=apnea, decreased BP)
flumazenil	0.3 mg IV bolus q5min x 3doses	Reversal of procedural sedation	Benzodiazepine antagonist NB don't use in chronic benzodiazepine user
lidocaine with epi	max 7 mg/kg SC	Local anesthetic	Not to be used in fingers, nose, toes, penis, ears
lidocaine w/o epi	max 5 mg/kg SC	Local anesthetic	
Polysporin®	apply to affected area bid-tid	Superficial infections	
morphine	15-30 mg PO q8-12h 0.1-0.2 mg/kg max 15 mg IV q4h	Mild to moderate acute/chronic pain Prescribed in combination with NSAIDs or acetaminophen	GI and constipation side effects DO NOT CRUSH, CUT or CHEW
Percocet 10/325®	1-2 tabs PO q6h prn	Moderate pain control	Oxycodone + acetaminophen Max 4 g acetaminophen daily
acetaminophen	325-650 mg PO q4-6h prn	Pain control	Max 4 g daily
Tylenol #3®	1-2 tabs PO q4-6h prn	Pain control	Max 4 g acetaminophen daily
Ibuprofen	200-800 mg PO tid prn max 1200 mg/d	Mild to moderate acute pain Analgesia and anti-inflammatory properties	
thiamine	Wernicke's encephalopathy: 100 mg IV/IM initially then 50-100 mg IM/IV OD/PO x 3d	To treat/prevent Wernicke's encephalopathy	Caution use in pregnancy
diazepam	anxiety: 2-10 mg PO tid/qid alcohol withdrawal: 10-20 mg PO/IV q1h titrated to signs/symptoms	Anxiety Alcohol withdrawal	
lorazepam	anxiety: 0.5-2 mg PO/IM/IV q6-8h status epilepticus: 4 mg IV repeat up to q5min	Anxiety Status epilepticus	
phenytoin	status epilepticus: see Table 13	Status epilepticus	Begin maintenance dose 12hr after loading dose Continuous ECG, BP monitoring mandatory
epinephrine	anaphylaxis: 0.1-0.5 mg IM; can repeat q10-15min	Anaphylaxis	Max 1 mg/dose

Table 33. Commonly Used Medications (continued)

Drug	Dosing Schedule	Indications	Comments
salbutamol	2 puffs inhaled q4-6h (4yrs) max 12 puffs/day	Asthma	Caution with cardiac abnormalities
ipratropium bromide	2-3 puffs inhaled tid-qid, max 12 puffs/day	Asthma	Contraindicated with peanut/soy allergy Caution with narrow-angle glaucoma
nitroglycerin	acute angina: 0.3-0.6 mg SL q5min, OR 5 µg/min IV increasing by 5-20 µg/min q3-5min	Angina Acute MI	Not to be used with other anti-hypertensives
ASA	325-650 mg PO q4h max 4g/day stroke/MI risk: 81-325 mg PO OD	Pain control Cardiac prevention	
β-blockers (metoprolol)	5 mg slow IV q5min x 3 if no contraindications	Acute MI	
enoxaparin	1 mg/kg SC BID	Acute MI	
insulin	bolus 5-10 U (0.2 U/kg) then 5-10 U (0.1 U/kg) per hour	Hyperglycemia	Monitor blood glucose levels Consider K replacement, also measure blood glucose levels before administration
glucose	0.5-1.0 g/kg (1-2 ml/kg) IV of D50W	Hypoglycemia/DKA	
furosemide (Lasix®)	CHF: 40-80 mg IV HTN: 10-40 mg PO BID	CHF HTN	Monitor for electrolyte imbalances
haloperidol	2.5-5.0 mg PO/IM initial effective dose 6-20 mg/day	Psychosis	Monitor with Parkinson's; results in CNS depression
naloxone	0.5-2 mg or 0.01-0.02 mg/kg initial bolus IV/IM/SL/SC or via ETT (2-2.5x IV dose), increase dose by 2 mg until response/max 10 mg	Comatose patient Opioid overdose Reversal in procedural sedation	
activated charcoal	30-100 g PO in 250 ml H ₂ O	Poisoning/overdose

ADH and **oxytocin** are synthesized by the hypothalamus. They are transported via neurons to the posterior pituitary and are subsequently secreted into the systemic circulation from this location.

GENERAL FUNCTION OF ORGANS

The Hypothalamic-Pituitary Axis

Information about cortical inputs, automatic function, environmental cues (light, temp) and peripheral hormonal feedback is synthesized at the coordinating centre of the endocrine system, the hypothalamus. The hypothalamus then sends signals to the pituitary to release hormones to affect the thyroid, adrenals, gonads, growth, milk production and water balance.

Anatomy ↔ Function

Hypothalamic hormones: small peptides, no binding protein → rapid degradation
High [] in pituitary-portal blood system
Low [] in peripheral circulation
Proximity of axis preserves the pulsatile output signals from the hypothalamic neurons.

Thyroid

Thyroid hormone is critical to 1) brain and somatic development in fetus and infants, 2) metabolic activity in adults, and 3) function of virtually every organ system.

Adrenal

Each gland, 6-8g, has 1) a cortex with 3 layers that act like independent organs (zona glomerulosa → aldosterone, fasciculata → cortisol, reticularis → androgen and estrogen precursors), and 2) a medulla that acts like a sympathetic ganglion to store/synthesize adrenaline and noradrenaline.

Gonads

Bifunctional: sex steroid synthesis and gamete production
Sex steroids controls sexuality and affect metabolic and brain functions

Parathyroid

Synthesize and secrete PTH, a principle regulator of ECF Ca, regulated by [Ca], [Mg] and 1,25(OH)₂D (active metabolite of Vit-D).

Pancreas

Endocrine islet cells produce insulin: oppose glucose production (glycogenolysis, gluconeogenesis), increase glucose uptake into muscle, liver and fat. Glucagon, epinephrine, cortisol, and GH are counter regulatory.

Basic Anatomy Review

Major Endocrine Organs

Figure 1. Endocrine System

Dyslipidemias

Definition

- metabolic disorders characterized by elevations of fasting plasma cholesterol, and/or triglycerides (TG), and/or low HDL

Overview of Lipid Transport

- lipoproteins are spherical complexes that consist of a lipid core surrounded by a shell of water-soluble proteins and phospholipids
- lipoproteins transport lipids within the body
- apolipoproteins serve as enzyme co-factors and stabilize the lipoprotein micelle

Table 1. Lipoproteins

Lipoprotein	Apolipoproteins	Function
Exogenous pathway		
Chylomicron	B-48, C, E, A-I, A-II, A-IV	• Transports dietary TG from gut to adipose tissue and muscle
Endogenous Pathway		
VLDL	B-100, C, E	• Transports hepatic synthesized TG from liver to adipose tissue and muscle
IDL	B-100, E	• Product of hydrolysis of VLDL by lipoprotein lipase resulting in depletion of TG core • Enriched in cholesterol esters
LDL	B-100	• Formed by further removal of residual TG from IDL core by hepatic lipase resulting in greater enriched particles with cholesterol esters • Transports cholesterol from liver to peripheral tissues (gonads, adrenals)
HDL	A-I, A-II, C, E	• Transports cholesterol from peripheral tissues to liver • Acts as a reservoir for apolipoproteins

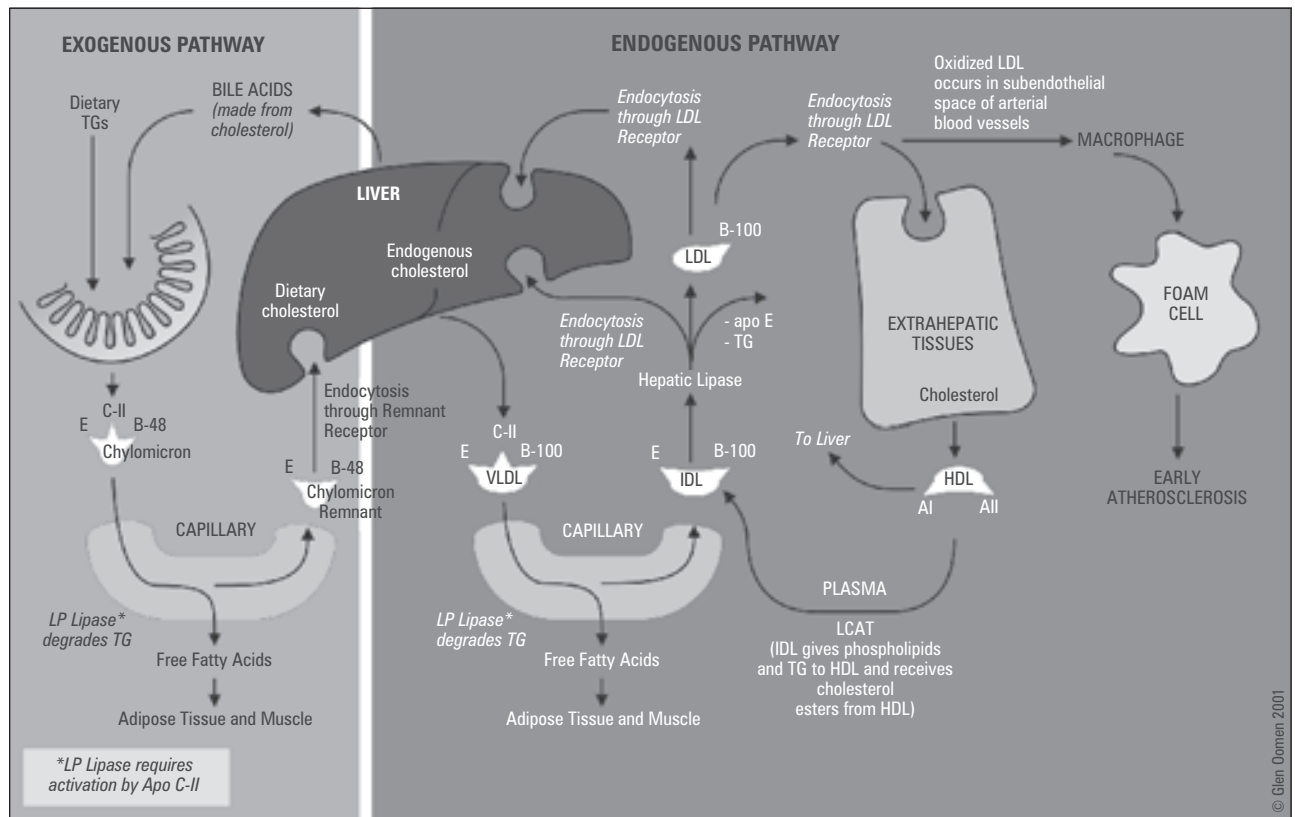

Figure 2. Exogenous and Endogenous Biosynthetic Lipid Pathways

Hypercholesterolemia

PRIMARY HYPERCHOLESTEROLEMIA

Table 2. The Primary Hypercholesterolemias

Hypercholesterolemia	Etiology/Pathophysiology	Labs	Clinical Presentation	Treatment
Familial Hypercholesterolemia (Frederickson Type IIa)	<ul style="list-style-type: none"> 1/500 in US population Autosomal dominant with high penetrance Defect in the normal LDL receptor on cell membranes 	↑ LDL ↑ TC	<ul style="list-style-type: none"> Tendinous xanthomatosis (achilles, patellar, and extensor tendons of hand) Arcus corneae Xanthelasma Heterozygotes: premature CAD, 50% risk of MI in men by age 30 Homozygotes: manifest CAD and other vascular disease early in childhood and can be fatal (<20 y) if untreated 	<ul style="list-style-type: none"> Heterozygotes: improvement of LDL with dual combination of HMG CoA reductase inhibitors, niacin, or bile acid sequestrants Homozygotes: partial control with portacaval shunt or LDL apheresis in conjunction with niacin; large dose atorvastatin is modestly effective
Polygenic Hypercholesterolemia	<ul style="list-style-type: none"> Most common Few mild inherited defects in cholesterol metabolism 	↑ TC ↑ LDL	<ul style="list-style-type: none"> Asymptomatic until vascular disease develops No xanthomata 	<ul style="list-style-type: none"> HMG CoA reductase inhibitors, bile acid sequestrant, niacin

SECONDARY HYPERCHOLESTEROLEMIA

Etiology

- diet
- anorexia nervosa
- hypothyroidism
- cholestatic liver disease (e.g. primary biliary cirrhosis)
- nephrotic disease
- monoclonal gammopathy
- drugs (cyclosporin, diuretics, carbamazepine)

Hypertriglyceridemia (Elevated TG)

PRIMARY HYPERTRIGLYCERIDEMIA

Table 3. The Primary Hypertriglyceridemias

Hypertriglyceridemia	Etiology/Pathophysiology	Labs	Clinical Presentation	Treatment
Familial Lipoprotein Lipase deficiency (Frederickson Type I)	<ul style="list-style-type: none"> Autosomal recessive deficiency of lipoprotein lipase or its cofactor 	↑ TG ↑ Chylomicrons Moderate ↑ in VLDL	<ul style="list-style-type: none"> Hepatosplenomegaly Splenic infarct Anemia, granulocytopenia, thrombocytopenia 2° to hypersplenism Pancreatitis Lipemia retinalis Eruptive xanthomata 	<ul style="list-style-type: none"> Decrease dietary fat intake to <10% of total calories
Familial Hypertriglyceridemia (Frederickson Type IV)	<ul style="list-style-type: none"> Several genetic defects resulting in ↑ hepatic VLDL synthesis or ↓ removal of VLDL 	↑ TG ↑ VLDL	<ul style="list-style-type: none"> Eruptive xanthomata Lipemia retinalis Recurrent epigastric pain Premature CAD Early adulthood develop syndrome of obesity, hypertriglyceridemia, hyperinsulinemia and hyperuricemia 	<ul style="list-style-type: none"> Decrease dietary fat intake Abstain from EtOH Fibrates or niacin

SECONDARY HYPERTRIGLYCERIDEMIA

Etiology

- obesity/metabolic syndrome
- alcohol
- diabetes mellitus
- drugs (corticosteroids, estrogen, hydrochlorothiazide, retinoic acid, beta-blockers without intrinsic sympathomimetic action (ISA), anti-retroviral drugs)
- chronic liver failure
- hepatitis
- polyclonal and monoclonal hypergammaglobulinemia
- glycogen storage disease
- hypothyroidism
- hypopituitarism
- acromegaly

Combined Hyperlipidemia

Table 4. Primary Combined Hyperlipidemias

Hyperlipidemia	Etiology/Pathophysiology	Labs	Clinical Presentation	Treatment
Familial Combined Hyperlipidemia (Frederickson Type IIb)	<ul style="list-style-type: none"> Most common form of hyperlipidemia Over-population of VLDL and associated ↑ LDL 2° to excess hepatic synthesis of apolipoprotein B Autosomal dominant 	↑ TC + TG ↑ VLDL ↑ LDL	<ul style="list-style-type: none"> Xanthelasma CAD and other vascular disease 	<ul style="list-style-type: none"> Weight reduction Decrease fat, cholesterol, and EtOH in diet Niacin, fibrates HMG CoA reductase inhibitors
Dysbetalipoproteinemia (Frederickson Type III)	<ul style="list-style-type: none"> Abnormal apolipoprotein E 	↑ TC + TG ↑ VLDL ↑ IDL	<ul style="list-style-type: none"> Tuberous, eruptive, planar xanthomata Impaired glucose tolerance CAD and PVD 	<ul style="list-style-type: none"> Weight reduction Decrease fat, cholesterol, and EtOH in diet Niacin, fibrates HMG CoA reductase inhibitors

Dyslipidemia and the Risk for CAD

- increased LDL is a major risk factor for atherosclerosis and CAD
- increased HDL is associated with decreased cardiovascular disease and mortality
- hypertriglyceridemia is an independent risk factor for CAD in people with diabetes mellitus and in postmenopausal women

Screening

- screen men over age 40, women over age 50 or postmenopausal
- if following risk factors present, screen at any age:
 - diabetes
 - cigarette smoking
 - hypertension (sBP >140, dBP >90)
 - obesity (BMI >27 kg/m²)
 - family history of premature coronary artery disease
 - clinical signs of hyperlipidemia (xanthelasma, xanthoma, arcus corneae)
 - evidence of atherosclerosis
 - rheumatoid arthritis, systemic lupus erythematosus, psoriasis
 - HIV infection on highly active antiretroviral therapy
 - chronic kidney disease (estimated GFR <60 ml/min/1.73 m²)
 - erectile dysfunction
- screen children with a family history of hypercholesterolemia or chylomicronemia

Factors Affecting Risk Assessment

- metabolic syndrome
- apolipoprotein B (apoB):
 - each atherogenic particle [VLDL, IDL, LDL and lipoprotein(a)] contains one molecule of apoB
 - serum [apoB] reflects the total number of particles and may be useful in assessing cardiovascular risk and adequacy of treatment in high risk patients and those with metabolic syndrome

Table 5. Optimal Target Levels of Apolipoprotein B by Risk Group*

	High	Moderate	Low
Target apoB levels (g/L)	<0.85	<1.05	<1.2

*Risk Stratification by Framingham Risk Score. See *Family Medicine*, FM7

- C-reactive protein (CRP) levels:
 - highly sensitive acute phase reactant
 - may be clinically useful in identifying those at a higher risk of cardiovascular disease than predicted by the global risk assessment

Treatment of Dyslipidemias

Approach to Treatment

For clinical guidelines see *Can J Cardiol* 2009; 25(10):567-579.

- estimate 10-year risk of CAD using Framingham model (see *Family Medicine*, FM6)
- establish treatment targets according to level of risk (see Table 6)

Table 6. Target LDL by Risk Group

Level of Risk	10-year Risk of CAD	Target LDL (mmol/L)	(mg/dL)	Target TC/HDL	Alternate
High	≥20%	<2.0	<78 mg/dL	<4	apoB <0.80 g/L
Moderate	10-19%	<3.5	<136.5 mg/dL	<5	apoB <0.80 g/L
Low	<10%	<5.0	<195 mg/dL	<6	

Table 7. Treatment of Hypercholesterolemia and Hypertriglyceridemia

Treatment of Hypercholesterolemia	Treatment of Hypertriglyceridemia
<ul style="list-style-type: none"> • Conservative: 4-6 month trial unless high risk group, in which case medical treatment should start immediately <ul style="list-style-type: none"> ▪ Diet <ul style="list-style-type: none"> • Decrease fat: <30% calories • Decrease saturated fat: <10% calories • Decrease cholesterol: <300 mg/day • Increase fibre: >25-35 g/day ▪ Decrease alcohol intake ▪ Smoking cessation ▪ Aerobic exercise: 30-60 minutes/day, 4-7 times/week ▪ Weight loss: target body mass index (BMI) <25 • Medical <ul style="list-style-type: none"> ▪ HMG-CoA reductase inhibitors, ezetimibe, bile acid sequestrants, niacin (see <i>Common Medications</i> section) 	<ul style="list-style-type: none"> • Conservative: 4-6 month trial <ul style="list-style-type: none"> ▪ Diet <ul style="list-style-type: none"> • Decrease fat and simple carbohydrates • Increase omega-3 fatty acids ▪ Control blood sugars ▪ Decrease alcohol intake ▪ Smoking cessation ▪ Aerobic exercise: 30-60 minutes/day, 4-7 times/week ▪ Target body mass index (BMI) <25 • Medical: fibrates, niacin (see <i>Common Medications</i> section) <ul style="list-style-type: none"> ▪ Indications: <ul style="list-style-type: none"> • Failed conservative measures • TG >10 mmol/L (885 mg/dL) to prevent pancreatitis • Combined hyperlipidemia

Non-traditional Positive Risk Factors

- ↑ Apo-B (apolipoprotein B)
- ↓ Apo A-1 (apolipoprotein A-1)
- Small dense LDL
- ↑ fibrinogen
- ↑ PAI-1
- ↑ IL-6 (interleukin 6)
- ↑ TNF (tumour necrosis factor)
- ↑ CRP (c-reactive protein)
- ↓ adiponectin
- ↑ homocysteine

Treatment Effect

Each 1.0 mmol/L decrease in LDL corresponds to 20-25% relative risk reduction in cardiovascular disease.

For Statin Follow-Up

- Lipids and liver enzymes every 4-6 months or if patient complains of jaundice, RUQ pain, dark urine
- CK at baseline and if patient complains of myalgia
- D/C statin if CK >10x upper limit of normal

Intensive Lipid Lowering in CAD: TNT

NEJM 2005; 352(14):1425-35

Study: Multicentre, randomized, double-blinded trial with median follow-up of 4.9 years.

Patients: 10,001 patients with CAD and LDLC <3.4.

Intervention: 80 mg versus 10 mg atorvastatin daily.

Main outcomes: Death from CAD, MI, cardiac arrest, or stroke.

Results: A primary event occurred in 8.7% of the patients receiving intensive therapy, compared to 10.9% of patients receiving standard therapy (RR 0.78, p<0.001). There was no difference in overall mortality. Incidence of persistent transaminase elevations was higher in the intensive therapy group (1.2% versus 0.2%, p<0.001).

Conclusion: Intensive statin therapy is associated with lower rates of CAD events than standard therapy, but also a higher rate of transaminase elevation.

Simvastatin to Lower CAD Risk – The Heart Protection Study

Lancet 2002; 360:7-22

Study: Randomized, double-blind, placebo-controlled trial (median follow-up 5.0 years).

Patients: 20,536 patients with coronary disease, other occlusive arterial disease, or diabetes (aged 40-80 years) who had a total cholesterol level of 3.5mmol/L.

Intervention: Simvastatin 40 mg/day or placebo.

Main Outcomes: Mortality, fatal or non-fatal vascular events.

Results: The use of simvastatin significantly decreased total mortality (12.9 vs. 14.7, p=0.0003) and the first event rate of any cardiovascular event by 25% (p<0.0001).

Conclusion: Treatment with simvastatin improved survival and cardiovascular outcomes in high-risk CAD patients.

Disorders of Glucose Metabolism

Overview of Glucose Regulation

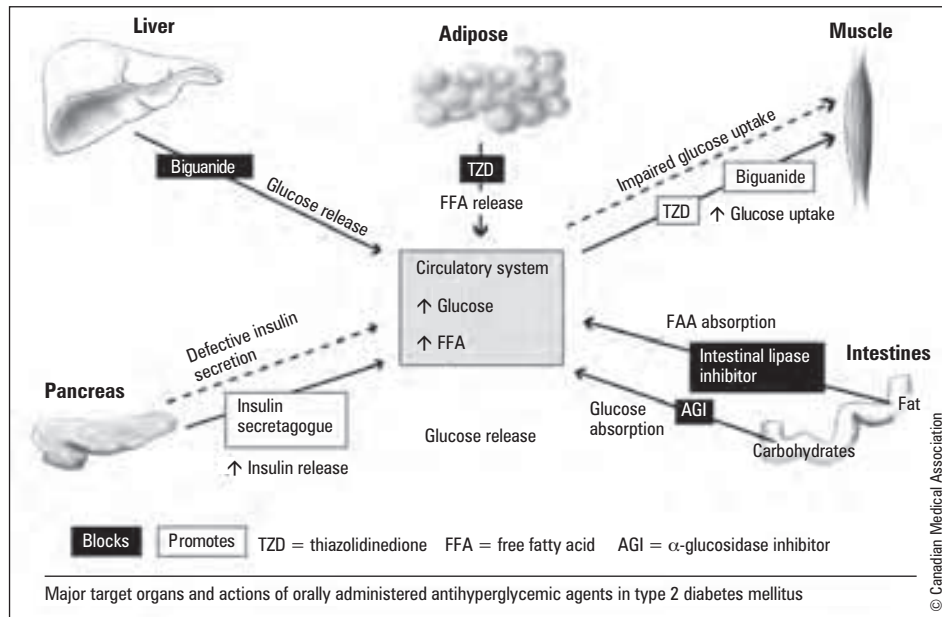

Figure 3. Antihyperglycemic Agents

Pre-Diabetes (Impaired Glucose Tolerance/ Impaired Fasting Glucose)

- 1-5% per year go on to develop diabetes mellitus
- 50-80% revert to normal glucose tolerance
- weight loss may improve glucose tolerance
- increased risk of developing macrovascular complications
- lifestyle modifications decrease progression to DM by 51%

Diagnostic Criteria

- impaired fasting glucose (IFG): fasting blood glucose (FBG) 6.1-6.9 mmol/L (110-125 mg/dL)
- impaired glucose tolerance (IGT): 2h 75 g oral glucose tolerance test (OGTT) 7.8-11.0 mmol/L (140-200 mg/dL)

Diabetes Mellitus (DM)

Definition

- syndrome of disordered metabolism and inappropriate hyperglycemia secondary to an absolute/ relative deficiency of insulin, or a reduction in biological effectiveness of insulin, or both

Diagnostic Criteria

- any one of the following is diagnostic:
 - presence of classic symptoms of DM (polyuria, polydipsia, polyphagia, weight loss, blurry vision, nocturia, ketonuria) PLUS random blood glucose (BG) ≥ 11.1 mmol/L (200 mg/dL)
 - FBG ≥ 7.0 mmol/L (126 mg/dL)
 - 2h 75 g OGTT ≥ 11.1 mmol/L (200 mg/dL)
 - HbA1C $\geq 6.5\%$ (American Diabetes Association Guidelines, Jan 2010)

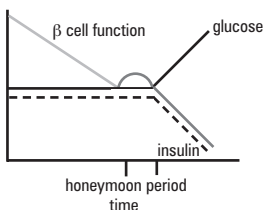

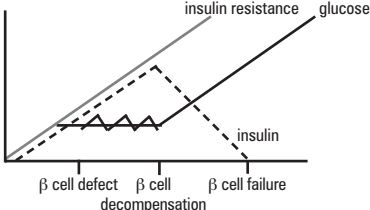

Etiology and Pathophysiology

Table 8. Etiologic Classification of Diabetes Mellitus

- I. **Type 1 diabetes** (immune-mediated beta cell destruction, usually leading to absolute insulin deficiency)
- II. **Type 2 diabetes** (ranges from predominantly insulin resistance with relative insulin deficiency to a predominantly insulin secretory defect with insulin resistance 2° to beta cell dysfunction)
- III. **Other specific causes of diabetes:**
 - a. Genetic defects of beta cell function (e.g. MODY – Maturity-Onset Diabetes of the Young) or insulin action
 - b. Diseases of the exocrine pancreas:
 - Pancreatitis, pancreatectomy, neoplasia, cystic fibrosis, hemochromatosis (“bronze diabetes”)
 - c. Endocrinopathies:
 - Acromegaly, Cushing’s syndrome, glucagonoma, pheochromocytoma, hyperthyroidism
 - d. Drug-induced:
 - Glucocorticoids, thyroid hormone, beta-adrenergic agonists, thiazides, phenytoin, clozapine
 - e. Infections:
 - Congenital rubella, CMV, coxsackie
 - f. Genetic syndromes associated with diabetes:
 - Down’s syndrome, Klinefelter’s syndrome, Turner’s syndrome

IV. Gestational Diabetes Mellitus

Table 9. Comparison of Type 1 and Type 2 Diabetes Mellitus

	Type 1	Type 2
Onset	<ul style="list-style-type: none"> Usually <30 years of age 	<ul style="list-style-type: none"> Usually >40 years of age Increasing incidence in pediatric population 2° to obesity
Epidemiology	<ul style="list-style-type: none"> More common in Caucasians Rare in Asians, Hispanics, Aboriginals, and Blacks Accounts for 5-10% of all DM 	<ul style="list-style-type: none"> More common in Blacks, Hispanics, Aboriginals, Asians Accounts for >90% of all DM
Etiology	<ul style="list-style-type: none"> Autoimmune 	<ul style="list-style-type: none"> Complex and multifactorial
Genetics	<ul style="list-style-type: none"> Monozygotic twin concordance is 30-40% Associated with HLA class II DR3 and DR4, with either allele present in up to 95% of Type 1 DM Certain DQ alleles also confer a risk 	<ul style="list-style-type: none"> Greater heritability than Type 1 DM Monozygotic twin concordance is 70-90% Polygenic Non-HLA associated
Pathophysiology	<ul style="list-style-type: none"> Synergistic effects of genetic, immune, and environmental factors that cause beta cell destruction resulting in impaired insulin secretion Autoimmune process is believed to be triggered by environmental factors (e.g. viruses, bovine milk protein, urea compounds) Pancreatic cells are infiltrated with lymphocytes resulting in islet cell destruction 80% of beta cell mass is destroyed before features of diabetes present 	<ul style="list-style-type: none"> Impaired insulin secretion, peripheral insulin resistance (likely due to receptor and post receptor abnormality), and excess hepatic glucose production
Natural history	 <ul style="list-style-type: none"> After initial presentation, honeymoon period often occurs where glycemic control can be achieved with little or no insulin treatment as residual cells are still able to produce insulin Once these cells are destroyed, there is complete insulin deficiency 	 <ul style="list-style-type: none"> Early on, glucose tolerance remains normal despite insulin resistance as beta cells compensate with increased insulin production As insulin resistance and compensatory hyperinsulinism continue, the beta cells are unable to maintain the hyperinsulinemic state which results in glucose intolerance and diabetes
Circulating autoantibodies	<ul style="list-style-type: none"> Islet cell Ab present in up to 60-85% Most common islet cell Ab is against glutamic acid decarboxylase (GAD) Up to 60% have Ab against insulin 	<ul style="list-style-type: none"> <10%

Three-year Efficacy of Complex Insulin Regimens in Type 2 Diabetes: 4T Trial

NEJM 2009; 361:1736-47

Study: Randomized, unblinded trial with 3 years of follow-up.

Population: 708 patients with type 2 diabetes, not on insulin or thiazolidinedione therapy, on maximal metformin and sulfonylurea therapy.

Intervention: Thrice-daily prandial insulin aspart, versus twice-daily biphasic insulin aspart, versus once-daily basal insulin detemir. Sulfonylurea therapy was replaced with a secondary insulin regime specific to each arm if there was persistent hyperglycemia.

Primary Outcome: 3-year hemoglobin HgA1c.

Results: Significant difference in rates of patient withdrawal from the study: 5.1% biphasic, 11.7% prandial, 8.5% basal regimens ($p=0.04$). There were no significant differences in median HbA1C levels between all three arms from year 1 to 3. A smaller proportion of patients reached HbA1C <6.5% or <7.0% in the biphasic arm. The basal arm had least weight gain and least weight circumference increase, but highest rate of secondary insulin requirement. The basal arm had fewest severe hypoglycemic events per patient year, while the biphasic had the most serious adverse effects.

Conclusion: Basal insulin regime provides the best glycemic control over a 3-year study; with better HbA1C control, fewer hypoglycemic events, and less weight gain.

Blood Glucose Control in Type 2 DM – UKPDS 33

Lancet 1998; 352:837-53

Study: Randomized controlled trial (mean follow-up 10 years).

Patients: 3867 patients with newly diagnosed Type 2 DM (mean age 53 y, 61% men, 81% white, mean fasting plasma glucose (FPG) 6.1-15.0 mmol/L). Exclusions included severe cardiovascular disease, renal disease, retinopathy, and others.

Intervention: Intensive treatment with a sulfonylurea or insulin (target FPG <6 mmol/L) vs. conventional treatment with diet alone (target FPG <15 mmol/L without hyperglycemic symptoms).

Main outcomes: Diabetes-related endpoints (MI, angina, heart failure, stroke, renal failure, amputation, retinopathy, blindness, death from hyperglycemia or hypoglycemia), diabetes-related death, and all-cause mortality.

Results: Patients allocated to intensive treatment had lower median HbA1C levels ($p<0.001$).

Outcome	RRR % (p value)
Diabetes-related endpoint	12 (0.029)
Diabetes-related death	10 (0.34)
All-cause mortality	6 (0.44)

Patients allocated to intensive therapy had more hypoglycemic episodes and greater weight gain.

Conclusion: Intensive blood glucose control reduces microvascular, but not macrovascular complications in Type 2 DM.

Intensive Blood Glucose Control and Vascular Outcomes in Patients with Type 2 DM: The ADVANCE Trial

NEJM 2008; 358:2560-72

Study: Multicentre, randomized, controlled trial.

Patients: 11,140 patients with Type 2 DM and risk factors for vascular disease.

Intervention: Intensive glucose control (HbA1C $\leq 6.5\%$) versus standard glucose control (determined by local guidelines).

Primary Outcomes: Composite macrovascular (death from cardiovascular cause, nonfatal MI, nonfatal stroke) and microvascular events (nephropathy, retinopathy).

Results: The incidence of the composite primary outcome was lower in the intensive glucose control arm. Individually, there was no difference in macrovascular events or all-cause mortality, but there was a lower incidence of microvascular events, nephropathy, new-onset microalbuminuria, and macroalbuminuria in the intensive glucose control arm. All-cause hospitalization, hypoglycemia-related hospitalization, and severe hypoglycemia occurred more frequently in the intensive glucose control arm.

Conclusions: Intensive glucose control can improve microvascular outcomes, especially nephropathy, but does not impact macrovascular events or mortality, and has greater incidence of hypoglycemic adverse events in patients with Type 2 DM.

Table 9. Comparison of Type 1 and Type 2 Diabetes Mellitus (continued)

	Type 1	Type 2
Risk Factors	<ul style="list-style-type: none"> Personal history of other autoimmune diseases including Graves', myasthenia gravis, autoimmune thyroid disease, celiac disease and pernicious anemia 	<ul style="list-style-type: none"> Age >40 y Abdominal obesity/overweight First-degree relative with DM Race/ethnicity (Black, Aboriginal, Hispanic, Asian-American, Pacific Islander) History of IGT or IFG HTN Dyslipidemia PCOS Gestational DM Schizophrenia Fatty liver Hyperuricemia
Body Habitus	<ul style="list-style-type: none"> Normal to wasted 	<ul style="list-style-type: none"> Typically overweight with increased central obesity
Treatment	<ul style="list-style-type: none"> Insulin 	<ul style="list-style-type: none"> Lifestyle modification Oral antihyperglycemic agents Insulin therapy

Screening	<ul style="list-style-type: none"> Subclinical prodrome can be detected in first and second-degree relatives of those with Type 1 DM by the presence of pancreatic islet autoantibodies 	<ul style="list-style-type: none"> Screen individuals with risk factors (see above)

Treatment of Diabetes

Glycemic Targets

- HbA1C reflects glycemic control over 3 months and is a measure of patient's long-term diabetes control
- American Diabetes Association (ADA) suggests HbA1C $<7.0\%$, whereas American Association of Clinical Endocrinologists (AACE) suggests $<6.5\%$
- Canadian Diabetes Association (CDA) guidelines recommend target $<7.0\%$
- there may be harm associated with strategy to target HbA1C $<6.0\%$ in certain patients with Type 2 DM (see EBM box re: ACCORD trial, E9)

Canadian Diabetes Guidelines 2008

	Target	Optimal
HbA1C	$<7.0\%$	$<6.0\%$
Fasting plasma glucose	4-7 mmol/L (72-126 mg/dL)	4-6 mmol/L (72-108 mg/dL)
2h post prandial glucose	5-10 mmol/L (90-180 mg/dL)	5-8 mmol/L (90-144 mg/dL)
Lipids	As per high or moderate risk group	Same
Blood pressure	$<130/80$	Same

A target A1C of 6.5% may be considered in some patients with type 2 diabetes but this should be balanced against the risk of hypoglycemia.

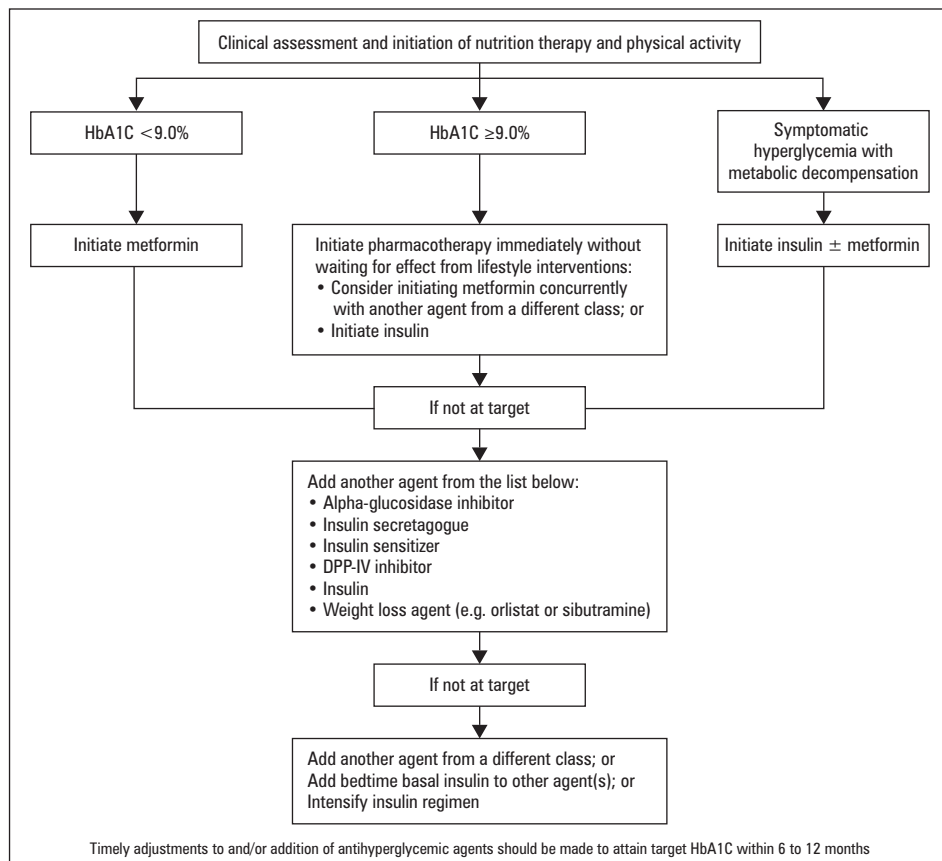

Figure 4. Approach to Treatment of Hyperglycemia in Type 2 DM

Adapted from *Can J Diabetes* 2008; 32(suppl1):S56

Diet

- daily carbohydrate intake 50-55% of energy, protein 15-20% of energy and fat <30% of energy
- intake of both saturated and polyunsaturated fats <10% of total calories each
- limit sodium, alcohol and caffeine intake
- Type 1: carbohydrate counting is used to titrate insulin regimen
- Type 2: weight reduction

Lifestyle

- regular physical exercise to improve insulin sensitivity, lower lipid concentrations and control blood pressure
- smoking cessation

Medical Treatment: Oral Antihyperglycemic Agents (Type 2 DM)

- initiate oral antihyperglycemic therapy within 2-3 months if lifestyle management does not result in glycemic control
- if HbA1C >9.0%, initiate pharmacologic therapy immediately and consider combination oral therapy or insulin immediately
- see *Common Medications*, E51 for details on antihyperglycemic agents

Medical Treatment: Insulin (Figure 5)

- used for Type 1 DM, may be used in Type 2 DM at any point in treatment
- routes of administration: subcutaneous injections, continuous subcutaneous insulin infusion pump, IV infusion (regular insulin only)
- bolus insulins: short-acting (Humulin R, Novolin Toronto), rapid-acting analogue (Apidra, Humalog, Novorapid)
- basal insulins: intermediate-acting (Humulin N, Novolin NPH), long-acting analogue (Lantus, Levemir)
- premixed insulins (%R and %NPH) 10/90, 20/80, 30/70, 40/60, 50/50; analogues (Humalog Mix25®, Humalog Mix50®, Novomix 30®)
- estimated total daily insulin requirement: 0.5-0.7 units/kg

Table 10. Available Insulin Formulations

Insulin Type (trade name)	Onset	Peak	Duration
Prandial (bolus) insulins			
Rapid-acting insulin analogues			
• Insulin aspart (NovoRapid)	10-15 min	1-1.5 h	3-5 h
• Insulin lispro (Humalog)	10-15 min	1-2 h	3.5-4.75 h
• Insulin glulisine (Apidra)	10-15 min	1-1.5 h	3-5 h
Short-acting insulins			
• Humulin R	30 min	2-3 h	6.5 h
• Novolin Toronto			
Inhaled insulin	10-20 min	2 h	6 h
Basal insulins			
Intermediate-acting			
• Humulin N	1-3 h	5-8 h	Up to 18 h
• Novolin NPH			
Long-acting basal insulin analogues			
Insulin detemir (Levemir)	90 min	Not applicable	Up to 24 h (glargine 24 h, detemir 16-24 h)
Insulin glargine (Lantus)			
Pre-mixed insulins			
Premixed regular insulin – NPH			
• Humulin 30/70	A single vial or cartridge contains a fixed ratio of insulin (% of rapid acting or short-acting insulin to % of intermediate-acting insulin)		
• Novolin 30/70, 40/60, 50/50			
Premixed insulin analogues			
• Biphasic insulin aspart (NovoMix 30)			
• Insulin lispro/lispro protamine			
• Humalog Mix25 and Mix50			

Effects of Intensive Glucose Lowering in Type 2 DM: The ACCORD Trial

NEJM 2008; 358:2545-59

Study: Multicentre, randomized, controlled trial.

Patients: 10,251 patients (mean age 62.2) with Type 2 DM, and cardiovascular risk factors.

Intervention: Intensive therapy targeting a HbA1C level of less than 6.0% or standard therapy targeting 7.0 to 7.9%.

Outcomes: First occurrence of nonfatal MI, nonfatal stroke, or death from CV causes.

Results: The intensive therapy arm was stopped early (3.5 yrs vs. 5.6 yrs planned) due to evidence of increased mortality. There was no difference in primary outcome for either study arm. There was a significant increase in all-cause mortality, CV-cause mortality, nonfatal MI, and all congestive heart failure in the intensive therapy group. There were increased rates of all hypoglycemic events, any nonhypoglycemic serious adverse event, fluid retention, and weight gain >10 kg, but lower systolic and diastolic blood pressure in the intensive therapy group. There was an increased incidence of elevated ALT (>3 times upper limit) and ACE drug use in the standard therapy group.

Conclusions: Intensive glucose lowering therapy in Type 2 DM does not improve clinic outcomes and actually increases the risk of mortality with more adverse events compared to standard therapy. Additional research is required to discern the cause.

Effects of Intensive Blood Pressure Control in Type 2 DM: The ACCORD Trial

NEJM 2010; 362:1575-85

Study: RCT, unblinded with 4.7 years of mean follow-up.

Population: 4,733 patients with type 2 diabetes, risk factors for cardiovascular (CV) disease, systolic blood pressure (sBP) between 130-180 mmHg.

Intervention: sBP control less than 120 mmHg (intensive) or 140 mmHg (standard).

Primary Outcomes: Major CV event (composite nonfatal myocardial infarction, nonfatal stroke, or CV-related death).

Results: Mean number of medications at 1 year for intensive therapy was 3.4 (95% CI, 3.4-3.5) versus 2.1 (95% CI, 2.1-2.2) for standard therapy. There was a significant increase in all serious adverse events in the intensive treatment arm (3.3% vs. 1.27%, $p < 0.001$); especially bradycardia or arrhythmia (0.5% vs. 0.13%, $p = 0.02$) and hyperkalemia (0.4% vs. 0.04%, $p = 0.01$). There was no significant difference in primary outcomes in the two study arms, or all-cause mortality. There was a significant reduction in any stroke (0.32%/yr vs. 0.53%/yr, $p = 0.01$) and nonfatal stroke incidences (0.30%/yr vs. 0.47%/yr, $p = 0.03$) in the intensive therapy arm.

Conclusions: Intensive BP lowering to less than 120 mmHg versus 140 mmHg in patients with Type 2 DM and CV risk factors does not reduce major CV event risk reduction except for stroke events.

Effects of Combination Lipid Therapy in Type 2 DM: the ACCORD Trial

NEJM 2010; 362(18):1563-74

Study: RCT, double-blinded trial with 4.7 years of mean follow-up.

Population: 5,518 patients with type 2 diabetes.

Intervention: Statin with or without fibrate therapy.

Primary Outcome: Major cardiovascular (CV) event (composite nonfatal myocardial infarction, nonfatal stroke, or CV-related death).

Results: No significant differences primary outcome between the two arms. No difference in all myocardial infarction, all stroke, or all-cause mortality between study arms.

Conclusions: The addition of fibrate therapy to statin therapy in patients with Type 2 DM does not reduce major CV event risk.

**DPP-IV Inhibitors**

- Newer antihyperglycemic agents that inhibit the degradation of endogenous incretin hormones like GLP-1
- Stimulate insulin secretion, inhibit glucagon release from the pancreas and delay gastric emptying

Figure 5. Duration of Activity of Different Insulins

Insulin Regimens

1. Oral agent + basal insulin (NPH, detemir, glargine) (Type 2 only)
 - start with 10 units qhs, titrate up until FBG <7.0 mmol/L (126 mg/dL)
 - continue metformin and/or insulin secretagogue
2. Twice daily injections with premixed insulin
 - insulin mixture used depends on the distribution of carbohydrates in meals but usually start with 30/70
 - estimate total daily insulin requirement then split dose into 2/3 in AM and 1/3 before supper
 - AM bolus targets pre-lunch BG and AM basal targets pre-supper BG
 - PM bolus targets bedtime BG and PM basal targets FBG
 - continue metformin and discontinue secretagogue with this regimen
 - ♦ advantages: one type of insulin, 2 injections
 - ♦ disadvantages: requires rigid meal timing and carbohydrate content; limited ability to respond to increased or decreased BG (i.e. serum glucose before breakfast next day)
3. Basal-Bolus therapy [multiple daily injections (MDI)]
 - estimate total daily insulin requirement then take 20% of this daily dose before breakfast, lunch, and dinner using regular, aspart, glulisine or lispro (total 60%)
 - the remaining 40% is given as NPH, glargine or detemir at bedtime
 - continue metformin and discontinue secretagogue with this regimen
 - ♦ advantages: flexible meal timing and carbohydrate content, ability to respond to increased or decreased BG, or planned exercise
 - ♦ disadvantages: multiple injections

Table 11. Titrating Insulin Doses

Insulin Regime	Morning Blood Glucose	Lunch Blood Glucose	Dinner Blood Glucose	Bedtime Blood Glucose	Adjustments*
Twice Daily/MDI	Increased				Increase Evening I/L
Twice Daily/MDI		Increased			Increase Morning R/S
Twice Daily			Increased		Increase Morning I/L
MDI			Increased		Increase Lunch R/S
Twice Daily/MDI				Increased	Increase Evening R/S

* R=rapid acting, S=short-acting insulin, I= Intermediate Acting, L=Long-acting

Variable Insulin Dose Schedule ("Sliding/Supplemental/Correction Scale")

- patient takes usual doses of basal insulin but varies doses of bolus insulin based on BG reading at time of dose
- use baseline bolus insulin dose when within BG target range; add or subtract units when above or below target
- commonly used in hospital or in perioperative management of diabetes
- construction of a sliding scale for a patient on anti-hyperglycemics:
 - Correction Factor (CF) = 100/Total Daily Dose of insulin (TDD)
 - BS <4: call MD and give 15 g carbohydrates
 - BS between 4 to (7 + CF): no additional insulin
 - BS between (7 + CF) to (7 + 2CF): give one unit
 - BS between (7 + 2CF) to (7 + 3CF): give two units

Insulin Pump Therapy

- external battery-operated device provides continuous basal dose of rapid-acting insulin analogue (aspart, glulisine or lispro) through small subcutaneous catheter
- at meals, patient programs pump to deliver insulin bolus
- provides improved quality of life and flexibility
- risk of DKA if pump is inadvertently disconnected

Calculating Average Blood Sugar from HbA1C

- Average blood sugar = (HbA1C x 2) - 4

Conversion chart adapted from Nathan DM et al. The clinical information value of a glycosylated hemoglobin assay. *NEJM* 1984; 310:341-6

Acute Complications

Table 12. Acute Complications of Diabetes Mellitus: Hyperglycemic Comatose States

	Diabetic Ketoacidosis (DKA)	Hyperglycemic Hyperosmolar Nonketotic State (HONK)
Pathophysiology	<ul style="list-style-type: none"> Usually occurs in Type 1 DM Insulin deficiency with ↑ counterregulatory hormones (glucagon, cortisol, catecholamines, GH) Can occur with lack of insulin (noncompliance, poor dosage, 1st presentation) or increased stress (surgery, infection, exercise) Unrestricted hepatic glucose production → hyperglycemia → osmotic diuresis → dehydration and electrolyte disturbance → ↓ Na (pseudohyponatremia) Fat mobilization → ↑ FFA → ketoacids → metabolic acidosis Severe hyperglycemia exceeds the renal threshold for glucose and ketone reabsorption → glucosuria and ketonuria Total body K depletion but serum K may be normal or elevated 2° to shift from ICF to ECF due to lack of insulin, ↑ plasma osmolality Total body PO₄ depletion 	<ul style="list-style-type: none"> Occurs in Type 2 DM Often precipitated by sepsis, stroke, MI, CHF, renal failure, trauma, drugs (glucocorticoids, immunosuppressants, phenytoin, diuretics), dialysis, recent surgery, burns Partial or relative insulin deficiency decreases glucose utilization in muscle, fat, and liver while inducing hyperglucagonemia and hepatic glucose production Presence of a small amount of insulin prevents the development of ketosis by inhibiting lipolysis Characterized by hyperglycemia, hyperosmolality, and dehydration without ketosis More severe dehydration compared to DKA due to more gradual onset and ↑ duration of metabolic decompensation plus impaired fluid intake which is common in bedridden or elderly Volume contraction → renal insufficiency → ↑ hyperglycemia, ↑ osmolality → shift of fluid from neurons to ECF → mental obtundation and coma
Clinical Features	<ul style="list-style-type: none"> Polyuria, polydipsia, polyphagia with marked fatigue, nausea, vomiting Dehydration (orthostatic changes) LOC may be ↓ with high serum osmolality (osm >330 mmol/L) Abdominal pain Fruity smelling breath Kussmaul's respiration 	<ul style="list-style-type: none"> Onset is insidious → preceded by weakness, polyuria, polydipsia History of decreased fluid intake History of ingesting large amounts of glucose containing fluids Dehydration (orthostatic changes) ↓ LOC → lethargy, confusion, comatose Kussmaul's respiration is absent unless the underlying precipitant has also caused a metabolic acidosis
Serum	<ul style="list-style-type: none"> ↑ BG (11-55 mmol/L, 198-990 mg/dL), ↓ Na (spurious 2° to hyperglycemia → for every ↑ in BG by 10 mmol/L (180 mg/dL) there is a ↓ in Na by 3 mmol/L) Normal or ↑ K, ↓ HCO₃, ↑ BUN, ↑ Cr, ketonemia, ↓ PO₄ ↑ osmolality 	<ul style="list-style-type: none"> ↑ BG (44.4-133.2 mmol/L, 800-2400 mg/dL) In mild dehydration, may have hyponatremia (spurious 2° to hyperglycemia → for every ↑ in BG by 10 mmol/L (180 mg/dL) there is a ↓ in Na by 3 mmol/L) – if dehydration progresses, may get hypernatremia Ketosis usually absent or mild if starvation occurs ↑ osmolality
ABG	<ul style="list-style-type: none"> Metabolic acidosis with ↑ AG, possible 2° respiratory alkalosis If severe vomiting/dehydration there may be a metabolic alkalosis 	<ul style="list-style-type: none"> Metabolic acidosis absent unless underlying precipitant leads to acidosis (e.g. lactic acidosis in MI)
Urine	<ul style="list-style-type: none"> +ve for glucose and ketones 	<ul style="list-style-type: none"> -ve for ketones unless there is starvation ketosis Glycosuria
Treatment	<ul style="list-style-type: none"> Immediate resuscitation and emergency measures if patient is stuporous or comatose Monitor degree of ketoacidosis with AG, not BG or serum ketone level Rehydration: <ul style="list-style-type: none"> 1 L/h NS in first 2 hrs after 1st 2 L, 300-400 ml/h 0.45% NS once BG reaches 13.9 mmol/L (250 mg/dL) then switch to D5W to maintain BG in the range of 13.9–16.6 mmol/L (250-300 mg/dL) Insulin therapy: <ul style="list-style-type: none"> critical to resolve acidosis, not hyperglycemia use only regular insulin (R) initially load 0.15 U/kg body weight insulin R bolus maintenance 0.1 U/kg/h insulin R infusion check serum glucose hourly K replacement: <ul style="list-style-type: none"> as acidosis is corrected, hypokalemia may develop when K 3.5-5.5 mmol/L add KCL 30-40mEq/L IV fluid to keep K in the range of 3.5-5 mEq/L HCO₃: <ul style="list-style-type: none"> if pH <7.0 or if hypotension, arrhythmia, or coma is present with a pH of <7.1 give HCO₃ in 0.45% NS do not give if pH >7.1 (risk of metabolic alkalosis!) can give in case of life-threatening hyperkalemia ± mannitol (for cerebral edema) 	<ul style="list-style-type: none"> Same resuscitation and emergency measures as DKA Rehydration: <ul style="list-style-type: none"> IV fluids: 1 L/h NS initially evaluate corrected serum Na if serum Na high or normal, switch to 0.45% NS (4-14 ml/kg/h) if serum Na low, maintain NS (4-14 ml/kg/h) when serum BG reaches 13.9 mmol/L (250 mg/dL) switch to D5W K replacement: <ul style="list-style-type: none"> less severe K depletion compared to DKA if serum K <3.3 mmol/L, hold insulin and give 40 mEq/L K replacement if K is 3.3-5.4, give KCl 20-30 mEq/L IV fluid if serum K ≥5.5 mmol/L, check K every 2 h Search for precipitating event Insulin therapy: <ul style="list-style-type: none"> use only regular insulin (R) initially load 0.15 U/kg body weight insulin R bolus maintenance 0.1 U/kg/h insulin R infusion or IM check serum glucose hourly in general lower insulin requirement compared to DKA
Prognosis	<ul style="list-style-type: none"> 2-5% mortality in developed countries Serious morbidity from sepsis, respiratory complications, thromboembolic complications, and cerebral edema 	<ul style="list-style-type: none"> Overall mortality approaches 50% primarily because of the older patient population and underlying etiology

The 6 I's Precipitating DKA:

Infection
Ischemia or Infarction
Iatrogenic (glucocorticoids)
Intoxication
Insulin missed
Intra-abdominal process
(e.g. pancreatitis, cholecystitis)

All Ketonemia is Not DKA:

Consider starvation or alcohol ketosis.

Average fluid loss runs at 3-6 L in DKA, and 8-10 L in HONK.

**Laboratory Testing: Ketones**

The nitroprusside test for ketones identifies acetone and acetoacetate but does NOT detect beta-hydroxybutyrate (BHB), the ketone most frequently in excess. This has two clinical consequences:

1. Be wary of a patient with a clinical picture of DKA but negative serum or urinary ketones. These could be false negatives.
2. As DKA is treated, BHB is converted to acetone and acetoacetate. Serum or urinary ketones may therefore rise, falsely suggesting that the patient is worsening.

Effect of a Multifactorial Intervention on Mortality in Type 2 DM: The Steno-2 Study
NEJM 2008; 358:580-91

Study: Single centre, randomized, controlled trial.

Patients: Patients (n=160) with Type 2 DM and persistent microalbuminuria.

Intervention: Random assignment to receive either conventional multifactorial treatment or intensified, target-driven therapy involving a combination of medications and focused behaviour modification. Targets included a HbA1C level of <6.5%, a fasting serum total cholesterol level of <4.5 mmol/L, a fasting serum triglyceride level of <1.7 mmol/L, a systolic blood pressure of <130 mmHg, and a diastolic blood pressure of <80 mmHg. Patients were treated with blockers of the renin-angiotensin system because of their microalbuminuria, regardless of blood pressure, and received low-dose aspirin as primary prevention.

Outcomes: The primary end point in the follow-up trial was the time to death from any cause. Other endpoints examined death from cardiovascular causes and various cardiovascular events along with diabetic neuropathy, nephropathy, and retinopathy.

Results: Twenty-four patients in the intensive-therapy group died, as compared with 40 in the conventional-therapy group (hazard ratio, 0.54; 95% confidence interval [CI], 0.32 to 0.89; $P=0.02$). Intensive therapy was associated with a lower risk of death from cardiovascular causes (hazard ratio, 0.43; 95% CI, 0.19 to 0.94; $P=0.04$) and of cardiovascular events (hazard ratio, 0.41; 95% CI, 0.25 to 0.67; $P<0.001$). One patient in the intensive-therapy group had progression to end-stage renal disease, as compared with six patients in the conventional-therapy group ($P=0.04$). Fewer patients in the intensive-therapy group required retinal photocoagulation (relative risk, 0.45; 95% CI, 0.23 to 0.86; $P=0.02$).

Conclusions: In at-risk patients with Type 2 DM, intensive intervention with multiple drug combinations and behaviour modification had sustained beneficial effects with respect to vascular complications and on rates of death from any cause and from cardiovascular causes.

Macrovascular Complications

- increased risk of coronary artery disease (CAD), ischemic stroke, and peripheral vascular disease (PVD) secondary to accelerated atherosclerosis
- coronary artery disease
 - risk of MI is 3-5x higher in those with diabetes compared to age-matched controls
 - CAD is the leading cause of death in Type 2 DM
 - most patients with DM are considered as “high risk” under the risk stratification for CAD (see *Dyslipidemias*, E2)
- ischemic stroke
 - risk of stroke is approximately 2.5x higher in those with diabetes
 - level of glycemia is either a risk factor for stroke or a predictor of a poorer outcome in patients who suffer a stroke
 - HbA1C level is a significant and independent predictor of the risk of stroke
- peripheral vascular disease
 - manifested by intermittent claudication in lower extremities, intestinal angina, foot ulceration
 - risk of foot gangrene is 30x higher in those with diabetes compared to age-matched controls
 - risk of lower extremity amputation is 15x higher in those with diabetes
- treatment
 - tight blood pressure control (<130/80 mmHg)
 - tight glycemic control
 - tight low density lipoprotein (LDL) cholesterol control [LDL <2.0 mmol/L (77 mg/dL)]
 - low-dose ASA in patients with CVD or increased likelihood of CV events
 - ACE inhibitor or angiotensin receptor blocker (ARB) in high-risk patients
 - smoking cessation

Microvascular Complications

DIABETIC RETINOPATHY (see *Ophthalmology*, OP35)

Epidemiology

- Type 1 DM – 25% affected at 5 years, 100% at 20 years
- Type 2 DM – 25% affected at diagnosis, 60% at 20 years
- leading cause of blindness in North America between the ages of 20-74
- most important factor is disease duration

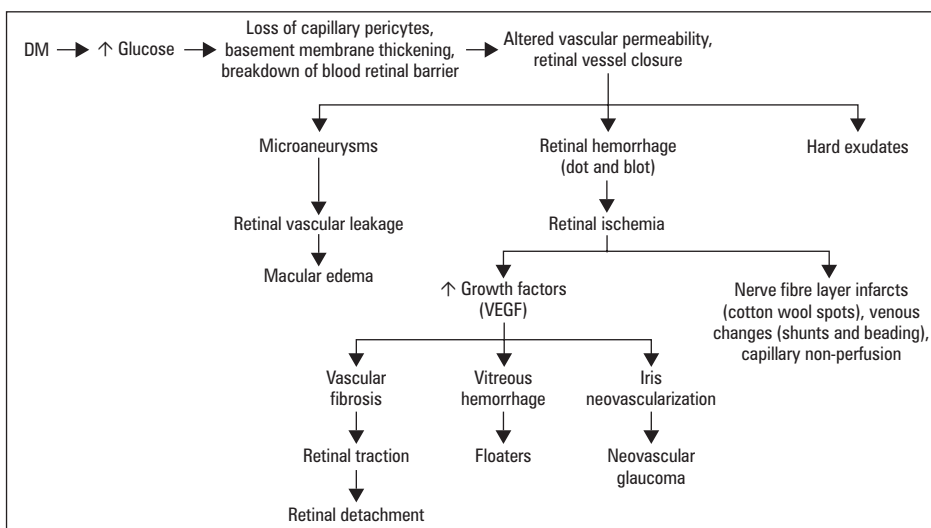

Figure 6. Pathophysiology of Diabetic Retinopathy

Clinical Features

- nonproliferative
 - asymptomatic, but if macular involvement occurs, vision may be impaired
 - microaneurysms, hard exudates, dot and blot hemorrhages
- preproliferative
 - 10-40% progress to proliferative within 1 year
 - macular edema, cotton wool spots, venous shunts and beading, intra-retinal microvascular abnormalities (IRMA)
- proliferative
 - neovascularization, fibrous scarring, vitreous hemorrhage, retinal detachment
 - great risk for loss of vision secondary to vitreous hemorrhage (floaters) and/or retinal detachment

Treatment and Prevention

- tight glycemic control (delays onset, decreases progression)
- if hypertension is present, treat aggressively
- panretinal laser photocoagulation for treatment of neovascularization
- vitrectomy
- annual follow-up visits with an eye specialist (optometrist or ophthalmologist); examination through dilated pupils whether symptomatic or not (immediate referral after diagnosis of Type 2 DM; 5 years after diagnosis of Type 1 DM)
- interval for follow-up should be tailored to severity of retinopathy

DIABETIC NEPHROPATHY (see [Nephrology](#), NP34)**Epidemiology**

- diabetes-induced renal failure is the most common cause of renal failure in North America
- 20-40% of persons with Type 1 DM (after 5-10 years) and 4-20% with Type 2 DM have progressive nephropathy

Pathophysiology

- thickening of capillary basement membrane and glomerular mesangium resulting in glomerulosclerosis and renal insufficiency
- diffuse glomerulosclerosis is more common than nodular intercapillary glomerulosclerosis (Kimmelstiel-Wilson lesions)

Screening

- random urine test for albumin to creatinine ratio (ACR) plus urine dipstick test for all Type 2 DM patients at diagnosis, then annually, and for postpubertal Type 1 DM patients with ≥ 5 years duration of DM

Clinical Features

- initial changes include microalbuminuria, increased GFR (up to 140%), enlarged kidneys
- microalbuminuria: ACR of >2.0 mg/mmol (men) or >2.8 mg/mmol (women)
- macroalbuminuria: ACR of >20.0 mg/mmol (men) or >28.0 mg/mmol (women)
- progression over 15 years to cause hypertension, persistent proteinuria (macroalbuminuria), nephrotic syndrome, and renal failure
- elevated HbA1C is an independent risk factor for progression to microalbuminuria

Treatment and Prevention

- tight glycemic control
- tight blood pressure control ($<130/80$ mmHg) with ACEI or ARB
- numerous studies have shown that even in the absence of glycemic control, ACEIs or ARBs reduce the level of albuminuria and reduce the rate of progression of renal disease in normotensive and hypertensive patients with Type 1 or Type 2 DM
- Type 1 DM \rightarrow if normotensive or hypertensive and patient has microalbuminuria or macroalbuminuria \rightarrow ACE inhibitors 1st line; ARBs 2nd line
- Type 2 DM \rightarrow if normotensive or hypertensive and patient has microalbuminuria or macroalbuminuria \rightarrow ACE inhibitors or ARBs if creatinine clearance (CrCl) >60 ml/min; ARB if CrCl ≤ 60 ml/min
- consider use of non-dihydropyridine calcium channel blocker (e.g. diltiazem) in those unable to tolerate both ACE inhibitors and ARBs
- limit use of nephrotoxic drugs and dyes
- protein restriction (controversial)
- renal failure may necessitate hemodialysis and renal transplant

Management of Diabetic Retinopathy: A**Systematic Review**

JAMA 2007; 298:902-16

Purpose: To review the best evidence for primary and secondary interventions in the management of diabetic retinopathy (DR), including diabetic macular edema.

Study Selection: All English-language randomized controlled trials (RCTs) with more than 12 months of follow-up and meta-analyses were included. Delphi consensus criteria were used to identify well-conducted studies.

Results: Forty-four studies (including 3 meta-analyses) met the inclusion criteria. Tight glycemic and blood pressure control reduces the incidence and progression of DR. Pan-retinal laser photocoagulation reduces the risk of moderate and severe visual loss by 50% in patients with severe nonproliferative and proliferative retinopathy. Focal laser photocoagulation reduces the risk of moderate visual loss by 50 to 70% in eyes with macular edema. Early vitrectomy improves visual recovery in patients with proliferative retinopathy and severe vitreous hemorrhage. Intravitreal injections of steroids may be considered in eyes with persistent loss of vision when conventional treatment has failed. There is insufficient evidence for the efficacy or safety of lipid-lowering therapy, medical interventions, or antivascular endothelial growth factors on the incidence or progression of DR.

Conclusions: Tight glycemic and blood pressure control remains the cornerstone in the primary prevention of DR. Pan-retinal and focal retinal laser photocoagulation reduces the risk of visual loss in patients with severe DR and macular edema, respectively. There is currently insufficient evidence to recommend routine use of other treatments.

Effects of Treatments for Symptoms of Painful Diabetic Neuropathy: Systematic Review
BMJ 2007; 335:87

Purpose: To evaluate the effects of treatments for the symptoms of painful diabetic neuropathy.

Study Selection: Randomised controlled trials comparing topically applied and orally administered drugs with a placebo in adults with painful diabetic neuropathy.

Results: 25 included reports compared anticonvulsants (n=1270), antidepressants (94), opioids (329), ion channel blockers (173), N-methyl-D-aspartate antagonist (14), duloxetine (805), capsaicin (277), and isosorbide dinitrate spray (22) with placebo. The odds ratios in terms of 50% pain relief were 5.33 (95% confidence interval 1.77 to 16.02) for traditional anticonvulsants, 3.25 (2.27 to 4.66) for newer generation anticonvulsants, and 22.24 (5.83 to 84.75) for tricyclic antidepressants. The odds ratios in terms of withdrawals related to adverse events were 1.51 (0.33 to 6.96) for traditional anticonvulsants, 2.98 (1.75 to 5.07) for newer generation anticonvulsants, and 2.32 (0.59 to 9.69) for tricyclic antidepressants. Insufficient dichotomous data were available to calculate the odds ratios for ion channel blockers.

Conclusion: Anticonvulsants and antidepressants are still the most commonly used options to manage diabetic neuropathy. Oral tricyclic antidepressants and traditional anticonvulsants are better for short term pain relief than newer generation anticonvulsants. Evidence of the long term effects of oral antidepressants and anticonvulsants is still lacking. Further studies are needed on opioids, N-methyl-D-aspartate antagonists, and ion channel blockers.

DIABETIC NEUROPATHY (see *Neurology*, N30)

Epidemiology

- approximately 50% of patients within 10 years of onset of Type 1 DM and Type 2 DM

Pathophysiology

- mechanism poorly understood
- acute cranial nerve palsies and diabetic amyotrophy are thought to be due to ischemic infarction of involved peripheral nerve
- the more common motor and sensory neuropathies are thought to be related to metabolic or osmotic toxicity secondary to increased sorbitol and/or decreased myoinositol (possible mechanisms include accumulation of advanced glycation endproducts (AGE), oxidative stress, protein kinase C, nerve growth factor deficiency)
- can have peripheral sensory neuropathy, motor neuropathy, or autonomic neuropathy

Screening

- 128 Hz tuning fork or 10 g monofilament at diagnosis and annually in people with Type 2 DM and after 5 years duration of Type 1 DM

Clinical Features

Table 13. Clinical Presentation of Diabetic Neuropathies

Peripheral Sensory Neuropathy	Motor Neuropathy	Autonomic Neuropathy
Paresthesias (tingling, itching), neuropathic pain, radicular pain, numbness, decreased tactile sensation	Less common than sensory neuropathy	Postural hypotension, tachycardia, decreased cardiovascular response to Valsalva maneuver
Bilateral and symmetric with decreased perception of vibration and pain/temperature; especially true in the lower extremities but may also be present in the hands	Delayed motor nerve conduction and muscle weakness/atrophy	Gastroparesis and alternating diarrhea and constipation
Decreased ankle reflex	May involve one nerve trunk (mononeuropathy) or more (mononeuritis multiplex)	Urinary retention and erectile dysfunction
Symptoms may first occur in entrapment syndromes e.g. carpal tunnel, neuropathic ulceration of foot	Some of the motor neuropathies spontaneously resolve after 6-8 wks	
	Reversible CN palsies: III (ptosis/ophthalmoplegia), VI (inability to laterally deviate eye), and VII (Bell's palsy)	
	Diabetic amyotrophy: refers to pain, weakness, and wasting of hip flexors or extensors	

Treatment and Management

- tight glycemic control
- for neuropathic pain syndromes: tricyclic antidepressants (e.g. amitriptyline), pregabalin, anti-epileptics (e.g. carbamazepine, gabapentin), and capsaicin
- foot care education
- Jobst® fitted stocking and tilting of head of bed may decrease symptoms of orthostatic hypotension
- treat gastroparesis with domperidone and/or metoclopramide (dopamine antagonists), erythromycin (stimulates motilin receptors)
- medical, mechanical and surgical treatment for erectile dysfunction (see *Urology*, U31)

Other Complications

Dermatologic

- diabetic dermopathy: atrophic brown spots commonly in pretibial region known as "shin spots", secondary to increased glycosylation of tissue proteins or vasculopathy
- eruptive xanthomas secondary to increased triglycerides
- necrobiosis lipidica diabetorum: rare complication characterized by thinning skin over the shins allowing visualization of subcutaneous vessels

Bone and Joint Disease

- juvenile cheiroarthropathy: chronic stiffness of hand caused by contracture of skin over joints secondary to glycosylated collagen and other connective tissue proteins
- Dupuytren's contracture
- bone demineralization: bone density 10-20% below normal
- frozen shoulder

Cataracts

- subcapsular and senile cataracts secondary to glycosylated lens protein or increased sorbitol causing osmotic change and fibrosis

Infections

- see *Infectious Diseases*, ID23

Hypoglycemia

Etiology and Pathophysiology

- hypoglycemia occurs most frequently in people with diabetes receiving insulin or certain antihyperglycemic therapies (insulin secretagogues)
- in people without diabetes, care must be taken to distinguish fasting from post-prandial hypoglycemia as each invokes separate differential diagnoses

Table 14. Common Causes of Hypoglycemia

Fasting		Post-Prandial (Nonfasting, Reactive)
Hyperinsulinism	Without Hyperinsulinism	
<ul style="list-style-type: none"> Exogenous insulin Sulfonylurea reaction Autoimmune hypoglycemia (autoantibodies to insulin or insulin receptor) Pentamidine Pancreatic beta cell tumour – insulinoma 	<ul style="list-style-type: none"> Severe hepatic dysfunction Chronic renal insufficiency Hypocortisolism Alcohol use Non-pancreatic tumours Inborn error of carbohydrate metabolism, glycogen storage disease, gluconeogenic enzyme deficiency 	<ul style="list-style-type: none"> Alimentary Functional Noninsulinoma pancreatogenous hypoglycemic syndrome Occult diabetes Leucine sensitivity Hereditary fructose intolerance Galactosemia Newborn infant of diabetic mother

Clinical Features

- Whipple's triad
 - serum glucose <2.5 mmol/L (45 mg/dL) in males and <2.2 mmol/L (40 mg/dL) in females
 - neuroglycopenic symptoms or adrenergic symptoms (autonomic response)
 - relief provided by administration of glucose
- adrenergic symptoms (typically occur first; caused by autonomic nervous system activity)
 - palpitations, sweating, anxiety, tremor, tachycardia
- neuroglycopenic symptoms (caused by decreased activity of CNS)
 - dizziness, headache, clouding of vision, mental dullness, fatigue, confusion, seizures, coma

Investigations

- electrolytes, BUN/creatinine, LFTs, drugs/toxins

Treatment

- for fasting hypoglycemia, must treat underlying cause
- for post-prandial (reactive) hypoglycemia, frequent small feeds
- see Emergency Medicine, ER36
- bloodwork to be drawn when patient is hypoglycemic (i.e. during hospitalized 72-hour fast): serum ketones, insulin, proinsulin, C-peptide, cortisol, and GH
- treatment of hypoglycemic episode in the unconscious patient or patient NPO
 - D50W 50 mL (1 ampule) IV or 1 mg glucagon SC (if no IV available)
 - may need ongoing glucose infusion once BG >5 mmol/L (90 mg/dL)

Metabolic Syndrome

- defined by having three or more risk factors (see sidebar)
- postulated syndrome related to insulin resistance associated with hyperglycemia, hyperinsulinemia, hypertension, central obesity, and dyslipidemia
- obesity aggravates extent of insulin resistance
- complications include atherosclerosis, CAD, MI, and stroke
- not to be confused with syndrome X related to angina pectoris with normal coronary arteries (Prinzmetal angina)

Obesity

- see Family Medicine, FM5

C-Peptide

A short peptide released into the circulation when proinsulin is cleaved to insulin.

Use C-peptide Levels to Distinguish between Exogenous and Endogenous Source of Hyperinsulinemia

Increased = endogenous
Decreased or normal = exogenous

Treatment of Acute Hypoglycemic Episode (Blood Glucose <4.0 mmol/L) in the Awake Patient (e.g. able to self-treat)

- 1) Eat 15 g of carbohydrates (CHO) (e.g. 3 x 5 g glucose tablets; 3 packets sugar dissolved in water; 3/4 cup of juice)
- 2) Wait 15 minutes
- 3) Retest Blood Glucose (BG)
- 4) Repeat steps 1-3 until BG >5 mmol/L
- 5) Eat next scheduled meal. If next meal is >1 hour away, eat snack including 15 g of CHO and protein.

Hypoglycemia Unawareness: (Type 1 DM >>> Type 2 DM)

Patient remains asymptomatic until severely hypoglycemic levels are reached

Causes:

- Decreased glucagon/epinephrine response
- History of repeated hypoglycemia or low HbA1C
- Autonomic dysfunction

Features of Metabolic Syndrome (International Diabetes Federation, 2005)

Risk Factor	Defining level
Abdominal Obesity	
Men	Waist circumference ≥94 cm (37 inches)
Women	Waist circumference ≥80 cm (31.5 inches)
Triglyceride Level	≥1.7 mmol/L (150 mg/dL)
HDL-C Level	
Men	<1.0 mmol/L (<40 mg/dL)
Women	<1.3 mmol/L (<50 mg/dL)
Blood Pressure	≥130/80 mmHg
Fasting Glucose Level	≥5.6 mmol/L (>100 mg/dL)

Pituitary Gland

Pituitary Hormones

The Pituitary Hormones

"Go Look For The Adenoma Please"
GH, LH, FSH, TSH, ACTH, PRL +
posterior pituitary hormones: ADH and
oxytocin

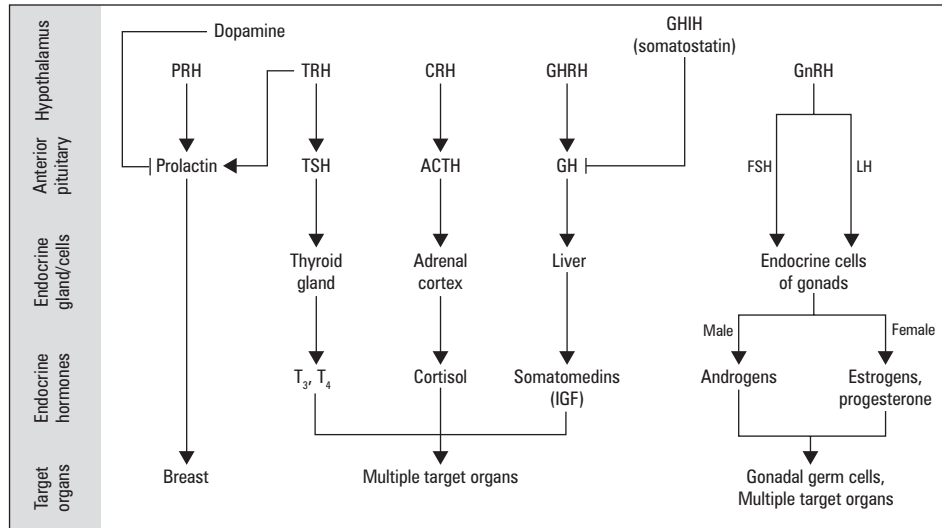

Figure 7. Hypothalamo-Pituitary Hormonal Axes

CRH = corticotrophin-releasing hormone; GnRH = gonadotropin-releasing hormone; GHIH = growth hormone-inhibiting hormone; GHRH = growth hormone-releasing hormone; PRH = prolactin-releasing hormone; TRH = thyrotropin-releasing hormone

Hypothalamic Control of Pituitary

- trophic and inhibitory factors control the release of pituitary hormones
- most hormones are primarily under trophic stimulation except prolactin which is primarily under inhibitory control by dopamine
- transection of the pituitary stalk (i.e. dissociation of hypothalamus and pituitary) leads to pituitary hypersecretion of prolactin and hyposcretion of all remaining hormones

Anterior Pituitary Hormones

- growth hormone (GH), luteinizing hormone (LH), follicle stimulating hormone (FSH), thyroid stimulating hormone (TSH), adrenocorticotrophic hormone (ACTH), and prolactin (PRL)

Posterior Pituitary (Hypothalamic) Hormones

- antidiuretic hormone (ADH) and oxytocin
- peptides synthesized in the supraoptic and paraventricular nuclei of the hypothalamus
- although ADH and oxytocin are produced in the hypothalamus, these hormones are stored and released from the posterior pituitary

Table 15. The Physiology and Action of Pituitary Hormones

Hormone	Function	Physiology	Inhibitory Stimulus	Secretory Stimulus
ACTH	<ul style="list-style-type: none"> • Stimulates growth of adrenal cortex and secretion of its hormones 	<ul style="list-style-type: none"> • Polypeptide • Pulsatile and diurnal variation (peaks at 02:00-04:00; lowest at 18:00-24:00) 	<ul style="list-style-type: none"> • Dexamethasone • Cortisol 	<ul style="list-style-type: none"> • CRH • Metyrapone • Insulin-induced hypoglycemia • Fever, pain, stress
ADH	<ul style="list-style-type: none"> • Acts at renal collecting ducts to cause insertion of aquaporin channels and increases water reabsorption thereby concentrating urine 	<ul style="list-style-type: none"> • Octapeptide • Osmoreceptors in hypothalamus detect serum osmolality • Contracted plasma volume detected by baroreceptors is a more potent stimulus than osmolality 	<ul style="list-style-type: none"> • ↓ serum osmolality 	<ul style="list-style-type: none"> • Hypovolemia or ↓ effective circulatory volume • ↑ serum osmolality • Stress, pain, fever, paraneoplastic • Lung or brain pathology
GH	<ul style="list-style-type: none"> • Needed for linear growth • IGF stimulates growth of bone and cartilage 	<ul style="list-style-type: none"> • Polypeptide • Acts indirectly through serum factors synthesized in the liver: IGF (somatomedins) • Serum GH undetectable for most of the day and suppressed after meals high in glucose • Sustained rise during sleep 	<ul style="list-style-type: none"> • Glucose challenge • Glucocorticoids • Hypothyroidism • Somatostatin • Dopamine agonists • IGF-1 (long-loop) • Tonically by dopamine • D₂ receptor agonists 	<ul style="list-style-type: none"> • Insulin-induced hypoglycemia • Exercise • REM sleep • Arginine, clonidine, propranolol, L-dopa • GHRH

Table 15. The Physiology and Action of Pituitary Hormones (continued)

Hormone	Function	Physiology	Inhibitory Stimulus	Secretory Stimulus
LH/FSH	<ul style="list-style-type: none"> Stimulate gonads via cAMP Ovary: <ul style="list-style-type: none"> LH: production of androgens (thecal cells) which are converted to estrogens (granulosa cells); induces luteinization in follicles FSH: growth of granulosa cells in ovarian follicle; controls estrogen formation Testes: <ul style="list-style-type: none"> LH: production of testosterone (Leydig cells) FSH: production of spermatozoa (Sertoli cells) 	<ul style="list-style-type: none"> Polypeptide Glycoproteins (similar alpha subunit TSH and hCG) Secreted in pulsatile fashion 	<ul style="list-style-type: none"> Estrogen Progesterone Testosterone Inhibin Continuous (i.e. non-pulsatile) GnRH infusion 	<ul style="list-style-type: none"> Pulsatile GnRH
Oxytocin	<ul style="list-style-type: none"> Causes uterine contraction Breast milk secretion 	<ul style="list-style-type: none"> Nonapeptide 	<ul style="list-style-type: none"> EtOH 	<ul style="list-style-type: none"> Suckling Distention of female genital tract via stretch receptors
Prolactin	<ul style="list-style-type: none"> Promotes milk production Inhibits GnRH secretion 	<ul style="list-style-type: none"> Polypeptide Episodic secretion 		<ul style="list-style-type: none"> Sleep Stress, hypoglycemia Pregnancy, breast-feeding Mid-menstrual cycle Sexual activity TRH Drugs: psychotropics, antihypertensives, dopamine antagonists, opiates, high dose estrogen
TSH	<ul style="list-style-type: none"> Stimulates growth of thyroid and secretion of T_3 and T_4 via cAMP 	<ul style="list-style-type: none"> Glycoprotein 	<ul style="list-style-type: none"> Circulating thyroid hormones (T_3, T_4) Opiates, dopamine 	<ul style="list-style-type: none"> TRH Epinephrine Prostaglandins

Growth Hormone (GH)

GH DEFICIENCY

- cause of short stature in children (see [Pediatrics](#), P35)
- controversial significance in adults

GH EXCESS

- gigantism
 - excess GH secretion before epiphyseal fusion
- acromegaly
 - excess GH secretion in adults (after epiphyseal fusion)

Etiology

- GH secreting pituitary adenoma, carcinoid or pancreatic islet tumours secreting ectopic GHRH resulting in excess GH

Pathophysiology

- normally, growth hormone is a catabolic hormone that acts to increase blood glucose levels
- in growth hormone excess states, secretion remains pulsatile, but there is loss of hypoglycemic stimulation, glucose suppression and the nocturnal surge
- proliferation of bone, cartilage, soft tissues, organomegaly
- insulin resistance and IGT

Clinical Features

- enlargement of hands and feet, coarsening of facial features, thickening of calvarium, prognathism, thickening of skin, increased sebum production, sweating, acne, sebaceous cysts, fibromata mollusca, acanthosis nigricans, arthralgia, degenerative osteoarthritis (OA), thyromegaly, renal calculi, hypertension, cardiomyopathy, and DM

Investigations

- glucose suppression test (OGTT) is the most specific test → increased GH in acromegaly
- insulin-like growth factor-1 (IGF-1)

Treatment

- surgery, octreotide (somatostatin analogue), growth hormone receptor antagonist, bromocriptine (dopamine agonist, acts on the pituitary gland to block the production and release of growth hormone), radiation

Signs and Symptoms of Acromegaly:

ABCDEF

Arthralgia/Arthritis
Blood pressure raised
Carpal tunnel syndrome
Diabetes
Enlarged organs
Field defect (visual)

**Approach to Nipple Discharge**

1. Differentiate between galactorrhea (fat droplets present) versus breast discharge (usually unilateral, may be bloody or serous)
2. If galactorrhea, determine if physiologic (e.g. pregnancy, lactation, stress) versus pathologic
3. If abnormal breast discharge, must rule out a breast malignancy

Prolactin (PRL)

HYPERPROLACTINEMIA

Etiology

- prolactinoma: most common pituitary adenoma (prolactin-secreting tumours may be induced by estrogens and grow during pregnancy)
- pituitary stalk lesions
- primary hypothyroidism (increased TRH)
- chronic renal failure resulting in decreased clearance, biliary cirrhosis
- medications with anti-dopaminergic properties are a common cause of high prolactin levels: antipsychotics, antidepressants, antihypertensives, anti-migraine agents (triptans/ergotamines), bowel motility agents (metoclopramide), H₂-blockers (e.g. ranitidine)

Clinical Features

- galactorrhea (secretion of breast milk in men or non-lactating women), infertility, hypogonadism, amenorrhea

Investigations

- serum PRL, TSH, liver enzyme tests, creatinine
- MRI

Treatment

- long-acting dopamine agonist: bromocriptine, cabergoline or quinagolide (Norprolac®)
- surgery ± radiation (rare)
- prolactin-secreting tumours are very slow-growing and sometimes require no treatment
- if medication-induced, consider stopping medication if possible

Luteinizing Hormone (LH) and Follicle Stimulating Hormone (FSH)

HYPOGONADOTROPISM

Clinical Features

- hypogonadism, amenorrhea, erectile dysfunction (ED), loss of body hair, fine skin, testicular atrophy, failure of pubertal development

Treatment

- Pergonal® (combined FSH/LH hormone therapy), hCG, or GnRH analogue if fertility desired
- symptomatic treatment with estrogen/testosterone

HYPERGONADOTROPISM

- 2° hypersecretion in gonadal failure

Antidiuretic Hormone (ADH)

DIABETES INSIPIDUS (DI)

Definition

- disorder resulting from deficient ADH action causing passage of large volumes of dilute urine

Diagnostic Criteria

- fluid deprivation will differentiate true DI (high urine output persists, urine osmolality < plasma osmolality) from psychogenic DI (psychogenic polydipsia)
- response to exogenous ADH will distinguish central from nephrogenic DI

Etiology and Pathophysiology

- central DI: insufficient ADH due to post-pituitary surgery, tumours, stalk lesion, hydrocephalus, histiocytosis, trauma, familial central DI
- nephrogenic DI: collecting tubules in kidneys resistant to ADH (drugs including lithium, hypercalcemia, hypokalemia, chronic renal disease, hereditary nephrogenic DI)
- psychogenic polydipsia must be ruled out

Clinical Features

- passage of large volumes of dilute urine, polydipsia, dehydration

Treatment

- DDAVP/vasopressin for total DI
- DDAVP, chlorpropamide, clofibrate, or carbamazepine for partial DI
- nephrogenic DI treated with solute restriction and thiazide diuretics

**Diagnosing Subtypes of DI with DDAVP Response**

Concentrated urine = Central
No effect = Nephrogenic

SYNDROME OF INAPPROPRIATE ADH SECRETION (SIADH)

Diagnostic Criteria

- hyponatremia with corresponding plasma hypo-osmolality, urine sodium concentration above 40 mEq/L, urine less than maximally diluted (>100 mOsm/kg), euvolemia (edema absent), and absence of adrenal, renal or thyroid insufficiency

Etiology and Pathophysiology

- stress (pain, nausea, post-surgical)
- malignancy (lung, pancreas, lymphoma)
- CNS disease (inflammatory, hemorrhage, tumour, Guillain-Barré syndrome)
- respiratory disease (TB, pneumonia, empyema)
- drugs (vincristine, chlorpropamide, cyclophosphamide, carbamazepine, nicotine, morphine, DDAVP, oxytocin)

Treatment

- treat underlying cause, fluid restriction, vasopressin receptor antagonists (e.g. tolvaptan, conivaptan), and demeclocycline (antibiotic with anti-ADH properties, rarely-used)

SIADH vs. Cerebral Salt Wasting (CSW)
CSW can occur in cases of subarachnoid hemorrhage. Na is excreted by malfunctioning renal tubules, mimicking findings of SIADH.

Pituitary Pathology

PITUITARY ADENOMA (see Neurosurgery, NS13)

Clinical Features

- related to size and location
 - visual field defects (usually bitemporal hemianopsia), oculomotor palsies, increased ICP
 - skull radiograph (rarely done): "double floor" (large sella or erosion), calcification
 - CT and MRI far more sensitive for diagnosis
- related to destruction of gland
 - hypopituitarism
- related to increased hormone secretion
 - PRL (galactorrhea), GH (acromegaly in adults, gigantism in children), ACTH (Cushing's disease = Cushing's syndrome caused by a pituitary tumour)
 - tumours secreting LH, FSH and TSH are rare

EMPTY SELLA SYNDROME

- occurs when subarachnoid space extends into sella turcica, partially filling it with CSF resulting in remodeling and enlargement of sella turcica and flattening of the pituitary gland
- usually eupituitary
- may have headaches
- MRI may show herniation of diaphragm sellae and the presence of CSF in the sella turcica
- no treatment necessary

PITUITARY APOPLEXY

- acute hemorrhage/infarction of pituitary tumour
- sudden severe headache, altered level of consciousness
- ocular symptoms: ophthalmoplegia with pituitary tumour likely indicates apoplexy since tumour rarely gets big enough to encroach on cranial nerves
- neurosurgical emergency: acute decompression of pituitary via trans-sphenoidal route

HYPOPITUITARISM

Etiology

- the eight "I"s
 - Invasive: generally primary tumours
 - Infarction: e.g. Sheehan's syndrome (excessive post-partum blood loss leading to infarction of the pituitary gland)
 - Infiltrative disease: e.g. sarcoidosis, hemochromatosis, histiocytosis
 - Iatrogenic: following surgery or radiation
 - Infectious: e.g. syphilis, TB
 - Injury: severe head trauma
 - Immunologic: autoimmune destruction
 - Idiopathic: familial forms, congenital midline defects

Clinical Features

- typical clinical progression in panhypopituitarism
 - GH (most common deficiency) \rightarrow LH/FSH \rightarrow ACTH \rightarrow TSH
- fall in GH is not clinically apparent
- fall in PRL is variable, but may present as decreased lactation
- gonadotropin insufficiency causes erectile dysfunction in men and amenorrhea or infertility in women
- TSH deficiency produces clinical hypothyroidism
- ACTH deficiency leads to adrenal insufficiency

Important deficiencies to recognize are:
1. Adrenal insufficiency
2. Hypothyroidism

Concurrent adrenal insufficiency and hypothyroidism should be treated with glucocorticoids first and then with thyroid hormone to avoid adrenal crisis.

Regulation of Thyroid Function

- extrathyroid
 - stimulation of thyroid by TSH, epinephrine, prostaglandins (cAMP stimulators)
 - T₃ negatively feeds back on anterior pituitary to inhibit TSH and on hypothalamus to inhibit TRH
- intrathyroid (autoregulation)
 - increasing iodide supply inhibits iodide organification, thus decreasing T₃ and T₄ synthesis (Wolff-Chaikoff effect)
 - there is varying thyroid sensitivity to TSH in response to iodide availability
 - increased ratio of T₃ to T₄ in iodide deficiency
 - increased activity of peripheral 5' deiodinase in hypothyroidism increases T₃ production despite low T₄ levels

Table 16. Summary of Treatments for Hyperthyroidism and Hypothyroidism

Hyperthyroidism	Hypothyroidism
Propylthiouracil	L-thyroxine (dosing different if elderly)
Methimazole	Liothyronine (T ₃)
Beta-blockers	
Ablation with Radioactive Iodine	
Surgical Resection	

Tests of Thyroid Function and Structure

TSH

- sensitive TSH (sTSH) is the best test for assessing thyroid function
- hyperthyroidism
 - primary: TSH is low because of negative feedback from increased levels of circulating T₃ and T₄
 - secondary: increased TSH which results in increased T₃ and T₄
- hypothyroidism
 - primary: increased TSH (most sensitive test) because of less negative feedback from T₃ and T₄
 - secondary: TSH is low with variable response to TRH depending on the site of the lesion (pituitary or hypothalamic)

Free T₃ and Free T₄

- total T₃ and T₄ levels depend on amount of TBG
- TBG increases with pregnancy, oral contraceptive (OCP) use, acute infectious hepatitis, biliary cirrhosis
- TBG decreases with androgens, glucocorticoids, cirrhosis, hyponatremia, phenytoin, ASA, NSAIDs, nephrotic syndrome, severe systemic illness
- free T₃ and T₄ are independent of TBG and measure biological activity
- standard assessment of thyroid function measures TSH and if necessary free T₄ and free T₃

Thyroid Autoantibodies

- thyroglobulin antibodies (TgAb), thyroid peroxidase (microsomal antibodies), TSH receptor inhibiting antibodies
 - increased in Hashimoto's disease; normal variant in 10-20% of individuals
- thyroid stimulating immunoglobulin (TSI)
 - increased in Graves' disease

Plasma Thyroglobulin

- used to monitor residual thyroid activity post-thyroidectomy, e.g. for thyroid cancer recurrence
- undetectable levels may suggest cure, especially on hormone suppression
- normal or elevated levels may suggest persistent, recurrent, or metastatic disease, especially on stimulation

Serum Calcitonin

- not routinely done to investigate thyroid nodules
- ordered if suspicion of medullary thyroid carcinoma or family history of MEN IIa or IIb syndromes

Thyroid Imaging/Scans

- normal gland size 15-20 g (estimated by palpation)
- thyroid U/S
 - to measure size of gland, solid vs. cystic nodule, facilitate FNAB
- thyroid scan (Technetium-99)
 - differentiates between hot (functioning) and cold (non-functioning) nodules
 - to distinguish between three major types of high-uptake hyperthyroidism
 - Graves' disease (diffuse uptake)
 - toxic multinodular goitre (multiple discrete areas)
 - solid toxic adenoma (single intense area of uptake)
 - test of structure – order if there is a thyroid nodule and patient is hyperthyroid

Thyroid Assessment

- Serum thyroid hormones (TSH, T₃, T₄)
- Antibodies
- Thyroglobulin
- Thyroid imaging/scans
- Biopsy (FNA)

Does this Patient have a Goitre?

JAMA 1995; 273:813-17

Clinical diagnosis was based on degree of lateral prominence, visibility, and palpability of the thyroid gland. Most primary studies did not report the specifics of thyroid examination technique, and therefore no evidence exists to support the superiority of any one method.

The combined results of 9 studies detail the accuracy of the clinical examination for the presence of goitre (using ultrasound or autopsy as the gold standard for comparison):

Sensitivity	70% (68%-73%)
Specificity	82% (79%-85%)
LR+	3.8 (3.3 to 4.5)
LR-	0.37 (0.33 to 0.40)

The combined results of 4 studies detail the predictive utility of assessing grades of thyroid gland weight:

Weight	Reference	LR+	95% CI
0-20 g	normal	0.15	(0.10-0.21)
20-40 g	1-2x	1.9	(1.1-3.0)
>40 g	>2x	25.0	(2.6-175)

- radioactive iodine uptake (RAIU)
 - RAIU measures the turnover of iodine by thyroid gland in vivo
 - in areas of low iodine intake and endemic goitre, 24 h RAIU may be as high as 60-90%
 - in areas of high iodine intake, normal 24 h RAIU will be 8-30%
 - RAIU is high in Graves' disease or toxic nodular goitre and low in subacute thyroiditis, active phase of Hashimoto's thyroiditis, and excess iodine intake (e.g. amiodarone, which has high iodine content)
 - test of function – order if patient is hyperthyroid

Thyroid Biopsy

- fine needle aspiration (FNA) for cytology
 - differentiates between benign and malignant disease

Table 17. Summary of Diagnostic Testing in Hyperthyroidism and Hypothyroidism

	Hyperthyroidism	Hypothyroidism
TSH	<ul style="list-style-type: none"> Decreased in primary hyperthyroidism Increased in secondary hyperthyroidism 	<ul style="list-style-type: none"> Increased in primary hypothyroidism Decreased in secondary hypothyroidism
Free T₄	<ul style="list-style-type: none"> Increased in primary hyperthyroidism Increased in secondary hyperthyroidism 	<ul style="list-style-type: none"> Decreased in primary hypothyroidism Decreased in secondary hypothyroidism
RAIU	Graves – increased; homogenous Multinodular Goitre – increased; heterogenous Toxic Nodule – increased in a specific area with suppression elsewhere	No uptake – subacute thyroiditis, antithyroid drugs, recent iodine load
Antibodies	Graves – Thyroid stimulating Ig (TSI)	Hashimoto's – Antithyroid peroxidase (TPO)

Common Etiologies

Table 18. Common Etiologies

Thyrotoxicosis	Hypothyroidism
Graves' Disease	Hashimoto's
Toxic Nodular Goitre	Congenital
Toxic Nodule	Iatrogenic
Thyroiditis	Hypothyroid phase of thyroiditis

Thyrotoxicosis

Definition

- clinical, physiological, and biochemical findings in response to elevated thyroid hormone

Epidemiology

- 1% of general population (4-5% of elderly women)
- F:M = 5:1

Etiology and Pathophysiology

Table 19. Differential Diagnosis of Thyrotoxicosis

Disorder	TSH	Free T ₄ /T ₃	Thyroid Antibodies	RAIU	Other
Hyperthyroidism					
Graves' disease	Decreased	Increased	TSI	Increased	
Toxic Nodular Goitre	Decreased	Increased	—	Increased	
Toxic Nodule	Decreased	Increased	—	Increased	
Thyroiditis	Decreased	Increased	Up to 50% of cases	Decreased	In classical subacute thyroiditis, ESR increased
McCune-Albright syndrome	Decreased	Increased	—	—	At least 2 of polyostotic fibrous dysplasia, café au lait spots, and autonomous endocrine hyperfunction
Jod Basedow	Decreased	Increased	—	Decreased	Iodine induced
Extrathyroidal Sources of Thyroid Hormone					
<ul style="list-style-type: none"> Endogenous (struma ovariae, ovarian teratoma, metastatic follicular carcinoma) 	Decreased	Increased	—	Decreased	
<ul style="list-style-type: none"> Exogenous (drugs) 					

Table 19. Differential Diagnosis of Thyrotoxicosis (continued)

Disorder	TSH	Free T ₄ /T ₃	Thyroid Antibodies	RAIU	Other
Excessive Thyroid Stimulation					
• Pituitary thyrotrophoma	Increased	Increased	—	Increased	
• Pituitary thyroid hormone receptor resistance	Increased	Increased	—	Increased	
• Increased hCG (e.g. pregnancy)	Decreased	Increased	—	Increased	

Clinical Features**Table 20. Clinical Features of Thyrotoxicosis**

General	Fatigue, heat intolerance, irritability, fine tremor
Cardiovascular	Tachycardia, atrial fibrillation, palpitations Elderly patients may have only cardiovascular symptoms, commonly new onset atrial fibrillation
GI	Weight loss with increased appetite, thirst, increased frequency of bowel movements (hyperdefecation)
Neurology	Proximal muscle weakness, hypokalemic periodic paralysis (common in Asians)
GU	Oligomenorrhea, amenorrhea, decreased fertility
Dermatology	Fine hair, skin moist and warm, vitiligo, soft nails with onycholysis (Plummer's nails), clubbing (acropachy), palmar erythema, pretibial myxedema
MSK	Decreased bone mass, proximal muscle weakness
Hematology	Leukopenia, lymphocytosis, splenomegaly, lymphadenopathy (occasionally in Graves' disease)

Treatment

- antithyroid drugs (thionamides: propylthiouracil (PTU) or methimazole (MMI)) for Graves' disease
- beta-blockers for symptom control
- radioactive iodine thyroid ablation
- surgery

Graves' Disease**Definition**

- syndrome characterized by hyperthyroidism with any one of the following features including diffuse goitre, ophthalmopathy, dermopathy (need not appear together)

Epidemiology

- most common cause of thyrotoxicosis
- occurs at any age with peak in 3rd and 4th decade
- F > M = 7:1, 1.5-2% of U.S. women
- familial predisposition: 15% of patients have a close family member with Graves' disease and 50% have family members with positive circulating antibodies
- association with HLA B8 and DR3
- may be associated with other inherited autoimmune disorders (e.g. pernicious anemia, Hashimoto's disease)

Etiology and Pathophysiology

- autoimmune disorder due to a defect in T-suppressor cells
- B lymphocytes produce TSI that binds the TSH receptor and stimulates the thyroid gland
- immune response can be triggered by pregnancy (especially postpartum), iodine excess, lithium therapy, viral or bacterial infections, glucocorticoid withdrawal
- cause of ophthalmopathy uncertain (can occur even when euthyroid) but may include:
 - antibodies against extraocular muscle antigens (fibroblasts implicated) with lymphocytic infiltration
 - glycosaminoglycan deposition
- dermopathy may be related to cutaneous glycosaminoglycan deposition

Clinical Features

- diffuse thyroid goitre ± thyroid bruit secondary to increased blood flow through the gland
- ophthalmopathy: proptosis, lid lag, lid retraction, diplopia, characteristic stare, conjunctival injection
- dermopathy (rare): pretibial myxedema (thickening of dermis that manifests as *non-pitting* edema)
- acropachy: clubbing and thickening of distal phalanges

Investigations

- low TSH
- increased free T₄ (and/or increased T₃)
- positive for TSI

Signs and Symptoms of hyperTHYROIDISM

- Tremor
- Heart rate up
- Yawning (fatigued)
- Restlessness
- Oligomenorrhea/amenorrhea
- Intolerance to heat
- Diarrhea
- Irritability
- Sweating
- Muscle wasting/weight loss

Caution with Thionamides

These drugs are effective in controlling hyperthyroidism and induce permanent remission in 20-30% of patients with Graves' disease. They inhibit thyroid hormone synthesis. They may be used long-term, although they are most often employed to help patients achieve a euthyroid state before definitive treatment.

Severe adverse effects have been rarely reported, and thus use of thionamides is controversial. Adverse effects include teratogenicity, agranulocytosis, hepatotoxicity and ANCA-positive vasculitis.

Radioiodine Therapy for Graves' Disease and the Effect on Ophthalmopathy – A Systematic Review

Clin Endocrinol (Oxf) 2008; Apr 21

Purpose: To assess whether radioiodine therapy (RAI) for Graves' disease GD is associated with increased risk of ophthalmopathy compared with antithyroid drugs (ATDs) or surgery. To assess the efficacy of glucocorticoid prophylaxis in the prevention of occurrence or progression of ophthalmopathy, when used with RAI.

Study Selection: Randomized controlled trials regardless of language or publication status.

Results: RAI was associated with an increased risk of ophthalmopathy compared with ATD (Relative Risk (RR) 4.23, 95% confidence interval (CI): 2.04 to 8.77) but compared with thyroidectomy, there was no statistically significant increased risk (RR 1.59, 95% CI 0.89 to 2.81). The risk of severe GO was also increased with RAI compared with ATD (RR 4.35, 95% CI 1.28 to 14.73). Prednisolone prophylaxis for RAI was highly effective in preventing the progression of GO in patients with pre-existing GO (RR 0.03; 95% CI 0.00 to 0.24). The use of adjunctive ATD with RAI was not associated with any significant benefit on the course of GO.

Conclusions: Radioiodine therapy for Graves' disease is associated with a small but definite increased risk of development or worsening of Graves' ophthalmopathy compared with antithyroid drugs. Steroid prophylaxis is beneficial for patients with pre-existing Graves' ophthalmopathy.

Treatment

- thionamides
 - propylthiouracil (PTU) or methimazole (MMI)
 - inhibit thyroid hormone synthesis by inhibiting peroxidase-catalyzed reactions, thereby inhibiting organification of iodide, blocking the coupling of iodotyrosines, and inhibiting peripheral deiodination of T_4 to T_3
 - most useful in young patients with small glands and mild disease
 - continue treatment until remission occurs (20-40% of patients achieve spontaneous remission at 6-18 months of treatment)
 - small goitre and recent onset are good indicators for long-term remission with medical therapy
 - MMI contraindicated in pregnancy (teratogenic)
 - major side effects: hepatitis and agranulocytosis
 - minor side effects: rash, fever and arthralgias
 - iodinated contrast agents: sodium ipodate and iopanoic acid can inhibit conversion of T_4 to T_3 and are especially effective in combination with MMI
- symptomatic treatment with beta-blockers
- thyroid ablation with radioactive ^{131}I if PTU or MMI trial does not produce disease remission
 - high incidence of hypothyroidism after ^{131}I , requiring lifelong thyroid hormone replacement
 - contraindicated in pregnancy
- subtotal thyroidectomy (indicated rarely for large goitres)
 - risks include hypoparathyroidism and vocal cord palsy
- ophthalmopathy
 - prevent drying
 - high dose prednisone in severe cases
 - orbital radiation, surgical decompression

Prognosis

- course involves remission and exacerbation unless gland is destroyed by radioactive iodine or surgery
- lifetime follow-up needed
- risk of relapse is 37%, 21%, 6% in thionamides, radioiodine ablation, and surgery groups, respectively

Subacute Thyroiditis (Thyrotoxic Phase)

Definition

- acute inflammatory disorder of the thyroid gland characterized by an initial thyrotoxic state followed by hypothyroidism, eventually followed by euthyroidism in most cases
- two subtypes: painful and painless

Etiology and Pathophysiology

- acute inflammation of the thyroid gland characterized by giant cells and lymphocytes
- disruption of thyroid follicles by inflammatory process results in the release of stored hormone rather than excessive production of new thyroid hormone
- painful = viral (usually preceded by URTI), De Quervain's (granulomatous thyroiditis)
- painless = postpartum, auto-immune, lymphocytic
 - occurs in 5-10% of postpartum mothers and is symptomatic in 1/3 of patients

Clinical Features

- thyroid gland enlargement
- two forms
 - painful ("De Quervain's") thyroid, ears, jaw and occiput
 - painless ("Silent")
- fever and malaise may be present, especially in De Quervain's
- postpartum: thyrotoxicosis 2-3 months postpartum with a subsequent hypothyroid phase at 4-8 months postpartum
- may be mistakenly diagnosed as postpartum depression

Laboratory Investigations

- elevated free T_4 , T_3 , low TSH, RAIU markedly reduced
- marked elevation of ESR in painful variety only
- as disease progresses, values consistent with hypothyroidism may appear
- rise in RAIU reflects gland recovery

Treatment

- painful – high dose anti-inflammatories (NSAIDs), prednisone may be required for severe pain, fever, or malaise
- iodinated contrast agents (e.g. iopanoic acid, ipodate) to inhibit peripheral conversion of TH to T_3
- beta-adrenergic blockade is usually effective in reversing most of the hypermetabolic and cardiac symptoms in both subtypes
- if symptomatically hypothyroid may treat short-term with thyroxine

Prognosis

- full recovery in most cases, but permanent hypothyroidism in 10% of painless thyroiditis
- postpartum: most resolve spontaneously without need for supplementation, however may recur with subsequent pregnancies

Toxic Adenoma/Toxic Multinodular Goitre

Etiology and Pathophysiology

- autonomous thyroid hormone production from a functioning adenoma that is hypersecreting T_3 and T_4
- may be singular (toxic adenoma) or multiple (toxic multinodular goitre [Plummer's disease])

Clinical Features

- goitre with adenomatous changes
- tachycardia, heart failure, arrhythmia, weight loss, nervousness, weakness, tremor, and sweats
- atrial fibrillation is a common presentation in the elderly
- seen most frequently in elderly people, often with presentation of atrial fibrillation

Investigations

- low TSH, high T_3 and T_4 (with a larger increase in T_3)
- thyroid scan with increased uptake in nodule(s), and suppression of the remainder of the gland

Treatment

- initiate therapy with PTU or MMI to attain euthyroid state in order to avoid radiation thyroiditis, use high dose radioactive iodine to ablate tissue over weeks
- propranolol often necessary for symptomatic treatment prior to definitive therapy
- surgery may also be used as 1st line treatment

Thyrotoxic Crisis/Thyroid Storm

Definition

- acute exacerbation of all of the symptoms of thyrotoxicosis presenting in a life threatening state secondary to uncontrolled hyperthyroidism – this is a MEDICAL EMERGENCY!

Etiology and Pathophysiology

- often precipitated by infection, trauma, or surgery in a hyperthyroid patient

Differential Diagnosis

- sepsis, pheochromocytoma, malignant hyperthermia, drug overdose

Clinical Features

- hyperthyroidism
- extreme fever (hyperthermia), tachycardia, vomiting, diarrhea, vascular collapse, hepatic failure with jaundice, and confusion
- arrhythmia that may lead to congestive heart failure, pulmonary edema
- mental status changes ranging from delirium to coma

Laboratory Investigations

- increased free T_3 , T_4 , undetectable TSH
- \pm anemia, leukocytosis, hypercalcemia, elevated LFTs

Treatment

- principles are the same as in hyperthyroidism except use higher doses and frequencies
- initiate prompt therapy; do not wait for confirmation from lab
- propranolol (IV) for tachycardia and to decrease peripheral conversion of T_4 to T_3 (watch for CHF)
- supportive: fluid and electrolytes, diuresis, vasopressors, cooling blanket, acetaminophen for pyrexia
- high dose PTU
- iodide (NaI, KI, Lugol's solution) to inhibit release of thyroid hormone
- lithium to inhibit release of thyroid hormone
- dexamethasone to block peripheral conversion, to lower body temperature, and to treat possible underlying autoimmune condition
- if extreme, plasmapheresis or dialysis to remove high circulating thyroid hormone
- treat precipitant

Prognosis

- 50% mortality rate

Hypothyroidism

Thyroid Hormone Replacement for Subclinical Hypothyroidism

Cochrane Database Syst Rev 2007; (3):CD003419

Purpose: To assess the effects of thyroid hormone replacement for subclinical hypothyroidism.

Study Selection: Randomised controlled trials comparing thyroid hormone replacement with placebo or no treatment in adults with subclinical hypothyroidism. Minimum duration of follow-up was one month.

Results: No trial assessed (cardiovascular) mortality or morbidity. Seven studies evaluated symptoms, mood and quality of life with no statistically significant improvement. One study showed a statistically significant improvement in cognitive function. Six studies assessed serum lipids, there was a trend for reduction in some parameters following levothyroxine replacement. Some echocardiographic parameters improved after levothyroxine replacement therapy, like myocardial relaxation, as indicated by a significant prolongation of the isovolumic relaxation time as well as diastolic dysfunction. Only four studies reported adverse events with no statistically significant differences between groups.

Conclusions: In current RCTs, levothyroxine replacement therapy for subclinical hypothyroidism did not result in improved survival or decreased cardiovascular morbidity. Data on health-related quality of life and symptoms did not demonstrate significant differences between intervention groups. Some evidence indicates that levothyroxine replacement improves some parameters of lipid profiles and left ventricular function.

Signs and Symptoms of Hypothyroidism

HIS FIRM CAP

Hypoventilation
Intolerance to cold

Slow HR

Fatigue

Impotence

Renal impairment

Menorrhagia/amenorrhea

Constipation

Anemia

Paresthesia

Definition

- clinical syndrome caused by cellular responses to insufficient thyroid hormone production

Epidemiology

- 2-3% of general population
- F:M = 10:1
- 10-20% of women over age 50 have subclinical hypothyroidism (normal T₄, TSH mildly elevated)
- iodine deficiency most common cause worldwide, but not in North America

Etiology and Pathophysiology

- primary hypothyroidism (90%)
 - inadequate thyroid hormone production secondary to intrinsic thyroid defect
 - iatrogenic: post-ablative (¹³¹I or surgical thyroidectomy)
 - autoimmune: Hashimoto's thyroiditis, chronic thyroiditis, idiopathic, burnt out Graves'
 - hypothyroid phase of subacute thyroiditis
 - drugs: goitrogens (iodine), PTU, MMI, lithium
 - infiltrative disease (progressive systemic sclerosis, amyloid)
 - iodine deficiency
 - congenital (1/4000 births)
 - neoplasia
- secondary hypothyroidism: pituitary hypothyroidism
 - insufficiency of pituitary TSH
- tertiary hypothyroidism: hypothalamic hypothyroidism
 - decreased TRH from hypothalamus (rare)
- peripheral tissue resistance to thyroid hormone (Refetoff syndrome)

Table 21. Interpretation of Serum TSH and Free T₄ in Hypothyroidism

	Serum TSH	Free T ₄
Overt Primary Hypothyroidism	Increased	Decreased
Subclinical Primary Hypothyroidism	Increased	Normal
Secondary Hypothyroidism	Decreased or not appropriately elevated	Decreased

Clinical Features

Table 22. Clinical Features of Hypothyroidism

General	Fatigue, cold intolerance, slowing of mental and physical performance, hoarseness, macroglossia
CVS	Slow pulse, pericardial effusion, bradycardia, hypertension, worsening CHF + angina, hypercholesterolemia, hyperhomocysteinemia, myxedema heart
GI	Weight gain despite poor appetite, constipation
Neurology	Paresthesia, slow speech, muscle cramps, delay in relaxation phase of deep tendon reflexes ("hung reflexes"), Carpal Tunnel syndrome, asymptomatic increase in CK, seizures
GU	Menorrhagia, amenorrhea, impotence
Dermatology	Puffiness of face, periorbital edema, cool and pale, dry and rough skin, hair dry and coarse, eyebrows thinned (lateral 1/3), discolouration (carotenemia)
Hematology	Anemia: 10% pernicious due to presence of anti-parietal cell antibodies
Respiratory	Decreased exercise capacity, hypoventilation secondary to weak muscles, decreased pulmonary responses to hypoxia, sleep apnea due to macroglossia

Treatment

- L-thyroxine (dose range: 0.05-0.2 mg PO OD)
- elderly patients and those with CAD: start at 0.025 mg daily and increase gradually (start low, go slow)
- after initiating L-thyroxine, TSH needs to be evaluated in 6 weeks; doses adjusted until TSH returns to normal reference range
- once maintenance dose achieved, follow-up with patient annually
- secondary/tertiary hypothyroidism:
 - need to rule out and/or treat adrenal insufficiency first
 - monitor via measurement of TSH and also T₄

CONGENITAL HYPOTHYROIDISM

- see [Pediatrics](#), P30

Hashimoto's Thyroiditis

- most common form of primary hypothyroidism in North America
- chronic autoimmune thyroiditis characterized by both cellular and humoral factors in the destruction of thyroid tissue
- two major forms: goitrous and atrophic; both forms share same pathophysiology but differ in the extent of lymphocytic infiltration, fibrosis, and thyroid follicular cell hyperplasia
- goitrous variant usually presents with a rubbery goitre and euthyroidism, then hypothyroidism becomes evident
 - associated with fibrosis
- atrophic variant patients are hypothyroid from the start
 - associated with thyroid lymphoma

Etiology and Pathophysiology

- defect in clone of T-suppressors leads to cell-mediated destruction of thyroid follicles
- B lymphocytes produce antibodies against thyroid components including thyroglobulin, thyroid peroxidase, TSH receptor, Na/I symporter

Risk Factors

- female gender
- genetic susceptibility: increased frequency in patients with Down's syndrome, Turner's syndrome, certain HLA alleles, cytotoxic T-lymphocyte-associated protein 4 (CTLA-4)
- family Hx or personal Hx of other autoimmune diseases
- cigarette smoking
- high iodine intake
- stress and infection

Investigations

- high TSH, low T₃, low T₄
- presence of thyroid peroxidase and thyroglobulin antibodies in serum

Treatment

- if hypothyroid, replace with L-thyroxine (analog of T₄)

Myxedema Coma

Definition

- severe hypothyroidism complicated by trauma, sepsis, cold exposure, MI, inadvertent administration of hypnotics or narcotics, and other stressful events – this is a MEDICAL EMERGENCY!
- rare, but serious mortality when it occurs (up to 60%, despite therapy)

Clinical Features

- hypothermia, hyponatremia, hypoglycemia, hypotension, bradycardia, hypoventilation, generalized edema, unresponsiveness

Investigations

- decreased free T₃ and T₄, increased TSH, decreased glucose
- check ACTH and cortisol for evidence of adrenal insufficiency

Treatment

- aggressive treatment required
- ABCs – patient should be in ICU setting
- corticosteroids (due to the possibility of concomitant adrenal insufficiency): hydrocortisone 100 mg q8h
- L-thyroxine 0.2-0.5 mg IV loading dose, then 0.1 mg IV OD until oral therapy tolerated
- supportive measures: mechanical ventilation, fluids, vasopressor drugs, passive rewarming, IV dextrose
- monitor for arrhythmia

Sick Euthyroid Syndrome (SES)

Definition

- changes in circulating thyroid hormones amongst patients with serious illness, trauma, or stress
- not due to intrinsic thyroid or pituitary disease

Pathophysiology

- the abnormalities in SES include alterations in
 - peripheral transport and metabolism of thyroid hormone
 - regulation of TSH secretion
 - thyroid function itself

Labs

- initially decreased free T_3 followed by decreased TSH and finally decreased free T_4

Etiology**Table 23. Etiology of SES**

Types of SES	Features
Normal-T_4 variant	<ul style="list-style-type: none"> Low free T_3, normal free T_4, normal TSH Proposed mechanism: inhibition of peripheral 5' monodeiodination of T_4 to T_3
Low-T_4 variant	<ul style="list-style-type: none"> Low free T_3, low free T_4, normal or low TSH Low T_4 likely due to inhibited T_4 binding to serum proteins and accelerated metabolic clearance Poorer prognosis

Treatment

- treat the underlying disease; thyroid hormone replacement worsens outcomes

Non-Toxic Goitre

Definition

- generalized enlargement of the thyroid gland in a euthyroid individual that does not result from inflammatory or neoplastic processes

Pathophysiology

- the appearance of a goitre is more likely during adolescence, pregnancy, and lactation because of increased thyroid hormone requirements
 - early stages: goitre is usually diffuse
 - later stages: multinodular non-toxic goitre with nodule, cyst formation and areas of ischemia, hemorrhage, and fibrosis

Etiology

- iodine deficiency or excess
- goitrogens: brassica vegetables (turnip, cassava)
- drugs: iodine, lithium, para-aminosalicylic acid
- any disorder of hormone synthesis with compensatory growth
- peripheral resistance to thyroid hormone

Treatment

- remove goitrogens
- suppression with L-thyroxine (rarely done)
- surgery may be necessary for severe compressive symptoms

Complications

- compression of neck structures causing stridor, dysphagia, pain, and hoarseness
- multinodular goitre may become autonomous leading to toxic multinodular goitre and hyperthyroidism

Thyroid Nodules

Definition

- clearly defined discrete mass, separated from the thyroid parenchyma
- palpable nodules are found in approximately 4% of the population
- M:F = 1:4

Etiology

- benign tumours (e.g. follicular adenoma)
- thyroid malignancy
- hyperplastic area in a multinodular goitre
- cyst: true thyroid cyst, area of cystic degeneration in a multinodular goitre

Investigations

- thyroid ultrasound to determine size and characteristic (cystic versus solid)
- thyroid function tests
- thyroid scan only if TSH is low to determine if nodule is hot (i.e. significant ^{131}I uptake into nodule) which signifies very low malignant potential
- FNA for all nodules >1-1.5 cm

Thyroid Malignancies

- see Otolaryngology, OT37

Adrenal Cortex

Adrenocorticotropin Hormone (ACTH)

- a polypeptide secreted in a pulsatile fashion from the anterior pituitary with diurnal variability (peak: 0200-0400; trough: 1800-2400)
- part of a prohormone (pro-opiomelanocorticotropin, POMC) which contains alpha, beta and gamma melanocyte-stimulating hormones, beta-endorphin and beta-lipotropin as well as ACTH
- secretion of ACTH regulated by corticotropin-releasing hormone (CRH) and arginine vasopressin
- stimulates growth of adrenal cortex and secretion of its hormones via cAMP
- stimulates release of glucocorticoids, androgens and, to a limited extent, mineralocorticoids
- some melanocyte stimulating activity

Adrenocortical Hormones

- all derived from cholesterol
 - mineralocorticoids (aldosterone) from zona glomerulosa
 - glucocorticoids (cortisol) from zona fasciculata
 - androgens (DHEA, androstenedione) from zona reticularis

Aldosterone

- a mineralocorticoid, which regulates extracellular fluid (ECF) volume through Na (and Cl^-) retention and K (and H^+) excretion (by stimulation of distal tubule Na/K ATPase)
- regulated by the renin-angiotensin-aldosterone system
- negative feedback to juxtaglomerular apparatus (JGA) by long loop (aldosterone via volume expansion) and short loop (angiotensin II via peripheral vasoconstriction)

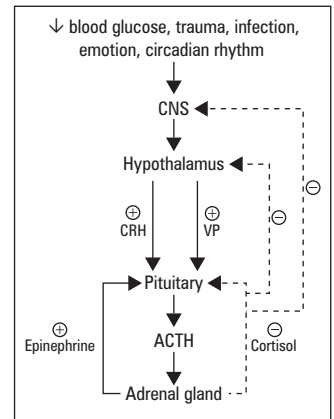

Figure 9. Regulation of CRH-ACTH-Adrenal Gland Axis

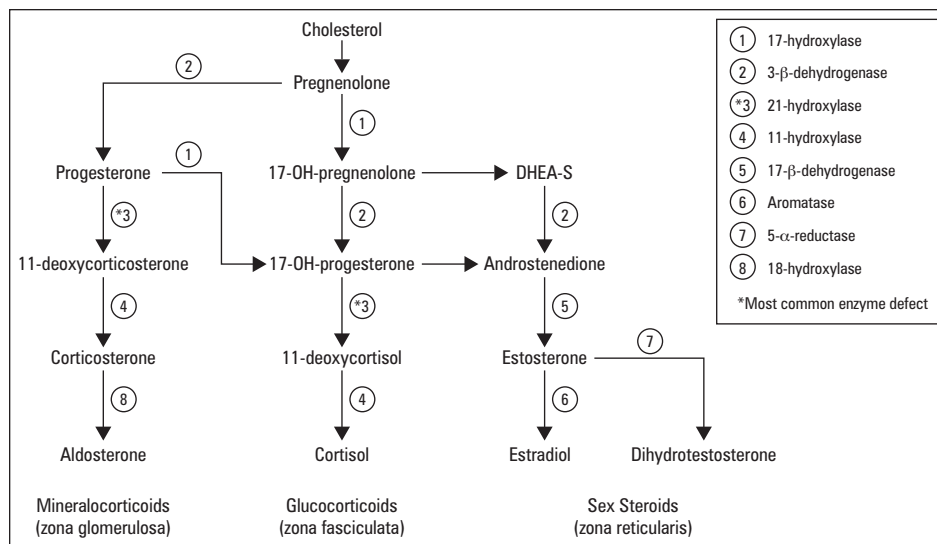

Figure 10. Pathways of Major Steroid Synthesis in the Adrenal Gland and their Enzymes

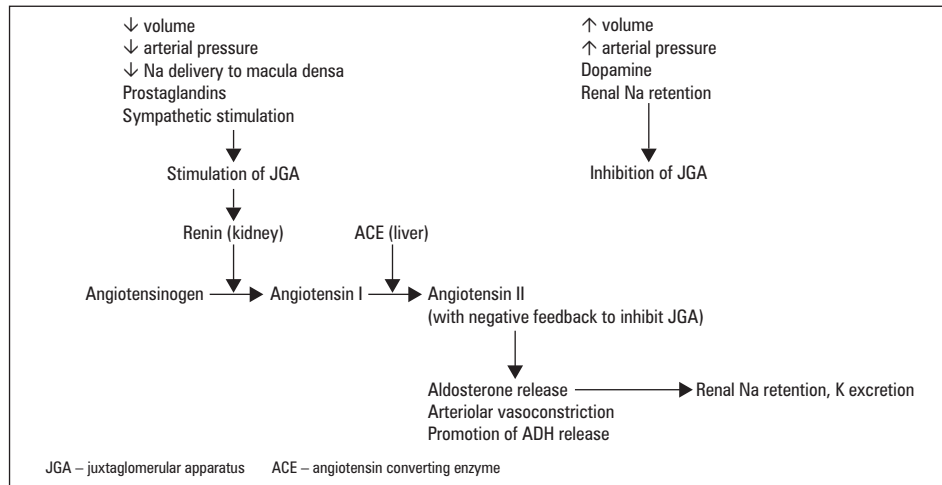

Figure 11. Renin-Angiotensin-Aldosterone Axis, (see [Nephrology](#))

Cortisol

Table 24. Physiological Effects of Glucocorticoids

Stimulatory Effects	Inhibitory Effects
Stimulate hepatic glucose production (gluconeogenesis)	Inhibit bone formation; stimulate bone resorption
Increase insulin resistance in peripheral tissues	Inhibit fibroblasts, causing collagen and connective tissue loss
Increase protein catabolism	Suppress inflammation; impair cell-mediated immunity
Stimulate leukocytosis and lymphopenia	Inhibit growth hormone axis
Increase cardiac output, vascular tone + Na retention	Inhibit reproductive axis
Increase PTH release, urine calcium excretion	Inhibit vitamin D ₃ and inhibit calcium uptake

Androgens

- sex steroids regulated by ACTH; primarily responsible for adrenarche (growth of axillary and pubic hair)
- principal adrenal androgens are dihydroepiandrosterone (DHEA), androstenedione and 11-hydroxyandrostenedione
- proportion of total androgens (adrenal to gonadal) increases in old age

Tests of Adrenocortical Function

Table 25. Markers of Adrenocortical Function

Plasma cortisol	Diurnal variation (random level less useful) Response to stimulation or suppression more informative
24 hour urinary free cortisol	Correlates well with secretory rates Good screening test for adrenal hyperfunction
Serum morning ACTH	High in primary adrenal insufficiency Low in secondary adrenal insufficiency
Serum DHEA-S	The main adrenal androgen

Dexamethasone (DXM) Suppression Tests (DST)

- gold standard to determine presence and etiology of hypercortisolism
- principle: DXM suppresses pituitary ACTH, so plasma cortisol should be lowered by negative feedback if HPA axis were normal
- single dose DST: screening test
 - DXM 1 mg given at 2300h would suppress pituitary ACTH production in healthy individuals, so that the normal 0800h peak of plasma cortisol would fail to develop
 - 95% of Cushing's syndrome patients would fail to suppress
 - <20% false positive results due to obesity, depression, alcohol, other medications
- confirmatory tests
 - low dose DST: 0.5 mg DXM q6h for 48 hours, then 24 hour urinary free cortisol (UFC)
 - ♦ normally, UFC level would be reduced to <54 nmol/day (149 µg/d)
 - high dose DST (8 mg/day): 70-80%
 - ♦ suppressed UFC: adrenal cortex hyperplasia due to hypersecretion of pituitary ACTH
 - ♦ no change in UFC or serum cortisol: adrenal cortisol-producing adenoma/carcinoma
 - however, 30-40% of ectopic ACTH tumours may partially suppress UFC
- plasma ACTH assay supplements DST for differentiation of the various etiologies of Cushing's

Short Cosyntropin Stimulation Test (ACTH analogue)

- for diagnosing adrenal insufficiency; dexamethasone does not interfere with this assay
- give 250 µg cosyntropin IM or IV then measure serum cortisol and ACTH at baseline, and cortisol at 0, 30 and 60 minutes
- physiological response: increase in plasma cortisol level by >250-500 µmol/L or doubling of baseline and an absolute level of >550 µmol/L (rules out primary adrenal insufficiency)
- inappropriate response: inability to stimulate increased plasma cortisol

Hyperaldosteronism

Table 26. Hyperaldosteronism

	Primary Hyperaldosteronism (PH)	Secondary Hyperaldosteronism (SH)
Definition	• Diastolic hypertension without edema	High aldosterone in response to activation of RAAS
Etiology	<ul style="list-style-type: none"> • Aldosterone-producing adrenal adenoma (Conn's syndrome) (75%) • Bilateral adrenal hyperplasia (25%) <ul style="list-style-type: none"> – Idiopathic – Glucocorticoid-remediable aldosteronism • Adrenal carcinoma (1%) • Adrenal enzyme defect/deficiency <ul style="list-style-type: none"> – 11β-HSD type II – 11β-hydroxylase – 17α-hydroxylase 	<ul style="list-style-type: none"> • Renin-producing tumour (rare) • Renal artery stenosis (renovascular hypertension) • CHF, cirrhosis, nephrotic syndrome • Diuretic/laxative abuse • Bartter's syndrome
Common Clinical Features	<ul style="list-style-type: none"> • Hypertension refractory to standard treatment • Polyuria, polydipsia, nocturia • Fatigue, weakness, paresthesia, headache; severe cases with tetany, intermittent paralysis • Labs: low K, high Na, low Mg, alkalosis, salt craving (also measure 24 hr metanephrines and catecholamines to r/o pheo) • Normal K, low Na in SH (low effective circulating volume leads to ↑ ADH release) 	
Diagnosis	<ul style="list-style-type: none"> • ↓ renin, ↑ aldosterone (>15 ng/dl) • Plasma aldosterone:renin ratio >20 ng/dL (normal ≤10 ng/dL) • Confirmatory tests: eaptopril suppression test, 24 h urine aldosterone, salt loading test • If suspecting adenoma: postural stimulation test, furosemide stimulation test, CT adrenal 	<ul style="list-style-type: none"> • ↑ renin, ↑ aldosterone • Aldosterone: renin ≤10 ng/dL
Treatment	<ul style="list-style-type: none"> • Medical tx for adrenal hyperplasia <ul style="list-style-type: none"> – Spironolactone, amiloride • Surgical removal for adrenal adenoma 	• Treat underlying cause

Cushing's Syndrome

**Definition**

- results from chronic glucocorticoid excess (endogenous or exogenous sources)

Etiology

- ACTH-dependent (85%) – bilateral adrenal hyperplasia and hypersecretion due to:
 - ACTH-secreting pituitary adenoma (Cushing's disease; 80% of ACTH-dependent)
 - ectopic ACTH-secreting tumour (e.g. small cell lung carcinoma, bronchial, carcinoid, pancreatic islet cell, pheochromocytoma or medullary thyroid tumours)
- ACTH-independent (15%)
 - long-term use of exogenous glucocorticoids (10 mg/d for >3 weeks)
 - primary adrenocortical tumours: adenoma and carcinoma (uncommon)
 - bilateral adrenal nodular hyperplasia
 - major depression and alcoholism

Clinical Features

Figure 12. Clinical Features of Cushing's Syndrome

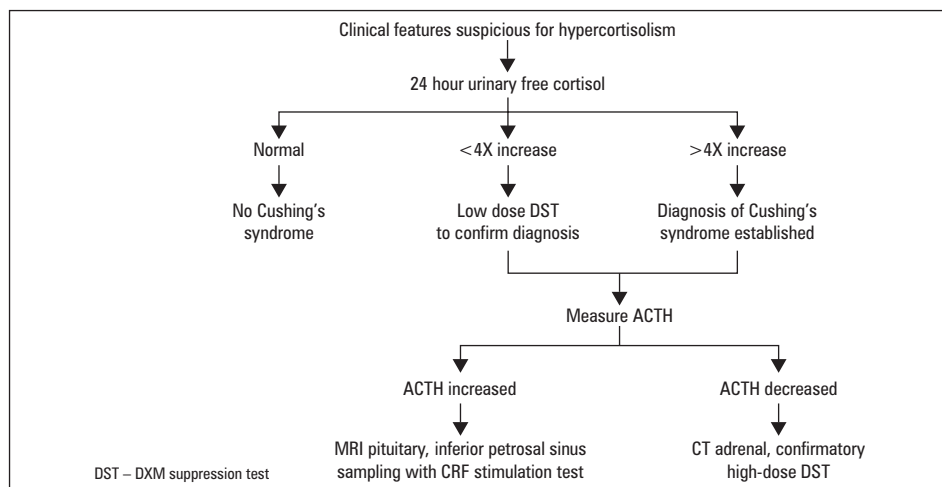

Figure 13. Hypercortisolism: Algorithm for Diagnosis

Treatment

- pituitary
 - trans-sphenoidal resection, with glucocorticoid supplement peri- and post-operatively
 - irradiation: only 50% effective, with significant risk of hypopituitarism
- adrenal
 - adenoma: unilateral adrenalectomy (curative)
 - carcinoma: palliative (frequent metastases, poor prognosis); adjunctive chemotherapy often not useful
 - medical treatment: mitotane, ketoconazole to reduce cortisol
- ectopic ACTH tumour – usually bronchogenic cancer (paraneoplastic syndrome)
 - chemotherapy/radiation for primary tumour
 - agents blocking adrenal steroid synthesis: metyrapone or ketoconazole
 - poor prognosis

Congenital Adrenal Hyperplasia

- see [Pediatrics](#), P32

Hyperandrogenism

Definition

- state of having excessive secretion of adrenal androgens (DHEA, DHEA sulfate)

Etiology and Pathophysiology

Table 27. Etiology of Hyperandrogenism

Constitutional/Familial	Family history, predisposing ethnic background Premature adrenarche
Medications	Anabolic steroids, ACTH, androgens, progestational agents
Androgen-mediated	
Ovarian	PCOS (see Gynecology , GY23) Ovarian hyperthecosis Theca cell tumours Pregnancy: placental sulfatase/aromatase deficiency
Adrenal	Congenital adrenal hyperplasia (CAH, late-onset CAH) Tumours (adenoma, carcinoma)
Pituitary	Cushing's disease – high ACTH Hyperprolactinemia

Clinical Features

Hirsutism

- male pattern growth of androgen-dependent terminal body hair in women: back, chest, upper abdomen, face, linea alba

Virilization

- masculinization: hirsutism, temporal balding, clitoral enlargement, deepening of voice, acne
- increase in musculature

Defeminization

- loss of female secondary sex characteristics (i.e. amenorrhea, ↓ breast size, infertility)

Males

- minimal effects on hair, muscle mass, etc.
- inhibition of gonadotropin secretion may cause reduction in testicular size, testicular testosterone production and spermatogenesis

Investigations

- increased testosterone
- increased LH/FSH, commonly in PCOS >2.5
- DHEA-S as measure of adrenal androgen production
- 17-OH progesterone is elevated in CAH due to 21-OH deficiency
- CT/MRI of adrenals (identify tumours)

Treatment

- discontinue causative medications
- oral contraceptives (e.g. cyproterone acetate – blocks androgen receptor; found in Diane 35®)
- spironolactone – acts as peripheral androgen antagonist
- cosmetic therapy
- low dose glucocorticoid ± mineralocorticoid if CAH suspected
- surgical resection of adrenal tumour

Two Conditions that do NOT Represent True Hirsutism

1. Androgen-independent hair (e.g. lanugo hair)
2. Drug-induced hypertrichosis (e.g. phenytoin, diazoxide, cyclosporine, minoxidil)

Adrenocortical Insufficiency

PRIMARY (ADDISON'S DISEASE)

Etiology

Table 28. Etiology of Primary Adrenocortical Insufficiency

Autoimmune (70-90%)	Isolated adrenal insufficiency Polyglandular autoimmune syndrome type I & II
Infection	TB (7-20%) (most common in developing world) Fungal: histoplasmosis, paracoccidioidomycosis HIV, CMV Syphilis African trypanosomiasis
Infiltrative	Metastatic cancer (lung>stomach>esophagus>colon>breast); lymphoma Sarcoidosis, amyloidosis, hemochromatosis
Vascular	Bilateral adrenal hemorrhage Sepsis (meningococcal, <i>Pseudomonas</i>) Coagulopathy in adults or Waterhouse-Friderichsen syndrome in children Thrombosis, embolism, adrenal infarction
Drugs	Inhibit cortisol: ketoconazole, megestrol acetate Increase cortisol metabolism: rifampin, phenytoin, barbituates, heparin, coumadin
Others	Adrenoleukodystrophy Congenital adrenal hypoplasia (impaired steroidogenesis) Familial glucocorticoid deficiency or resistance

- autoimmune etiology most common in developed world
 - antibodies often directed against adrenal enzymes and 3 zones of cortex

SECONDARY ADRENOCORTICAL INSUFFICIENCY

- inadequate pituitary ACTH secretion
- multiple etiologies (see *Hypopituitarism*, E19), including withdrawal of exogenous steroids that suppress pituitary ACTH production

Clinical Features

Table 29. Clinical Features of Primary and Secondary Adrenal Insufficiency (AI)

	Primary AI (Addison's or Acute AI)	Secondary AI
Skin and mucosa	Dark (palmar crease, extensor surface)	Pale
Potassium	High	Normal
Sodium	Low	Normal or Low
Metabolic acidosis	Present	Absent
Associated diseases	Primary hypothyroidism, type 1 diabetes, vitiligo, neurological deficits	Central hypogonadism or hypothyroidism, growth hormone deficiency, diabetes insipidus, headaches, visual abnormalities
Associated symptoms	Weakness, fatigue, weight loss, hypotension, salt craving, postural dizziness, myalgia, arthralgia, GI: nausea, vomiting, abdominal pain, diarrhea	NO hyperpigmentation NO salt craving GI less common
Diagnostic test	High morning plasma ACTH High 2 hour upright plasma renin	Low morning plasma ACTH Low 2 hour upright plasma renin

Adapted from: Salvatori, R. *JAMA* 2005;294:2481-2488.

Treatment

- acute condition – can be life-threatening
 - IV NS or D5W/NS in large volumes (2-3 L)
 - hydrocortisone 100 mg IV q6-8h for 24h, then gradual tapering
 - identify and correct precipitating factors
- maintenance
 - hydrocortisone 15-20 mg PO qam and 5-10 mg qpm (4:00 pm)
 - Florinef® (fludrocortisone, synthetic mineralocorticoid) 0.05-0.2 mg PO daily if mineralocorticoid deficient (maintain renin between 1-3 ng/ml/hr)
 - increase dose of steroids 2-3 fold for a few days during moderate-severe illness (vomiting, fever)
 - major stress (surgery, trauma) requires 150-300 hydrocortisone IV daily divided into 3 doses
 - medical alert bracelet and instructions for emergency hydrocortisone IM injection

Adrenal Medulla

Catecholamine Metabolism

- catecholamines are synthesized from tyrosine in postganglionic sympathetic nerves and chromaffin cells of adrenal medulla
- predominant adrenal catecholamine = epinephrine (adrenaline)
- predominant peripheral catecholamine = norepinephrine (noradrenaline)

ABC of Adrenaline
Adrenaline activates
Beta-receptors, increasing
Cyclic AMP

Pheochromocytoma

Definition

- rare catecholamine secreting tumour derived from chromaffin cells of the sympathetic system

Epidemiology

- most commonly a single tumour of adrenal medulla
- 10% extra-adrenal (95% of which are intra-abdominal), 10% multiple tumours, 10% malignant, 10% familial
- rare cause of hypertension (<0.2% of all hypertensives)
- curable if recognized and properly treated, but fatal if not

Etiology and Pathophysiology

- most cases sporadic (80%)
- familial: associated with multiple endocrine neoplasia II (MEN II) (50%), von Hippel-Lindau (10-20%), paraganglioma (20%), or neurofibromatosis type 1 (NF I) (0.1-5.7%)
- tumours, via unknown mechanism, able to synthesize and release excessive catecholamines

Clinical Features

- 50% suffer from paroxysmal HTN; the rest have sustained HTN
- classic triad: episodic "pounding" headache, palpitations/tachycardia, diaphoresis
- other symptoms: tremor, anxiety, chest or abdominal pain, nausea/vomiting, visual blurring, weight loss, polyuria, polydipsia
- other signs: orthostatic hypotension, papilledema, increased ESR, hyperglycemia, dilated cardiomyopathy
- symptoms may be triggered by stress, exertion, anesthesia, abdominal pressure, certain foods (especially tyramine containing foods)

Classic Triad of PHEOchromocytoma
Palpitations
Headache
Episodic sweating

Investigations

- urine catecholamines
 - increased catecholamine metabolites (metanephrines) and free catecholamines
 - total metanephrine (most sensitive) >6.5 $\mu\text{mol/day}$ (1.2 mg/day)
- plasma catecholamines
 - >2000 pg/ml (11.8 mmol/L) diagnostic
 - >950 pg/ml (5.6 mmol/L) suggestive; proceed to clonidine suppression test (rarely done)
 - elevated plasma epinephrine unsuppressed by clonidine (central alpha-adrenergic) is diagnostic
- CT abdomen
 - if CT is negative, meta-iodo-benzoguanidine (MIBG) scintigraphy, Octreoscan, or MRI may be helpful

Treatment

- adequate pre-operative preparation
- alpha-blockade for BP control – phenoxybenzamine (14-21 days pre-operative), IV phentolamine (peri-operative)
- beta-blockade for HR control – propranolol (initiate only after adequate alpha-blockade)
- metyrosine (catecholamine synthesis inhibitor) + phenoxybenzamine or prazosin
- volume restoration with vigorous salt-loading
- surgical removal of tumour with careful pre-operative and post-operative ICU monitoring
- rescreen urine one month post-operatively

Multiple Endocrine Neoplasm (MEN)

- neoplastic syndromes involving multiple endocrine glands
- tumours of neuroectodermal origin
- autosomal dominant inheritance with variable penetrance
- genetic screening for RET proto-oncogene on chromosome 10 has long-term benefit
 - early cure and prevention of medullary thyroid cancer

Table 30. MEN Classification

Type	Chromosome Implicated	Tissues Involved	Clinical Manifestations
MEN I Wermer's Syndrome	11 (PYGM gene)	Pituitary Parathyroid Entero-pancreatic endocrine	Ant. pituitary adenoma, often non-secreting but may secrete GH and PRL Primary hyperparathyroidism from hyperplasia Pancreatic islet cell tumours Gastrinoma (peptic ulcers) Insulinomas (hypoglycemia) VIPomas (secretory diarrhea)
MEN II 3 Distinct Syndromes	10 (RET proto-oncogene)		
1. Ila Sipple's Syndrome		Thyroid Adrenal medulla Parathyroid Skin	Medullary thyroid cancer (MTC) (>90%) Pheochromocytoma (40-50%) 1° parathyroid hyperplasia (10-20%) Cutaneous lichen amyloidosis
2. Familial Medullary Thyroid Ca. (a variant of Ila)		Thyroid	MTC without other clinical manifestations of MEN Ila or IIb
3. IIb		Thyroid Adrenal medulla Neurons MSK GI	MTC: most common component, more aggressive and earlier onset than MEN Ila Pheochromocytoma Mucosal neuroma, intestinal ganglioneuromas Marfanoid habitus (no aortic abnormalities) Chronic constipation Megacolon

History

- MEN I
 - symptoms of hyperparathyroidism, gastrinoma (abdominal pain, diarrhea, peptic ulcer disease), and insulinoma
- MEN II
 - family history of MEN syndromes
 - symptoms related to medullary thyroid cancer (MTC), hyperparathyroidism, or pheochromocytoma
 - scaly skin rash (cutaneous lichen amyloidosis in MEN Ila)

Clinical Features

- clinical picture depends on the endocrine organs involved and the hormones secreted
- MEN I
 - hyperparathyroidism – nephrolithiasis, bone abnormalities, MSK complaints
 - generalized weakness, and alterations of mental status in severe hypercalcemia
 - gastrinoma – upper abdominal pain due to peptic ulcers and esophagitis
 - glucagonoma – rash, anorexia, anemia, diarrhea, glossitis
 - pituitary tumour – headache, visual-field defects, prolactinoma (erectile dysfunction, decreased libido, amenorrhea, galactorrhea), acromegaly
 - carcinoid syndrome – flushing, diarrhea, bronchospasm
- MEN II – physical signs are variable and often subtle
 - MTC – neck mass or thyroid nodule; non-tender, anterior neck lymph nodes
 - pheochromocytoma – elevated BP and HR

MEN I – Wermer's Syndrome Affects the 3 Ps

Pituitary
Parathyroid
Pancreas

Investigations

- MEN I
 - laboratory
 - ♦ gastrinoma – elevated serum gastrin level (>200 ng/mL) after IV injection of secretin
 - ♦ insulinoma – reduced fasting blood glucose (hypoglycemia)
 - ♦ glucagonoma – elevated blood glucose and glucagon levels
 - ♦ pituitary tumours – assess GH and prolactin levels
 - ♦ hyperparathyroidism – PTH levels; bone density scan (DEXA)
 - imaging
 - ♦ MRI for pituitary tumours, gastrinoma, insulinoma
- MEN II
 - laboratory
 - ♦ genetic screening for RET mutations in all index patients
 - if a mutation is identified, screen family members who are at risk
 - ♦ calcitonin levels, urine catecholamines, vanillylmandelic acid and metanephrine screen (pheochromocytoma); serum Ca and PTH levels (hyperparathyroidism)
 - ♦ pentagastrin \pm calcium stimulation test if calcitonin level is within reference range
 - imaging
 - ♦ CT or MRI for imaging of the adrenal glands
 - ♦ metaiodobenzylguanidine (MIBG) scan for pheochromocytoma
 - ♦ radionuclide scanning for determining the extent of metastasis
 - ♦ octreoscan for examining the spread of MTC
 - ♦ FNA for thyroid nodules

Treatment

- MEN I
 - surgery is indicated for hyperparathyroidism, insulinoma, glucagonoma, pituitary tumours (trans-sphenoidal approach with external radiation when medical treatment fails)
 - ♦ proton pump inhibitor (PPI) for acid hypersecretion in gastrinoma
 - ♦ bromocriptine or other dopamine agonists to suppress prolactin secretion
 - ♦ somatostatin for symptomatic carcinoid tumours
- MEN II
 - surgery for MEN IIa
 - pre-operative treatment
 - ♦ prostaglandin inhibitors to alleviate diarrhea associated with thyroid cancer
 - ♦ alpha-blocker for at least 2 weeks for pheochromocytoma
 - ♦ hydration for hypercalcemia
 - if remains severely hypercalcemic, consider calcitonin or bisphosphonates
 - post-operative treatment
 - ♦ hormone replacement following total thyroidectomy and bilateral adrenalectomy
 - ♦ calcium supplement and/or vitamin D for post-op hypoparathyroidism

Calcium Homeostasis

- normal total serum Ca: 2.25-2.62 mmol/L (9.0-10.5 mg/dL)
- ionic/free Ca levels: 1.15-1.31 mmol/L (4.6-5.25 mg/dL)
- serum Ca is about 50% protein bound (mostly albumin)
- regulated mainly by two factors: parathyroid hormone (PTH) and vitamin D
- actions mainly on 3 organs: GI tract, bone, and kidney

Parathyroid Hormone (PTH)

- secretion increased by low serum Ca and inhibited by chronic, low serum Mg
- not influenced directly by PO_4 (except by PO_4 effect on the ionic calcium levels)

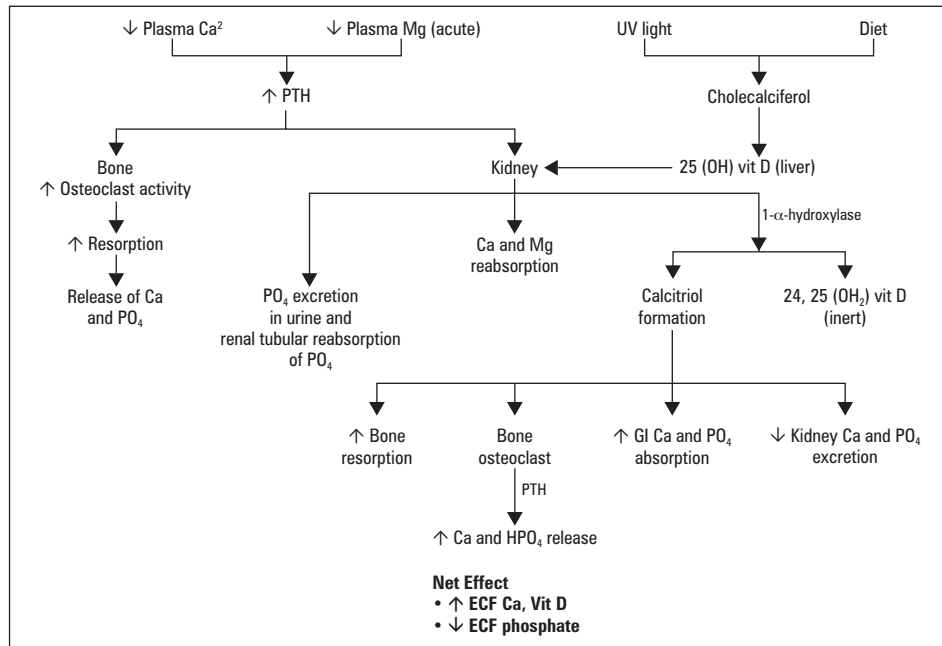

Figure 14. Parathyroid Hormone (PTH) Regulation

Vitamin D

- necessary for Ca and PO₄ absorption from GI tract
- cholecalciferol formed in the skin by the action of UV light

Calcitonin

- polypeptide secreted by thyroid C cells
- secretion enhanced by Ca, GI hormones, pentagastrin
- major actions
 - ↓ osteoclastic bone resorption (pharmacological effect)
 - ↑ renal PO₄ and Na clearance
 - acute net effect: ↓ serum Ca when given in pharmacologic doses

Magnesium

- major intracellular divalent cation
- Ca is reabsorbed from the kidney with Mg
 - thus Ca balance is difficult to maintain in Mg deficiency

Phosphorus

- intracellular cation
- found in all tissues and necessary for most biochemical processes as well as bone formation

Table 31. Summary of Effects

Hormone	Net Effect
Parathyroid Hormone (PTH)	Increased Ca Increased Vit D Decreased PO ₄
Vitamin D	Increased Ca Increased PO ₄
Calcitonin (in pharmacologic doses)	Decreased Ca

Pseudohypercalcemia: increased protein binding leading to an elevation in serum total Ca without a rise in the ionized/free form, e.g. hyperalbuminemia from severe dehydration.

Corrected Ca (mmol/L) = measured Ca + 0.02 (40 – albumin)

For every decrease in albumin by 10, increase in Ca by 0.2

Benign (less likely malignant):
Ca < 2.75 mmol/L (11 mg/dL)

Pathologic (more likely malignant):
Ca > 3.25 mmol/L (13 mg/dL)

Hypercalcemia

Definition

- total corrected serum Ca > 2.62 mmol/L (10.5 mg/dL) OR ionized Ca > 1.35 mmol/L (5.4 mg/dL)

Approach to Hypercalcemia (Figure 15)

1. Is the patient hypercalcemic? (correct for albumin – see sidebar)
2. Is the PTH high/normal or low?
3. If PTH is low, is phosphate high/normal or low? If phosphate is high/normal are the level of vitamin D metabolites high or low?

Increased Ca with High/Normal PTH		
Etiology	Risk Factors	Approach
Primary Hyperparathyroidism (#1 cause of hypercalcemia in outpatients) <ul style="list-style-type: none"> Solitary Adenoma 81% Hyperplasia 15% Carcinoma 4% MEN I and IIa 	<ul style="list-style-type: none"> Positive FMHx Hx of MEN/IIa Hx of childhood H+N radiation Postmenopausal women Normal physical exam 	<ul style="list-style-type: none"> Px: <ul style="list-style-type: none"> 50% asymptomatic (esp. with prolonged disease) Renal calculi, neuromuscular disease, low BMD Ix: serum Ca, PO_4, PTH, Imaging for renal calculi and osteoporosis Tx: surveillance vs. surgery
Tertiary Hyperparathyroidism	<ul style="list-style-type: none"> Renal failure Previous renal transplant 	<ul style="list-style-type: none"> Increased PTH after prolonged secondary hyperparathyroidism
Familial Hypocalciuric Hypercalcemia (FHH) <ul style="list-style-type: none"> Mutation in Ca sensing receptor gene → inappropriate PTH secretion and tubal Ca reabsorption 	<ul style="list-style-type: none"> Asymptomatic Hypocalciuric Positive FMHx (autosomal dominant) 	<ul style="list-style-type: none"> Ix: normal/mildly elevated PTH, low urinary Ca, normal 25-OH Vit D
Drug Induced <ul style="list-style-type: none"> Increased set point where PTH secretion is suppressed 	<ul style="list-style-type: none"> Lithium 	<ul style="list-style-type: none"> Ix: increased serum Ca with hypocalciuria

Figure 15. Differential Diagnosis of Hypercalcemia

Clinical Features

- symptoms depend on the absolute Ca value and the rate of its rise (may be asymptomatic)

Table 32. Symptoms of Hypercalcemia

Cardiovascular	GI	Renal	Rheumatological	MSK	Psychiatric	Neurologic
Hypertension	Constipation	Polyuria	Gout	Weakness	>3 mmol/L	Hypotonia
Arrhythmia	Anorexia	(Nephrogenic DI)	Pseudogout	Bone pain	(12 mg/dL)	Hyporeflexia
Short QT	Nausea	Polydipsia	Chondrocalcinosis	(bones)	Increased alertness	Myopathy
Deposition of Ca on valves, coronary arteries, myocardial fibres	Vomiting (groans)	Nephrolithiasis (stones)			Anxiety	Paresis
	PUD	Renal failure (irreversible)			Depression	
	pancreatitis				Cognitive dysfunction	
					Organic brain syndromes	
					>4 mmol/L (16 mg/dL)	
					Psychosis (moans)	

**** Hypercalcemia crisis (usually >4 mmol/L):** primary symptoms include oliguria/anuria and mental status changes (including somnolence and eventually coma) → this is a MEDICAL EMERGENCY and should be treated immediately!

Treatment

- treatment depends on the Ca level and the symptoms
- treat acute, symptomatic hypercalcemia aggressively

The most common cause of hypercalcemia in hospital is **malignancy-associated hypercalcemia**

- Usually occurs in the later stages of disease
- Most commonly seen in renal, breast, ovarian and squamous tumours, as well as lymphoma and multiple myeloma
- Mechanism: secretion of parathyroid hormone-related protein (PTHrP) which mimics PTH action by preventing renal calcium excretion and activating osteoclast-induced bone resorption

Primary hyperparathyroidism is the most common cause of hypercalcemia in healthy outpatients.

Differential Diagnosis of Hypercalcemia

1. Primary hyperparathyroidism
2. Malignancy: hematologic, humoral, skeletal metastases (>90% from 1 or 2)
3. Renal Disease: tertiary hyperparathyroidism
4. Drugs: calcium carbonate, milk-alkali syndrome, thiazide, lithium, theophylline, vitamin A/D intoxication
5. Familial hypocalciuric hypercalcemia
6. Granulomatous disease: sarcoidosis, TB
7. Thyroid disease: thyrotoxicosis
8. Adrenal disease: adrenal insufficiency, pheochromocytoma
9. Immobilization

Watch Out For:

- Volume depletion via diuresis
- Arrhythmias

The symptoms and signs of hypercalcemia include: **"Bones, stones, psychosis-based moans, and abdominal groans"**

Acute Management of Hypercalcemia/Hypercalcemic Crisis

1. Volume expansion (e.g. NS IV 300-500 cc/hr) – initial therapy
2. Calcitonin – transient, partial response
3. Bisphosphonate – treatment of choice
4. Corticosteroid – most useful in Vit D toxicity, granulomatous disease, some malignancies
5. Saline diuresis + loop diuretic (for volume overload) – temporary measure

Table 33. Treatment of Acute Hypercalcemia/Hypercalcemic Crisis

Increase Urinary Ca Excretion	Isotonic saline (4-5 L) ± loop diuretic (e.g. furosemide) but only if hypervolemic
Diminish Bone Resorption	Bisphosphonates (Tx of choice) <ul style="list-style-type: none"> • Inhibits osteoclastic bone resorption and promotes renal excretion of calcium • Acts rapidly but often transient response (decreased by 0.3-0.5 mmol/L (1.2-2.0 mg/dL) beginning within 4-6 hours) • Combination of calcitonin and steroids may prolong reduction in calcium • Tachyphylaxis may occur • Indicated in malignancy-related hypercalcemia, IV pamidronate is most commonly used 2-4 days until full effect but effect is long-lasting (2-4 weeks) Mithramycin (rarely used) – effective when patient cannot tolerate large fluid load <ul style="list-style-type: none"> ▪ Dangerous – hematotoxic and hepatotoxic
Decrease GI Ca Absorption	Corticosteroids in hypervitaminosis D and hematologic malignancies <ul style="list-style-type: none"> • Anti-tumour effects → decreased calcitriol production by the activated mononuclear cells in lung and lymph node • Slow to act (5-10 days); need high dose
Dialysis	
Chelation	EDTA or IV phosphate (rarely used) Oral phosphate in chronic hypercalcemia

Others

- prostaglandin inhibitors
- surgical treatment if indicated
- avoid immobilization

Hypocalcemia

Definition

- total corrected serum Ca <2.25 mmol/L (9.0 mg/dL)

Clinical Features

- most characteristic symptom is tetany

Differential Diagnosis of Tetany

- metabolic alkalosis (with hyperventilation)
- hypokalemia
- hypomagnesemia

Approach to Treatment

- correct underlying disorder
- mild/asymptomatic (ionized Ca >0.8 mmol/L, 3.2 mg/dL)
 - treat by increasing dietary Ca by 1000 mg/day
- acute/symptomatic hypocalcemia (ionized Ca <0.7 mmol/L, 2.8 mg/dL)
 - immediate treatment required
 - IV calcium gluconate 1-2 g in 10-20 mins followed by slow infusion if necessary
 - goal is to raise Ca to low normal range (2.0-2.1 mmol/L, 8.0-8.4 mg/dL) to prevent symptoms but allow maximum stimulation of PTH
- if PTH recovery not expected, requires long-term therapy with vitamin D and calcium
- do not correct hypocalcemia if it is suspected to be a transient response

Table 34. Clinical Features of Hypocalcemia

Acute Hypocalcemia	Chronic Hypocalcemia
Delirium	CNS: lethargy, seizures, psychosis, basal ganglia calcification, Parkinson's, dystonia,
Laryngospasm (with stridor)	hemiballismus, papilledema, pseudotumour cerebri
Paresthesia	CVS: prolonged QT interval
Hyperreflexia	GI: steatorrhea
Tetany	ENDO: impaired insulin release
Psychiatric Sx: emotional instability, anxiety and depression	SKIN: dry, scaling, alopecia, brittle and transversely fissured nails, moniliasis, abnormal dentition
Chvostek's sign (tap CNVII)	OCULAR: cataracts
Trousseau's sign (carpal spasm)	MSK: generalized muscle weakness and wasting

Signs and Symptoms of Acute Hypocalcemia

- **Paresthesias:** perioral, hands and feet
- **Chvostek's sign:** percussion of the facial nerve just anterior to the external auditory meatus elicits ipsilateral spasm of the orbicularis oculi or orbicularis oris muscles
- **Trousseau's sign:** inflation of a blood pressure cuff above systolic pressure for 3 minutes elicits carpal spasm and paresthesia

Approach to Hypocalcemia (Figure 16)

1. Is the patient hypocalcemic (correct for albumin)?
2. Is the PTH high or low?
3. If PTH is high, is phosphate low or normal?

Decreased Ca with Low PTH		
Iatrogenic Hypoparathyroidism	• Post-thyroidectomy, ¹³¹ I ablation, post surgical correction of primary hyperparathyroidism	
Primary Hypoparathyroidism	• Idiopathic/autoimmune hypoparathyroidism: DiGeorge syndrome, polyglandular autoimmune disease (acquired hypoparathyroidism ± adrenal insufficiency ± gonadal failure ± hypothyroidism and rarely hypopituitarism, diabetes insipidus, Type I DM) • Infiltrative diseases of parathyroid gland • HIV	
Secondary Hyperparathyroidism	Risk Factors • PT gland appropriately responds to low EC Ca, by ↑ absorption and ↑ bone resorption • Renal failure: low vit D synthesis • Low dietary Ca • GI malabsorption • Bisphosphonate use	Approach • Ix: increased PTH, normal/decreased serum Ca; renal function (Cr), Vit D/Ca sufficiency (25-OH Vit D, urinary Ca); GI w/u if high suspicion
Low Magnesium	• Under normal circumstances, low Mg stimulates PTH secretion • However, chronic low Mg is paradoxically associated with impaired PTH secretion • Low Mg levels also impair peripheral responsiveness to PTH • Drugs: antineoplastic agents (cisplatin, mithramycin) • Alcoholism	
Liver Dysfunction	• Hemochromatosis	
Pregnancy	• In pregnancy, there is a low total Ca due to hypoalbuminemia, but normal ionized level	
Decreased Ca with High PTH (Secondary Hyperparathyroidism)		
<div><div>↑ PTH</div><div><div>↓↓ phosphate</div><div>Vit D related</div><div><div>↓ Calcidiol</div><div>Decreased GI absorption (intake, liver/biliary) Phenytoin Nephrotic syndrome (lose Vit D binding protein)</div></div><div><div>↓ Calcitriol</div><div>Chronic renal failure Vit D dependent rickets type 1 (renal 1-alpha-hydroxylase deficiency)</div></div></div><div><div>Normal phosphate</div><div>Pseudohypoparathyroidism: PTH resistance secondary to G-protein deficiency Acute pancreatitis: release of pancreatic caldecrin decreases bone resorption Drugs: calcitonin, loop diuretics</div><div><div>↑ Calcitriol</div><div>Hereditary Vit D resistant rickets type II (receptor defect)</div></div></div></div>		

Figure 16. Etiology and Clinical Approach to Hypocalcemia

Hyperphosphatemia

Etiology

- increased intake
 - GI intake (rectal enema, GI bleeding)
 - IV phosphate load (K-Phos®, blood transfusion)
 - endogenous phosphate (tumour lysis syndrome, rhabdomyolysis, hemolysis)
- reduced renal clearance
 - ARF/CRF
 - hypoparathyroidism
 - acromegaly
 - tumour calcinosis (ability of kidney to specifically clear phosphate is defective)

Clinical Features

- non-specific, include ectopic calcification, renal osteodystrophy

Treatment

- low PO_4 diet, phosphate binders (e.g. CaCO_3)

Hypophosphatemia

Etiology

- inadequate intake
 - starvation
 - malabsorption (diarrhea, steatorrhea)
 - antacid use
 - alcoholism
- renal losses
 - hyperparathyroidism
 - diuretics
 - X-linked or AD hypophosphatemic rickets
 - Fanconi syndrome
- excessive skeletal mineralization
 - osteoblastic metastases
 - post parathyroidectomy (referred to as 'hungry bone syndrome')
- PO_4 shift into ICF
 - recovery from metabolic acidosis
 - respiratory alkalosis
 - starvation refeeding (stimulated by insulin)

Clinical Features

- non-specific (CHF, coma, hypotension, weakness)

Treatment

- treat underlying cause, supplement with oral PO_4 : 2-4 g/d divided bid-qid (start at 1000 mg/d to minimize diarrhea)

Hypermagnesemia

Etiology

- Mg-containing antacids given to those with severe renal failure
- IV administration of large doses of MgSO_4 (e.g. for pre-eclampsia; see [Obstetrics](#), OB14)

Clinical Features

- drowsiness, hyporeflexia, respiratory depression, decreased deep tendon reflexes

Treatment

- discontinue Mg-containing products

Hypomagnesemia

Etiology

- GI
 - starvation
 - malabsorption
 - vomiting
 - alcoholism
 - acute pancreatitis
- excess renal loss
 - 2° hyperaldosteronism due to cirrhosis and CHF
 - hyperglycemia
 - hypokalemia
 - hypercalcemia
 - diuretics

Clinical Features

- seizures, paresthesia, Chvostek and Trousseau signs

Treatment

- Mg IM/IV; cellular uptake of Mg is slow, therefore repletion requires sustained correction
- discontinue diuretics
 - in patients requiring diuretics, use a K-sparing diuretic to minimize magnesuria
- magnesium deficiency can aggravate potassium depletion by increasing distal potassium secretion, often refractory to treatment with potassium replacement
 - thus, important to check and correct magnesium levels prior to replacing potassium

Metabolic Bone Disease

Osteoporosis

Definition

- a condition characterized by decreased bone mass and microarchitectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to bone fracture

ETIOLOGY AND PATHOPHYSIOLOGY

Primary Osteoporosis

- due to post-menopausal decline in estrogen, worsens with age

Secondary Osteoporosis

- gastrointestinal diseases
 - gastrectomy
 - malabsorption
 - chronic liver disease
- bone marrow disorders
 - multiple myeloma
 - lymphoma
 - leukemia
- endocrinopathies
 - Cushing's syndrome
 - hyperparathyroidism
 - hyperthyroidism
 - premature menopause
 - diabetes
- malignancy
 - breast cancer
 - prostate cancer
- drugs
 - corticosteroid therapy → second most common cause of osteoporosis
 - individuals receiving ≥ 7.5 mg of prednisone daily for over 3 months should be assessed for bone-sparing therapy
 - mechanism: increased resorption + decreased formation
 - phenytoin
 - chronic heparin therapy
 - androgen deprivation therapy
 - aromatase inhibitors
- others
 - rheumatologic disorders
 - rheumatoid arthritis
 - SLE
 - ankylosing spondylitis
 - renal disease
 - poor nutrition
 - immobilization

Risk Factors

Table 35. Risk Factors for Osteoporosis

Major Risk Factors	Minor Risk Factors
<ul style="list-style-type: none"> Age >65 years Vertebral compression fracture Fragility fracture after age 40 Family history of osteoporotic fracture (especially maternal hip fracture) Propensity to fall (general frailty, poor balance, decreased visual acuity) Osteopenia apparent on x-ray film 	Lifestyle/Diet <ul style="list-style-type: none"> Smoking Excessive alcohol intake Excessive caffeine intake Low dietary calcium intake Weight <57 kg Weight loss >10% of weight at age 25
Secondary to Medical Disease <ul style="list-style-type: none"> Malabsorption syndrome Primary hyperparathyroidism 	Secondary to Medical Disease <ul style="list-style-type: none"> Rheumatoid Arthritis Past history of clinical hyperthyroidism
Drugs <ul style="list-style-type: none"> Systemic glucocorticoid therapy >3 months duration 	Drugs <ul style="list-style-type: none"> Chronic anticonvulsant therapy Chronic heparin therapy
Hormonal Deficiency <ul style="list-style-type: none"> Early menopause (before age 45) Hypogonadism 	

Use of Calcium or Calcium in Combination with vitamin D Supplementation to Prevent Fractures and Bone Loss in People aged 50 years and older: A Meta-Analysis

Lancet 2007; 370:657-66

Purpose: To determine whether supplementation with calcium or calcium in combination with vitamin D reduces fractures of all types and percentage change of bone-mineral density from baseline.

Study Selection: Randomized trials that recruited people aged 50 years or older.

Results: In trials that reported fracture as an outcome (17 trials, n=52,625), treatment was associated with a 12% risk reduction in fractures of all types (risk ratio 0.88, 95% CI 0.83-0.95; p=0.0004). In trials that reported bone-mineral density as an outcome (23 trials, n=41,419), the treatment was associated with a reduced rate of bone loss of 0.54% (0.35-0.73; p<0.0001) at the hip and 1.19% (0.76-1.61%; p<0.0001) in the spine. The fracture risk reduction was significantly greater (24%) in trials in which the compliance rate was high (p<0.0001). The treatment effect was better with calcium doses of 1200 mg or more than with doses less than 1200 mg (0.80 vs. 0.94; p=0.006), and with vitamin D doses of 800 IU or more than with doses less than 800 IU (0.84 vs. 0.87; p=0.03).

Conclusion: Evidence supports the use of calcium, or calcium in combination with vitamin D supplementation, in the preventive treatment of osteoporosis in people aged 50 years or older. For best therapeutic effect, we recommend minimum doses of 1200 mg of calcium, and 800 IU of vitamin D (for combined calcium plus vitamin D supplementation).

Bisphosphonates in Osteoporosis

NEJM 1995; 333:1437-43

Study: Randomized, blinded, placebo-controlled trial (3 year follow-up).

Patients: 994 post-menopausal women (mean 64 yrs, 87% white) with low BMD (t=-2.5). Exclusions included hx of glucocorticoid use, other disorders of bone, active PUD, and renal or hepatic insufficiency.

Intervention: Alendronate 5 mg, 10 mg, 20 mg, or placebo, each once daily. All received calcium 500 mg/day. In the 3rd year, women in the 20 mg group were blindly switched to 5 mg.

Main outcomes: Change in BMD, new vertebral fractures, and height.

Results: Women in all 3 alendronate groups had significant increases in BMD, while those in the placebo group had significant decreases. Women taking alendronate had fewer new vertebral fractures (RRR 52%, NNT 34, 95% CI 16 to 518), and a lower mean loss of height (p=0.005). There were no significant differences between groups for non-vertebral fractures, adverse effects, or discontinuation rates.

Conclusion: In post-menopausal women with osteoporosis, alendronate increased BMD, and reduced the risk of new vertebral fractures.

Calcium Content in Common Foods

	Standard Portion	Calcium (elemental)
Milk and Milk products		
Cheese – Brick, Cheddar, Colby, Edam, Gouda	1.75 oz/50 g	353 mg
Cheese – cottage, creamed, 2%, 1%	1/2 cup/125 mL	87 mg
Cheese – Mozzarella	1.75 oz/50 g	269 mg
Cheese – Swiss, Gruyère	1.75 oz/50 g	493 mg
Ice cream	1/2 cup/125 mL	93 mg
Milk – powder, dry	3 tbsp/45 mL	159 mg
Milk – whole, 2%, 1%, skim	1 glass/250 mL	315 mg
Yogourt	175 g	320 mg
Meat, fish, poultry and alternatives		
Almonds	1/2 cup/125 mL	200 mg
Beans – cooked	1 cup/250 mL	90 mg
Sardines, with bones	8 small	153 mg
Sesame seeds	1/2 cup/125 mL	100 mg
Soybeans – cooked	1 cup/250 mL	175 mg
Tofu – with calcium sulfate	1/2 cup/125 mL	130 mg
Breads and cereals		
Bread – white/wheat	1 slice/30 g	25 mg
Muffin – bran	1/35 g	50 mg
Fruits and vegetables		
Broccoli – raw	1/2 cup/125 mL	38 mg
Figs – dried	10	270 mg
Orange	1 medium/180 g	52 mg
Combination dishes		
Baked beans – canned	1 cup/250 mL	163 mg
Lasagna – homemade	1 cup/250 mL	286 mg
Soup made with milk	1 cup/250 mL	189 mg

Adapted from Health Canada: Canadian Nutrient File, 1991.

Clinical Signs of Fractures or Osteoporosis

1. Height loss > 3 cm (Sn 92%)
2. Weight < 51 kg
3. Kyphosis (Sp 92%)
4. Tooth count < 20 (Sp 92%)
5. Grip strength
6. Armspan-height difference > 5 cm (Sp 76%)
7. Wall-occiput distance > 0 cm (Sp 87%)
8. Rib-pelvis distance ≤ 2 finger breadth (Sn 88%)

Figure 17. Physical Examination Test

Clinical Features

- commonly asymptomatic
- collapsed vertebrae → height loss
- fractures
 - commonly occur in hip, vertebrae, humerus, and wrist
 - fragility fractures: fracture with fall from standing height
 - Dowager's hump = collapse fracture of vertebral bodies in mid-dorsal region
 - x-ray: vertebral compression and crush fractures, wedge fractures, "codfishing" sign (weakening of subchondral plates and expansion of intervertebral discs)
- pain, especially backache, associated with fractures

Investigations

- usually normal serum Ca, PO₄, alkaline phosphatase
- also measure 25(OH)-vit D, TSH, serum and urine protein electrophoresis, celiac workup and 24 hr urinary Ca excretion to r/o secondary causes
- densitometry
 - dual-energy x-ray absorptiometry (DEXA) – gold standard in diagnosis of osteoporosis, (quantitative CT, ultrasonography)
 - lumbar spine and femur
 - compared with gender and ethnicity-matched controls
 - osteopenia: bone mineral density 1.5-2.5 SD below mean
 - osteoporosis: >2.5 SD below mean

Screening: Who should we screen?

- DEXA for:
 - women and men ≥ 65 yr
 - postmenopausal women < 65 with risk factors
 - premenopausal women or men with fragility fractures of secondary causes
 - YES on risk assessment tools: SCORE questionnaire ≥ 6 or ORAI ≥ 9
 - ♦ if NO reassess in 1-2 years

Treatment of Osteoporosis

Table 36. Treatment of Osteoporosis in Women and Men

	Women	Men
Whom to Treat?	Postmenopausal: • T-score < -2.5 with no risk factors • T-score < -1.5 with ≥ 1 risk factors • Any spine or hip #	• > 65 with T-score < -2.5 at any site • > 50 with a fragility/vertebral compression #, OR any age with glucocorticoid therapy ≥ 3 mth OR any age with hypogonadism, AND T-score < -1.5
Lifestyle	Diet: Elemental calcium 1000-1500 mg/day; Vit D 800 IU/day Exercise: 3x30 min weight-bearing exercises/wk Cessation of smoking, reduce caffeine intake Stop/avoid osteoporosis-inducing medications	
Drug Therapy Bisphosphonate: Inhibitors of osteoclast binding	Alendronate, strontium, ranelate, risedronate, zoledronate, etidronate, pamidronate	
SERM (selective estrogen-receptor modulator): agonistic effect on bone but antagonistic effect on uterus and breast	Raloxifene: • +ve: prevents osteoporotic # (Grade A to B evidence), improves lipid profile, decreased breast ca risk • -ve: increased risk of DVT/PE, stroke mortality, hot flashes, leg cramps	
Parathyroid Hormone	YES fragility #: 18-24 mo duration	
Calcitonin (2nd line): osteoclast receptor binding	YES fragility #: Calcitonin 200 IU nasally OD with Calcitriol 0.25 µg BID	
HRT: combined estrogen + progesterone	For most women, risks > benefits • Combined estrogen/progestin prevents hip, vertebral, total # • Increased risks of breast ca and cardiovascular events	

Bisphosphonates are considered first-line treatment in women with established osteoporosis.

Alendronate for the Primary and Secondary Prevention of Osteoporotic Fractures in Postmenopausal Women
Cochrane Database Syst Rev 2008;(1):CD001155

Etidronate for the primary and secondary prevention of osteoporotic fractures in postmenopausal women
Cochrane Database Syst Rev. 2008;(1):CD003376.

Risedronate for the primary and secondary prevention of osteoporotic fractures in postmenopausal women
Cochrane Database Syst Rev. 2008;(1):CD004523.

Purpose: To assess the efficacy of three bisphosphonates in the primary and secondary prevention of osteoporotic fractures in postmenopausal women.
Study Selection: Women receiving at least one year of bisphosphonates for postmenopausal osteoporosis were compared to those receiving placebo or concurrent calcium/vitamin D or both. The outcome was fracture incidence.
Results: Levels of evidence: <http://www.cochraneskt.org/review/writing/>
%RRR and %ARR for 5 year fracture incidence reduction.

	Alendronate (10 mg/d)
1° Prevention - Vertebral	45% RRR, 2% ARR (Gold)
1° Prevention - Hip	Not significant
1° Prevention - Wrist	Not significant
2° Prevention - Vertebral	45% RRR, 6% ARR (Gold)
2° Prevention - Hip	53% RRR, 1% ARR (Gold)

1° Prevention - Wrist	Not significant
2° Prevention - Vertebral	39% RRR, 5% ARR (Gold)
2° Prevention - Hip	26% RRR, 1% ARR (Silver)
2° Prevention - Wrist	Not significant

Osteomalacia and Rickets

- **rickets** – osteopenia with disordered calcification leading to higher proportion of osteoid (unmineralized) tissue prior to epiphyseal closure (in childhood)
- **osteomalacia** – osteopenia with disordered calcification leading to higher proportion of osteoid (unmineralized) tissue after epiphyseal closure (in adulthood)

Etiology and Pathophysiology

Vitamin D Deficiency

- leads to secondary hyperparathyroidism and hypophosphatemia
- deficient uptake or absorption
 - nutritional deficiency
 - malabsorption: post-gastrectomy, small bowel disease (e.g. Celiac sprue), pancreatic insufficiency
- defective 25-hydroxylation
 - liver disease
 - anticonvulsant therapy
- loss of vitamin D binding protein
 - nephrotic syndrome
- defective 1-alpha-25 hydroxylation
 - hypoparathyroidism
 - renal failure

Mineralization Defect

- abnormal matrix
 - osteogenesis imperfecta
 - fibrogenesis imperfecta
 - axial osteomalacia
- enzyme deficiency
 - hypophosphatasia (inadequate ALP bioactivity)
- presence of calcification inhibitors
 - bisphosphonates, aluminum, high dose fluoride, anticonvulsants

Phosphate Deficiency

- decreased intake
 - antacids
- impaired renal reabsorption
 - primary defect: Wilson's syndrome, Fanconi syndrome, multiple myeloma
 - secondary defect: primary hyperparathyroidism, oncogenic osteomalacia

Factors Necessary for Mineralization

- Quantitatively and qualitatively normal osteoid formation
- Normal concentration of calcium and phosphate in ECF
- Adequate bioactivity of ALP
- Normal pH at site of calcification
- Absence of inhibitors of calcification

Table 37. Clinical Presentations of Rickets and Osteomalacia

Rickets	Osteomalacia
<ul style="list-style-type: none"> Skeletal pain and deformities, bow legged Fracture susceptibility Weakness and hypotonia Disturbed growth Ricketic rosary (prominent costochondral junctions) Harrison's groove (indentation of lower ribs) Hypocalcemia 	<ul style="list-style-type: none"> Not as dramatic Diffuse skeletal pain Bone tenderness Fractures Gait disturbances (waddling) Proximal muscle weakness Hypotonia

Investigations

Table 38. Laboratory Findings in Osteomalacia and Rickets

Disorder	Serum Phosphate	Serum Calcium	Serum ALP	Other Features
Vit D deficiency	Decreased	Decreased to normal	Increased	Decreased calcitriol
Hypophosphatemia	Decreased	Normal	Decreased to normal	
Proximal RTA	Decreased	Normal	Normal	Associated with hyperchloremic metabolic acidosis
Conditions associated with abnormal matrix formation	Normal	Normal	Normal	

- radiologic findings
 - pseudofractures, fissures, narrow radiolucent lines – thought to be healed stress fractures or the result of erosion by arterial pulsation
 - loss of radiologic distinctness of vertebral body trabecula, concavity of the vertebral bodies
 - changes due to secondary hyperparathyroidism: subperiosteal resorption of the phalanges, bone cysts, resorption of the distal ends of long bones
 - others: bowing of tibia, coxa profundus hip deformity
- bone biopsy
 - usually not necessary but considered the gold standard for diagnosis

Treatment

- depends on the underlying cause
- vitamin D supplementation
- PO₄ supplements if low serum PO₄ is present
- Ca supplements for isolated calcium deficiency
- bicarbonate if chronic acidosis

Renal Osteodystrophy

- represents a mixture of four types of bone disease
 - low turn-over osteomalacia – from acidosis and retention of toxic metabolites
 - osteoporosis – metabolic acidosis dissolution of bone buffers
 - osteitis fibrosa cystica – from increased PTH
 - osteosclerosis – from increased PTH
- metastatic calcification secondary to hyperphosphatemia may occur

Pathophysiology

- metabolic bone disease secondary to chronic renal failure
- combination of hyperphosphatemia (inhibits 1,25(OH)₂-vit D synthesis) and loss of renal mass (reduced 1-alpha-hydroxylase)

Clinical Features

- soft tissue calcifications → necrotic skin lesions if vessels involved
- osteodystrophy → generalized bone pain and fractures
- pruritus
- neuromuscular irritability and tetany may occur
- radiologic features of osteitis fibrosa cystica, osteomalacia, osteosclerosis, osteoporosis

Treatment

- prevention
 - maintenance of normal serum Ca and PO₄ by restricting PO₄ intake to 1 g OD
 - Ca supplements
 - PO₄ binding agents
 - prophylactic use of vitamin D with close monitoring to avoid hypercalcemia and metastatic calcification

Paget's Disease of Bone

Definition

- a metabolic disease characterized by excessive bone destruction and repair

Epidemiology

- a common disease: 5% of the population, 10% of population >80 years old

Etiology

- postulated to be related to a slow progressing viral infection of osteoclasts, possibly paramyxovirus
- strong familial incidence

Pathophysiology

- initiated by increased osteoclastic activity leading to increased bone resorption; osteoblastic activity increases in response to produce new bone that is structurally abnormal and fragile

Differential Diagnosis

- primary bone lesions
 - osteogenic sarcoma
 - multiple myeloma
 - fibrous dysplasia
- secondary bone lesions
 - osteitis fibrosa cystica
 - metastases

Clinical Features

- usually asymptomatic (routine x-ray finding or elevated alkaline phosphatase)
- severe bone pain (e.g. pelvis, femur, tibia) is often the presenting complaint
- skeletal deformities – bowed tibias, kyphosis, frequent fractures
- skull involvement – headaches, increased hat size, deafness
- increased warmth over involved bones due to increased vascularity

Investigations

- laboratory
 - serum alkaline phosphatase is usually very high (unless burnt out)
 - normal or increased serum Ca
 - normal serum PO_4
 - increased urinary hydroxyproline (indicates resorption)
- imaging
 - evaluate the extent of disease with bone scan
 - initial lesion may be destructive and radiolucent
 - involved bones are expanded with cortical thickening and denser than normal
 - multiple fissure fractures in long bones

Complications

- local
 - fractures
 - osteoarthritis
 - cranial nerve compression and palsies, e.g. deafness
 - spinal cord compression
 - osteosarcoma/sarcomatous change
 - ♦ 1 to 3%
 - ♦ indicated by marked bone pain, new lytic lesions and sudden increased alkaline phosphatase
- systemic
 - hypercalcemia and nephrolithiasis
 - high output congestive heart failure due to increased vascularity

Treatment

- symptomatic therapy
- treat if ALP >3x normal
- bisphosphonates, e.g. alendronate 40 mg PO OD x 6 months OR risendronate 30 mg PO OD x 3 months OR zoledronic acid 5 mg IV per year
- calcitonin 50-100 U/day subcutaneous injection
- adequate calcium and vitamin D intake to prevent development of secondary hyperparathyroidism

Comparison of a Single Infusion of Zoledronic Acid with Risedronate for Paget's Disease

NEJM 2005; 353:898-908

Study: Two identical, randomized, double-blind, actively controlled trials (combined for analysis).

Patients: 357 men and women who were older than 30 years of age and had radiologically confirmed Paget's disease of bone. All but 4 patients had alkaline phosphatase levels that were more than twice the upper limit of normal.

Intervention: One 15-minute infusion of 5 mg of zoledronic acid with 60 days of oral risedronate (30 mg per day) with follow up at 6 months.

Primary Outcome: Rate of therapeutic response at six months, defined as a normalization of alkaline phosphatase levels or a reduction of at least 75 percent in the total alkaline phosphatase excess.

Results: At six months, 96.0 percent of patients receiving zoledronic acid had a therapeutic response (169 of 176), as compared with 74.3 percent of patients receiving risedronate (127 of 171, $P < 0.001$). Alkaline phosphatase levels normalized in 88.6 percent of patients in the zoledronic acid group and 57.9 percent of patients in the risedronate group ($P < 0.001$). Zoledronic acid was associated with a shorter median time to a first therapeutic response (64 vs. 89 days, $P < 0.001$). Higher response rates in the zoledronic acid group were consistent across all demographic, disease-severity, and treatment-history subgroups and with changes in other bone-turnover markers. The physical-component summary score of the Medical Outcomes Study 36-item Short-Form General Health Survey, a measure of the quality of life, increased significantly from baseline at both three and six months in the zoledronic acid group and differed significantly from those in the risedronate group at three months. Pain scores improved in both groups. During post-trial follow-up (median, 190 days), 21 of 82 patients in the risedronate group had a loss of therapeutic response, as compared with 1 of 113 patients in the zoledronic acid group ($P < 0.001$).

Conclusions: A single infusion of zoledronic acid produces more rapid, more complete, and more sustained responses in Paget's disease than does daily treatment with risedronate.

Male Reproductive Endocrinology

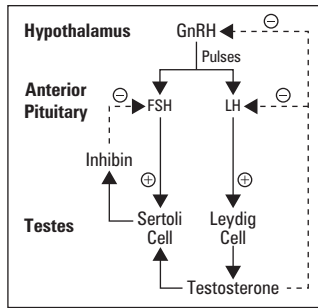

Figure 18. Hypothalmo-Pituitary-Gonadal Axis

Androgen Regulation

- both positive and negative feedback may occur by androgens directly or after conversion to estrogen
- testosterone (from the Leydig cell) primarily involved in negative feedback on LH, whereas inhibin (from the Sertoli cell) suppresses FSH secretion

Tests of Testicular Function

- testicular size (lower limit = 4 cm x 2.5 cm)
- LH, FSH, testosterone
- human chorionic gonadotropin (hCG) stimulation test
 - assesses ability of Leydig cell to respond to gonadotropin
- semen analysis
 - semen volume, sperm count, morphology and motility
- testicular biopsy
 - indicated in the context of normal FSH and azoospermia/oligospermia

Hypogonadism and Infertility

- see Urology, U34
- deficiency in gametogenesis or testosterone production

Etiology

- causes include primary (testicular failure) and secondary (hypothalamic-pituitary failure)
- primary hypogonadism is more common than secondary

Table 39. Classification and Features of Hypogonadism

	Hypergonadotropic Hypogonadism (Primary Hypogonadism)	Hypogonadotropic Hypogonadism (Secondary Hypogonadism)
Definition	Primary testicular failure ↑ LH and FSH, ↑ FSH:LH ratio ↓ testosterone and sperm count	Hypothalamic-pituitary axis failure ↓ LH + FSH ↓ testosterone and sperm count
Etiology	Congenital: <ul style="list-style-type: none"> • Chromosomal defects (Klinefelter's, Noonan) • Cryptorchidism • Male pseudohermaphroditism • Bilateral anorchia (vanishing testicle syndrome) • Myotonic dystrophy • Mutation of FSH or LH receptor gene • Varicocele • Disorders of androgen synthesis Germ cell defects <ul style="list-style-type: none"> • Sertoli cell only syndrome • Leydig cell aplasia/failure Infection/ Inflammation <ul style="list-style-type: none"> • Orchitis – TB, lymphoma, mumps, leprosy • Genital tract infection Physical factors <ul style="list-style-type: none"> • Trauma, heat, irradiation, testicular torsion Drugs <ul style="list-style-type: none"> • Marijuana, alcohol, chemotherapy, ketoconazole, glucocorticoid Autoimmune	Congenital <ul style="list-style-type: none"> • Kallman's syndrome • Prader-Willi syndrome • Abnormal subunit of LH or FSH Infection <ul style="list-style-type: none"> • Tuberculosis, meningitis Endocrine <ul style="list-style-type: none"> • Adrenal androgen excess • Cushing's syndrome • Hypo or hyperthyroidism • Hypothalamic-pituitary disease (tumour, hyperprolactinemia, hypopituitarism) Drugs <ul style="list-style-type: none"> • Alcohol, marijuana, spironolactone, ketoconazole, GnRH agonists, androgen/estrogen/progestin use, chronic narcotic use Chronic illness <ul style="list-style-type: none"> • Cirrhosis, chronic renal failure, AIDS • Sarcoidosis, Langerhan's cell histiocytosis, hemochromatosis Critical illness <ul style="list-style-type: none"> • Surgery, MI, head trauma Idiopathic
Diagnosis	Sperm count LH, FSH, testosterone hCG stimulation Testicular size and consistency (soft/firm) Karyotype	Sperm count LH, FSH, testosterone Prolactin levels MRI of hypothalamic-pituitary region

Two Distinct Features of Primary Hypogonadism

1. The decrease in sperm count is affected to a greater extent than the decrease in serum testosterone level
2. Likely to be associated with gynecomastia

Two Features of Secondary Hypogonadism

1. Associated with an equivalent decrease in sperm count and serum testosterone
2. Less likely to be associated with gynecomastia

Treatment

- testosterone replacement (improve libido, muscle mass, strength, hair growth)
 - IM injection, transdermal testosterone patch/gel
 - side effects: acne, fluid retention, erythrocytosis, sleep apnea (rare)
 - contraindicated if history of prostate cancer
- GnRH agonist to restore fertility
 - administered SC in pulsatile fashion using an external pump
- surgery – only if testicular tissues are not functioning

Causes of Male Infertility

1. primary hypogonadism
2. secondary hypogonadism
3. other causes:
 - autoimmune disorders – sperm antibody
 - anatomy – hypospadias, retrograde ejaculation
 - sexual dysfunction – erectile dysfunction, premature ejaculation, infrequent coitus
 - obstruction – vasal occlusion, vasal aplasia, vasectomy, seminal vesicle disease

DEFECTS IN ANDROGEN ACTION**Etiology**

- complete androgen insensitivity (testicular feminization)
- incomplete androgen insensitivity
 - 5-alpha-reductase deficiency
 - mixed gonadal dysgenesis
 - defects in testosterone synthesis
- infertile male syndrome
- undervirilized fertile male syndrome

Clinical Features

- depends on age of onset

Table 40. Effects of Testosterone Deficiency

First trimester in utero	Incomplete virilization of external genitalia (ambiguous genitalia) Incomplete development of Wolffian ducts to form male internal genitalia (male pseudohermaphroditism)
Third trimester in utero	Micropenis Cryptorchidism (failure of normal testicular descent)
Prepuberty	Incomplete pubertal maturation (high pitch voice, sparse pubic + axillary hair, absence of facial hair) Eunuchoidal body habitus (greater growth of extremity long bones relative to axial bones) Poor muscle development, reduced peak bone mass
Postpuberty	Decrease in energy, mood, and libido Fine wrinkles in corners of mouth and eyes Decrease in sexual hair, hematocrit, muscle mass, strength and bone mineral density

Adapted from UpToDate, 2010 + Cecil's Essentials of Medicine

Treatment

- appropriate gender assignment in the newborn
- hormone replacement or supplementation
- psychological support
- gonadectomy for cryptorchidism (due to increased risk for testicular cancer)
- reduction mammoplasty for gynecomastia

**Approach to Male Infertility****History**

- Partner status re: infertility
- Length of time for attempt to conceive
- Prior successes with other partners
- Ejaculation problems
- Frequency of intercourse
- Prev Surg, Med Hx, STD Hx
- Hx orchitis? Cryptorchidism?
- Hx toxic exposure?
- Medications
- Alcohol and illicit drug use
- Heat exposure: bath, sauna, whirlpool
- Smoking

P/E

- Testicular size and consistency
- Varicocele?
- Pituitary disease?
- Thyroid disease?

Investigations

- Semen analysis x 2 (sperm count, morphology, motility)
- Scrotal/Testicular U/S (look for varicocele)
- Bloodwork: LH, FSH, Testosterone, Prolactin, TFT's, DNA fragmentation of sperm, Karyotype, Y chromosome deletion

Treatment

- No specific therapy for majority of cases
- Treat specific causes
- Consider: intrauterine insemination, IVF, therapeutic donor insemination, testicular aspiration of sperm, adoption

Erectile Dysfunction

- see Urology, U30

**Epidemiology of Gynecomastia****Occurrence of Gynecomastia****3 peaks % affected**

Endocrine

CHronic disease

Gynecomastia

Definition

- true gynecomastia refers to benign proliferation of the glandular component of the male breast, resulting in the formation of a concentric, rubbery, firm mass extending from the nipple(s)
- pseudogynecomastia or lipomastia refers to enlargement of soft adipose tissue, especially seen in obese individuals and does not warrant further evaluation

Etiology**Physiologic**

- puberty
- elderly (involutional)
- neonatal (maternal hormone)

Pathologic

- endocrinopathies – primary or secondary hypogonadism, hyperthyroidism, extreme hyperprolactinemia, adrenal disease
- tumours – pituitary, adrenal, testicular, breast
- chronic diseases – liver, renal, malnutrition (with refeeding)
- drugs – estrogens and estrogen agonists, spironolactone, ketoconazole, cimetidine, digoxin, chemotherapy, marijuana, alcohol
- congenital/genetic – Klinefelter's syndrome, androgen insensitivity
- other – idiopathic, familial

Pathophysiology

- decreased androgen production + increased estrogen production
- increased availability of estrogen precursors for peripheral conversion to estrogen
- androgen receptor blockage + binding of androgen to sex hormone binding globulin (SHBG)

History

- recent change in breast characteristics
- history of trauma to testicles
- history of mumps
- alcohol and/or drug use
- family history
- sexual dysfunction

Physical Exam

- signs of feminization
- breast
 - must differentiate from breast cancer (unilateral, eccentric, hard/firm mass, fixed to underlying tissue) with possible skin changes (dimpling, retraction) or nipple changes (discharge, crusting)
 - gynecomastia in contrast occurs concentrically around nipple, and is not fixed to underlying tissue
- genito-urinary exam
- stigmata of liver or thyroid disease

Investigations

- laboratory – serum TSH, PRL, LH, FSH, free testosterone, estradiol, LFTs, creatinine, hCG (if hCG is elevated, need to locate the primary tumour)
- CXR and CT of chest/abdomen/pelvis (to locate neoplasm)
- testicular U/S to rule out testicular mass
- MRI of hypothalamic-pituitary region

Treatment

- medical
 - correct the underlying disorder, discontinue responsible drug
 - androgens for hypogonadism
 - anti-estrogens – tamoxifen, clomiphene
- surgical
 - usually required if have macromastia; gynecomastia present for >1 year (fibrosis is unresponsive to medication); or failed medical treatment and for cosmetic purposes

Common Medications

Diabetes Medications

Drug Class	Mechanism of Action	Generic Drug Name	Canada Name	US Name (if different)	Dosing	Indications	Contraindications	Side Effects	Comments	
Biguanide	<ul style="list-style-type: none">• Sensitizes peripheral tissues to insulin → increases glucose uptake• Decreases hepatic glucose production	metformin	Glucophage® Glumetza®		500 mg OD titrated to 1000 mg bid maximum	<ul style="list-style-type: none">• Useful in obese Type 2 DM• Improves both fasting and postprandial hyperglycemia• Also ↓ TG	ABSOLUTE: <ul style="list-style-type: none">• Moderate to severe liver dysfunction• Moderate renal dysfunction• Cardiac dysfunction	<ul style="list-style-type: none">• GI upset (abdo discomfort, bloating, diarrhea)• Lactic acidosis• Anorexia	↓ HbA1C 1.0-1.5%

Dyslipidemia Medications

Drug Class	Mechanism of Action	Generic Drug Name	Canada Name	US Name (if different)	Dosing	Indications	Contraindications	Side Effects
HMG CoA reductase inhibitor	• Inhibits cholesterol biosynthesis, ↓ LDL synthesis, ↑ LDL clearance, modest ↑ HDL, limited ↓ VLDL	atorvastatin fluvastatin lovastatin pravastatin rosuvastatin simvastatin	Lipitor® Lescol® Mevacor® Pravachol® Crestor® Zocor®		10-80 mg/day 20-80 mg/day 20-80 mg/day 10-40 mg/day 5-40 mg/day 10-80 mg/day	• 1 st line monotherapy • Used for ↑ LDL, ↑ TG	• Active liver disease • Persistent ↑ in AST, ALT	• GI symptoms • Rash, pruritus • ↑ liver enzymes • Myositis (↑ risk if combined with fibrates) • Rhabdomyolysis (dose >80 mg)
Fibrates	• Upregulate lipoprotein lipase + Apo A1, ↓ VLDL, ↓ TG, modest ↓ LDL, modest ↑ HDL	bezafibrate fenofibrate gemfibrozil	Bezalip® Lipidil® Lopid®		400 mg/day 48-200 mg/day 600-1200 mg/day	• Used for ↑ TG, hyperchylomicronemia	• Hepatic disease • Renal disease	• GI upset • ↑ risk of gallstone formation • ↑ risk of rhabdomyolysis when combined with statins
Niacin	• Inhibits secretion of hepatic VLDL via lipoprotein lipase (LPL) pathway → decreased VLDL and LDL; decreased clearance of HDL	nicotinic acid	Niaspan® generic niacin	Niacor®	0.5-2 g/day 1-3 g/day	• Used for ↑ LDL, ↑ VLDL	• Hypersensitivity • Hepatic dysfunction • Active PUD • Overt DM • Hyperuricemia	• Generalized flushing • Abnormal liver enzymes • Pruritus • IGT • Severe hypertension
Bile acid sequestrants	• Resins that bind bile acids in intestinal lumen and prevent absorption thereby ↓ LDL	cholestyramine	Questran® Prevalite®		2-24 g/day	• Used for ↑ LDL • Use as adjunct with statins or fibrates	• Complete biliary obstruction • Pregnancy, lactation • TG > 300 mg/dL • GI motility disorder	• Constipation • Nausea • Flatulence • Bloating
Cholesterol absorption inhibitors	• Inhibits cholesterol absorption at the small intestine brush border	colesevelam	Colestid® Ezetrol®	Zetia®	5-30 g/day 10 mg/day	• Used for ↑ LDL, Apo B	• Hypersensitivity • Hepatic dysfunction • Don't combine with fibrates or bile acid resins	• Fatigue • Pharyngitis • Sinusitis • Abdominal pain • Diarrhea • Arthralgia

Thyroid Medications

Drug Class	Mechanism of Action	Generic Drug Name	Canada Name	US Name (if different)	Dosing	Indications	Contraindications	Side Effects
Antithyroid Agent	• Decreases thyroid hormone production by inhibiting iodine and peroxidase from interacting with thyroglobulin to form T ₄ and T ₃ • Also interferes with conversion of T ₄ to T ₃	propylthiouracil (PTU)	Propyl-Thyracil® Tapazole®		Start 100 mg PO tid, then adjust accordingly Thyroid storm: start 200-300 PO qid, then adjust accordingly	• Hyperthyroidism	• Hypersensitivity • Relative: renal failure, liver disease	• Nausea, vomiting • Rash • Drug-induced hepatitis • Agranulocytosis
		methimazole (MMI)			Start 5-20 mg PO OD, then adjust accordingly		• Pregnancy, lactation	• Hepatitis
Thyroid hormone	• Synthetic form of thyroxine (T ₄)	levothyroxine l-thyroxine	Synthroid® Levothroid® Unithroid®	Levoxyl®	0.05-2.0 mg/day, in elderly patients start at 0.025 mg/day	• Hypothyroidism	• Recent MI, thyrotoxicosis	• Symptoms of hyperthyroidism • Tachycardia • Angina • Weight loss • Hyperthermia • Diarrhea • Insomnia • Tremors • Muscle weakness

Metabolic Bone Disease Medications

Drug Class	Mechanism of Action	Generic Drug Name	Canada Name	US Name (if different)	Dosing	Indications	Contraindications	Side Effects
Bisphosphonates	<ul style="list-style-type: none"> Inhibits osteoclast-mediated bone resorption 	alendronate	Fosamax®		5-10 mg OD 70 mg once weekly 40 mg OD for 6 months	<ul style="list-style-type: none"> Prevention of postmenopausal osteoporosis Treatment of osteoporosis Glucocorticoid-induced osteoporosis Paget's disease 	<ul style="list-style-type: none"> Esophageal stricture or achalasia (oral) Unable to stand or sit upright for >30 min (oral) Hypersensitivity Hypocalcemia Renal insufficiency 	<ul style="list-style-type: none"> GI MSK pain Headache Osteonecrosis of the jaw
		risatronate	Actonel®		5 mg OD 35 mg once weekly 150 mg once monthly 30 mg OD for 2 months	<ul style="list-style-type: none"> Treatment and prevention of postmenopausal osteoporosis Treatment and prevention of glucocorticoid-induced osteoporosis Paget's disease 		
		etidronate	Didronel®		5-10 mg/kg OD x 6 months	<ul style="list-style-type: none"> Osteoporosis Symptomatic Paget's disease Prevention and treatment of heterotopic ossification after total hip replacement or spinal cord injury 		
		ibandronate	Boniva®		2.5 mg OD or 150 mg once monthly	<ul style="list-style-type: none"> Treatment and prevention of postmenopausal osteoporosis (US only) 		
		panidronate	Aredia®		IV	<ul style="list-style-type: none"> Hypercalcemia of malignancy Paget's disease Osteolytic bone metastases of breast cancer Osteolytic lesions of multiple myeloma 		
		zoledronate	Zometa® Aclasta®		5 mg IV once yearly IV	<ul style="list-style-type: none"> Treatment of osteoporosis Hypercalcemia of malignancy Treatment and prevention of skeletal complications related to cancer 		
Selective Estrogen Receptor Modulators	<ul style="list-style-type: none"> Decreases resorption of bone through binding to estrogen receptors 	raloxifene	Evista®		60 mg OD	<ul style="list-style-type: none"> Treatment and prevention of postmenopausal osteoporosis (2nd line) 	<ul style="list-style-type: none"> Lactation Pregnancy Active or past history of DVT, PE or retinal vein thrombosis 	<ul style="list-style-type: none"> Hot flashes Leg cramps Increased risk of fatal stroke, venous thromboembolism
Calcitonin	<ul style="list-style-type: none"> Inhibits osteoclast-mediated bone resorption 	salcatonin	Miacalcin®		One spray (200 IU) per day, alternating nostrils	<ul style="list-style-type: none"> Treatment of postmenopausal osteoporosis, greater than 5 years postmenopause 	<ul style="list-style-type: none"> Clinical allergy to calcitonin-salmon 	<ul style="list-style-type: none"> Rhinitis Epistaxis Sinusitis Nasal dryness
PTH	<ul style="list-style-type: none"> Stimulates new bone formation by preferential stimulation of osteoblastic activity over osteoclastic activity 	teriparatide	Forteo®		20 µg SC OD X 18-24 months	<ul style="list-style-type: none"> Treatment of postmenopausal women with osteoporosis who are at high risk for fracture Treatment of men with primary or hypogonadal osteoporosis who are at high risk for fracture 	<ul style="list-style-type: none"> Paget's disease Prior external beam or implant radiation therapy involving the skeleton Bone metastases Metabolic bone diseases other than osteoporosis 	<ul style="list-style-type: none"> Orthostatic hypotension Hypercalcemia Dizziness Leg cramps

Metabolic Bone Disease Medications (continued)

Drug Class	Mechanism of Action	Generic Drug Name	Canada Name	US Name (if different)	Dosing	Indications	Contraindications	Side Effects
Calcium	• Inhibits PTH secretion				1500 mg/day (including diet) Divide in 3 doses	• Osteopenia • Osteoporosis • Prevention of metabolic bone disease	• Caution with renal stones	• Vomiting • Constipation • Dry mouth
Vitamin D	• Regulation of calcium and phosphate homeostasis	cholecalciferol (vitamin D3)			800 IU/day	• Osteopenia • Osteoporosis • Prevention of metabolic bone disease	• Caution in patients on digoxin (risk of hypercalcemia may precipitate arrhythmia)	• Hypercalcemia • Headache • Nausea, vomiting • Constipation
		ergocalciferol (vitamin D2)	Osteoforte® Deltalin®		50000 IU	• Osteoporosis in patients with liver dysfunction, refractory rickets, hypoparathyroidism	• Hypercalcemia • Malabsorption syndrome • Decreased renal function	
		calcitriol (1,25(OH) ₂ -D)	Rocaltrol® Calcijex®		Start 0.25 µg/day Titrate up by 0.25 µg/day at 4-8 week intervals to 0.5-1 µg/day	• Hypocalcemia and osteodystrophy in patients with chronic renal failure on dialysis	• Hypercalcemia • Vitamin D toxicity	
					Start 0.25 µg/day Titrate up by 0.25 µg/day at 2-4 week intervals to 0.5-2 µg/day	• Hypoparathyroidism		

Adrenal Medications

Drug Class	Mineralocorticoid Activity	Generic Drug Name	Potency (relative to Cortisol)	Equivalent Dose (mg)	Duration of Action (t 1/2 in hours)	Dosing	Comments
Hydrocortisone	Yes	Cortef Solu-Cortef	1.0	20	8	Adrenal Crisis: 100 mg IV bolus, then 100 mg q 8 hr (continuous infusion x 24-48 hr) PO once stable (50 mg q 8hr x 48 hrs, then taper over 14 d) Chronic AI: 20-30 mg PO OD (2/3 AM, 1/3 PM)	• In high doses, mineralocorticoid side effects may emerge salt + water retention, ECF volume expansion, HTN, low K metabolic alkalosis
Cortisone acetate	Yes	Cortone Acetate	0.8	25	oral = 8 IM = 18 +	Adrenal Crisis: 25-300 mg/d PO/IM divided q12-24 hr Chronic AI: 25-35 mg/d	• Pro-drug which is converted to active form as hydrocortisone • High doses can result in mineralocorticoid side effects (see above)
Prednisone	No	Deltasone Liquid Pred	3.5	6	16-36	Adrenal Crisis: 5-60 mg/d PO qd or divided BID/QID	• Pro-drug which is converted to active form as prednisolone
Dexamethasone	No	Decadron AK-Dex Dexone	30	0.7	36-54	Adrenal Crisis: 4 mg IV; repeat q2-6 hr if necessary	• Used for undiagnosed adrenal insufficiency (won't interfere with serum cortisol levels)

Landmark Endocrinology Trials

Trial	Reference	Results
DIABETES		
DCCT	<i>NEJM</i> 1993; 329:977-86	Intensive blood glucose control delayed the onset and reduced the progression of microvascular complications (retinopathy, nephropathy and neuropathy) in Type 1 DM
UKPDS	<i>Lancet</i> 1998; 352:837-53	Intensive blood glucose control reduces microvascular, but not macrovascular complications in Type 2 DM
EDIC	<i>NEJM</i> 2005; 353:2644-53	Compared with conventional therapy, intensive diabetes therapy (goal HbA1C <6.05%) has long-term beneficial effects on the risk of cardiovascular disease in patients with Type 1 DM
ACCORD	<i>NEJM</i> 2008; 358:2560-72	Compared with standard therapy, the use of intensive therapy to target normal HbA1c levels for 3.5 years increased mortality and did not significantly reduce major cardiovascular events
ADVANCE	<i>NEJM</i> 2008; 358:2545-59	Intensive glucose control that lowered the HbA1C value to 6.5% reduced the incidence of nephropathy but did not significantly reduce major macrovascular events, death from cardiovascular events, or death from any cause. Hypoglycemia was more common in the intensive control group
VADT	<i>NEJM</i> 2009; 360:1-11	In patients with longstanding poorly controlled Type 2 DM, intensive glucose control had no significant effect on the rates of major cardiovascular events, death, or microvascular complications. Adverse events, predominantly hypoglycemia, were more common in the intensive control group
BARI-2D	<i>NEJM</i> 2009; 360:2503-15	In patients with both Type 2 DM and coronary artery disease, no significant difference was found in the rates of death and major cardiovascular events in patients undergoing prompt revascularization and those undergoing medical therapy or between strategies of insulin sensitization and insulin
Steno-2	<i>NEJM</i> 2008; 358:580-91	In at-risk patients with Type 2 DM, intensive intervention with multiple drug combinations and behaviour modification had sustained significant beneficial effects with respect to vascular complications and mortality. Multifactorial intervention is critical in the management of Type 2 DM
NAVIGATOR	<i>NEJM</i> 2010; 362:1463-90	In patients with impaired glucose tolerance, nateglinide did not reduce progression to diabetes or risk of cardiovascular events, while valsartan only reduced progression to diabetes
LIPIDS		
4S	<i>Lancet</i> 1994; 344:1383-89	In patients with angina or previous MI and high total cholesterol, simvastatin reduced: all-cause mortality, fatal and nonfatal coronary events, and need for coronary artery bypass surgery or angioplasty
HPS	<i>Lancet</i> 2002; 360:7-22	In high-risk patients with various cholesterol values, simvastatin reduced all-cause mortality, coronary deaths and major vascular events
TNT	<i>NEJM</i> 2005; 352:1425-35	Lipid-lowering therapy with atorvastatin 80 mg/day in patients with stable CHD provides clinical benefit beyond atorvastatin 10 mg/day
FIELD	<i>Lancet</i> 2005; 366:1849-61	In patients with Type 2 DM, not previously on statin therapy, fenofibrate did not significantly reduce the risk of the primary outcome of coronary events. It did reduce non-fatal myocardial infarctions and revascularizations
Jupiter	<i>NEJM</i> 2008; 359:2195-207	Rosuvastatin significantly reduced the incidence of major cardiovascular events in patients with elevated high-sensitivity C-reactive protein levels and no hyperlipidemia

**Patient-Centred Clinical Method**

- Explore/define patient problems and decide on management together
- Consider both agendas and find common ground

**Agendas in Family Medicine****Doctor's Agenda**

History, physical, investigation, diagnosis, plan

Patient's Agenda**FIFE**

Feelings

Ideas

Function

Expectations

Four Principles of Family Medicine

College of Family Physicians of Canada Guidelines**1. The family physician is a skilled clinician**

- in diagnosing and managing diseases common to population served
- recognizes importance of early diagnosis of serious life-threatening illnesses

2. Family medicine is a community-based discipline

- provides information and access to community services
- responds/adapts to changing needs and circumstances of the community

3. The family physician is a resource to a defined practice population

- serves as a health resource
- advocates for public policy to promote health

4. The patient-physician relationship is central to the role of the family physician

- committed to the person, not just the disease
- promotes continuity of patient care

Periodic Health Examination (PHE)

- Canadian Task Force on Preventive Health Care established in 1976, first published in 1979, last updated in 2005
- mandate: to develop and disseminate clinical practice guidelines for primary and preventive care
- recommendations are based on systemic analysis of scientific evidence
 - most notable recommendation is the abolition of the annual physical exam; replaced by the PHE

Purpose of the PHE

- primary prevention: identify risk factors for common diseases; counsel patients to promote healthy behaviour
- secondary prevention: presymptomatic detection of disease to allow early treatment and to prevent disease progression
- update clinical data
- enhance patient-physician relationship

**Adult Periodic Health Exam**

Male and female evidence-based preventative care checklist forms are available online at www.cfpc.ca.

**Classification of Recommendations**

- A Good** evidence to recommend the clinical preventative action.
- B Fair** evidence to recommend the clinical preventative action.
- C** Existing evidence is **conflicting** and does not allow to make a recommendation for or against use of the clinical preventative action; however, other factors may influence decision-making.
- D Fair** evidence to recommend **against** the clinical preventative action.
- E Good** evidence to recommend **against** the clinical preventative action.
- I Insufficient** evidence (in quantity or quality) to make a recommendation; however, other factors may influence decision-making.

Table 1. Periodic Health Exam

	General Population	Special Population
DISCUSSION	<ul style="list-style-type: none"> • Dental hygiene (community fluoridation, brushing, flossing) (A) • Noise control and hearing protection (A) • Smokers: counsel on smoking cessation, provide <ul style="list-style-type: none"> • Nicotine replacement therapy (A) • Referral to smoking cessation program (B) • Dietary advice on leafy green vegetables and fruits (B) • Seat belt use (B) • Injury prevention (bicycle helmets, smoke detectors) (B) • Moderate physical activity (B) • Avoid sun exposure and wear protective clothing (B) • Problem drinking screening and counselling (B) • Counselling to protect against STIs (B) • Nutritional counselling and dietary advice on fat and cholesterol (B) 	<p>Pediatrics: Home visits for high risk families (A) Inquiry into developmental milestones (B)</p> <p>Adolescents: Counsel on sexual activity and contraceptive methods (B) Counsel to prevent smoking initiation (B)</p> <p>Perimenopausal women: Counsel on osteoporosis Counsel on risks/benefits of hormone replacement therapy (B)</p> <p>Adults > 65: Follow-up on caregiver concern of cognitive impairment (A) Multidisciplinary post-fall assessment (A)</p>
PHYSICAL	<ul style="list-style-type: none"> • Clinical breast exam (women age 50-69) (A) • Blood pressure measurement (B) • BMI measurement in obese adults (B) 	<p>Pediatrics: Repeated examinations of hips, eyes and hearing (especially in first year of life) (A) Serial heights, weights and head circumference (B) Visual acuity testing after age 2 (B)</p> <p>Adults > 65: Visual acuity (Snellen sight chart) (B) Hearing impairment (inquiry, whispered voice test, audioscope) (B)</p> <p>First degree relative with melanoma: Full body skin exam (B)</p>

Table 1. Periodic Health Exam (continued)

General Population	Special Population
TESTS <ul style="list-style-type: none"> Multiphase screening with the Hemoccult test (adults age >50 q1-2yrs) (A) Sigmoidoscopy (adults >50) (frequency not established) (B) Bone mineral density: if at risk (1 major or 2 minor criteria) Fasting lipid profile (C): <ul style="list-style-type: none"> Women age >50 or post-menopausal; earlier if at risk Men age >40; earlier if at risk (optimal frequency unknown, at least q5yrs) Fasting blood glucose: age >40 q3yrs (or sooner and more frequently if risk factors present) Syphilis screen if at risk (D) Men: PSA testing screening guidelines not established (I) Women: Mammography (women age 50-69) q1-2yrs (A) Pap smear annually (women age 18-69 if ever sexually active, start after sexual debut); q3yrs after 2 normal results (more frequently if concerns) 	Pediatrics: Routine hemoglobin for high risk infants (B) Blood lead screening of high risk infants (B) Diabetics: Urine dipstick (A) Fundoscopy (B) TB high risk groups: Mantoux skin testing (A) STI high risk groups: Voluntary HIV antibody screening (A) Gonorrhea screening (A) Chlamydia screening in women (B) FAP: Sigmoidoscopy and genetic testing (B) HNPCC: Colonoscopy (B)
THERAPY <ul style="list-style-type: none"> Folic acid supplementation to women of child-bearing age (A) Varicella vaccine for children age 1-12 and susceptible adolescents/adults (A) Rubella vaccine for all non-pregnant women of child-bearing age (B) Pharmacologic treatment of hypertension with dBp >90 mmHg (adults age 21-64, elderly specific subgroups) (A) Tetanus vaccine: routine booster q10yrs if had 1^o series (A) Pertussis vaccine: routine booster of acellular vaccine once during adulthood (can be given as dTap) 	Pediatrics: Routine immunizations (A) Hepatitis B immunization (A) Influenza high risk groups: Outreach strategies for vaccination (A) annual immunization (B), now recommended for all TB high risk groups: INH prophylaxis for household contacts or skin test converters (B) INH prophylaxis for high risk sub-groups (B) Immunocompetent/age ≥65/COPD: Pneumococcal vaccine (A)

Classification of recommendation in brackets. See sidebar on FM2.
Reference: Canadian Task Force on Preventative Health Care, 2005.

When Ordering Fasting Bloodwork

- Results are valid only if obtained with ≥12 hours of fasting.
- Remember, "fasting" means no food, no drinks (except small quantities of water), no gum, no smoking.
- Prescription medications are okay unless otherwise specified.

Guidelines Advisory Committee (GAC) Recommendations for Breast Cancer Screening

For women aged 40-69 years, there is fair evidence to recommend that routine teaching of breast self-examination (BSE) be excluded from the PHE. Research shows fair evidence of no benefit to BSE and good evidence of harm.

Health Promotion and Counselling

- health promotion is the most effective preventative strategy
- 40-70% of productive life lost annually is preventable
- there are several effective ways to promote healthy behavioural change, such as discussions appropriate to a patient's present stage of change

Motivational Strategies for Behavioural Change

Table 2. Motivational Strategies for Behavioural Change

Patient's Stage of Change	Physician's Aim	Physician's Plan
Pre-contemplation	Encourage patient to consider the possibility of change Assess readiness for change Increase patient's awareness of the problem and its risks	Raise issue in a sensitive manner Offer (not impose) a neutral exchange of information to avoid resistance
Contemplation	Understand patient's ambivalence and encourage change Build confidence and gain commitment to change	Offer opportunity to discuss pros and cons of change, using reflective listening
Preparation	Explore options and choose course most appropriate to patient Identify high-risk situations and develop strategies to prevent relapse Continue to strengthen confidence and commitment	Offer realistic options for change and opportunity to discuss inevitable difficulties
Action	Help patients design rewards for success Develop strategies to prevent relapse Support and reinforce convictions towards long-term change	Offer positive reinforcement and explore ways of coping with obstacles Encourage self-rewards to positively reinforce change
Maintenance	Help patient maintain motivation Review identifying high-risk situations and strategies for preventing relapse	Discuss progress and signs of impending relapse
Relapse	Help patient view relapse as a learning experience Provide support appropriate to present level of readiness post-relapse	Offer a non-judgmental discussion about circumstances surrounding relapse and how to avoid relapse in the future Reassess patient's readiness to change

Adapted from Hunt P. Motivating Change. *Nursing Standard* 2001; 16(2):45-52, 54-55.

Figure 1. Plate Layout

**Handy Serving Size Comparisons**

- 3 oz meat, fish, poultry → palm of hand
- 1 cup dairy (milk/yogurt) → size of fist
- Bread/grains → one slice, palm of hand
- ½ cup rice/pasta → one hand cupped
- 1 cup of fruit/vegetables → two cupped hands
- 1 oz cheese → full length of thumb
- 1 tsp oil/butter → tip of thumb
- Nuts/chips/snacks → palm covered

**Energy Content of Food**

- Carbohydrates 4 kcal/g
- Protein 4 kcal/g
- Fat 9 kcal/g
- Ethanol 7 kcal/g

**Calculating Total Daily Energy Expenditure (TDEE)**

- Roughly 35 kcal/kg/day
- Varies by age, weight, sex, and activity level
- Average 2000-2100 kcal/d for women, 2700-2900 kcal/d for men

**Canadian Cancer Society (CCS) Recommendations for Vitamin D Use**

- Based on CCS research on Vitamin D and the prevention of colorectal, breast and prostate cancer.
- In consultation with their healthcare provider, the Society is recommending that:
 - Adults living in Canada should consider taking Vitamin D supplementation of 1,000 international units (IU) a day during the fall and winter.
 - Adults at higher risk of having lower Vitamin D levels should consider taking Vitamin D supplementation of 1,000 IU/day all year round. This includes people: who are older, with dark skin, who don't go outside often, and who wear clothing that covers most of their skin.

Nutrition

General Population

- Canada's Food Guide is appropriate for individuals >2 years old
- counsel on variety, portion size, and plate layout (see Figure 1)

Table 3. Canada's Food Guide 2007 Recommendations for Adults

Food Group	Servings/day	Choose More Often
Grain products	6-8	Whole grain and enriched grain products
Vegetables and fruit	7-10	Dark green vegetables, orange vegetables and fruit
Milk products	2-3 Children 2-8 years: 2 Youth 9-18 years: 3-4 Pregnant/breastfeeding: 3-4	Lower-fat dairy products
Meat and alternatives	2-3	Lean meat, poultry, fish, peas, beans, lentils

Cardiovascular Disease Prevention**Table 4. Dietary Guidelines for Reducing Risk of Cardiovascular Disease in General Population**

Food Item	Recommendations	Effects
Fat	Fat intake <30% of total energy Saturated fat <7% of energy Trans fat <1% of energy Cholesterol <300 mg/d	Lower LDL
Omega-3 fatty acid rich foods	≥2 servings/wk of fish (esp. oily fish like salmon)	Decreased: sudden death, death from CAD Lower TG
Salt	<6 g/d (100 mmol or 2.3 g/d of sodium)	Lower BP
Alcohol	≤2 drinks/d for men ≤1 drink/d for women	Excess alcohol increases risk of hypertriglyceridemia, HTN

Table 5. Introduction to Vitamins and Minerals

Vitamin/Mineral	Dietary Source	Signs of Deficiency	Signs of Toxicity
Folate (vit B₉)	Green leafy vegetables, organ meats, dried yeast, dried beans, legumes, citrus, fortified grains	Macrocytic anemia, diarrhea, glossitis, lethargy, stomatitis	None known from foods; seizures
Cyanocobalamin (vit B₁₂)	Meats, organ meats, beef, pork, milk, cheese, fish	Megaloblastic anemia, glossitis, leukopenia, weakness, peripheral neuropathy (esp. foot drop)	None known from foods
Ascorbic acid (vit C)	Citrus fruits, tomatoes, potatoes, red berries, peppers	Scurvy, keratosis of hair follicles, impaired wound healing, anemia, depression, lethargy, bleeding	Osmotic diarrhea, N/V, oxalate kidney stones, interference with anticoagulation therapy
Vitamin A	Fish liver oils, egg yolk, dairy products, green leafy or orange/yellow vegetables and fruit	Dermatitis, night blindness, keratomalacia, xerophthalmia	N/V, headache, dizziness, deep bone pain, peeling skin, gingivitis, alopecia, hepatotoxicity
Vitamin D	Fish, fish liver oils, fortified milk, egg yolk, sunlight	Osteomalacia, muscle weakness, bone pain, hypophosphatemia, hypocalcemia	Excess bone and soft tissue calcification, kidney stones, hypercalcemia, anorexia, renal failure
Vitamin E	Polyunsaturated vegetable oils, nuts, eggs, wheat germ, whole grains	Rare hemolysis, anemia, neuronal axonopathy, myopathy	Prolonged clotting time, impaired neutrophil function
Vitamin K	Green leafy vegetables, liver, vegetable oils, intestinal flora	Bleeding, purpura, bruising, prolonged clotting time	Jaundice
Calcium	Dairy products, dark, green and leafy vegetables, fortified soy, fortified orange juice	Tetany, arrhythmias, congestive heart failure, altered nerve conduction, osteomalacia	Metastatic calcification, weakness, renal failure, psychosis

Table 5. Introduction to Vitamins and Minerals (continued)

Vitamin/Mineral	Dietary Source	Signs of Deficiency	Signs of Toxicity
Magnesium	Soy, clams, wheat germ, almonds, dairy products, green leaves, nuts, cereal grains, seafood	Weakness, convulsions, neuromuscular irritability and dysfunction, failure to thrive	Hypotension, cardiac disturbances, respiratory failure
Potassium	Meat, milk, bananas, prunes, raisins, orange, grapefruit, potatoes, legumes	Polyuria, impaired muscle contraction, ECG changes (prolonged QT interval, prominent U-waves), peritoneal distention, dyspnea, paralysis, cardiac disturbances	Mental confusion, hypotension, weakness, ECG changes (flattened P-waves, peaked T-waves), paralysis, cardiac disturbances
Iron	Meat, fish, poultry, organ meats, eggs, prunes, peas, beans, lentils, soy, raisins, fortified grain products	Glossitis, fatigue, tachycardia, microcytic hypochromic anemia, koilonychia, enteropathy	Nutritional hemosiderosis, organ damage

Table 6. Macronutrient Distribution Ranges

Age (years)	Macronutrient as % of Daily Calories		
	Protein	Fat	Carbohydrate
1 to 3	5 - 20	30 - 40	45 - 65
4 to 18	10 - 30	25 - 35	45 - 65
19 and older	10 - 35	20 - 35	45 - 65

Adapted from Dietary Reference Intakes Tables, Health Canada. http://www.hc-sc.gc.ca/fn-an/nutrition/reference/table/index_e.html

Obesity

- body mass index (BMI) = weight (kg)/height (m)² = weight (lbs)/height (inch)² x 703
- waist circumference (WC)
 - should be measured in all adults to assess obesity-related health risks
 - specific cutoff points exist for different ethnic backgrounds (as recommended by the 2006 Canadian Clinical Practice Guidelines on obesity)
 - measurement of waist-hip ratio has no advantage over waist circumference alone

Table 7. Classification of Weight by BMI, Waist Circumference, and Associated Disease Risks in Adults

	BMI (kg/m ²)	Obesity Class	Men ≤102 cm (40 in) Women ≤88 cm (35 in)	Men >102 cm (40 in) Women >88 cm (35 in)
Underweight	<18.5		—	—
Normal	18.5-24.9		—	—
Overweight	25.0-29.9		Increased	High
Obesity	30.0-34.9	I	High	Very High
	35.0-39.9	II	Very High	Very High
Extreme Obesity	40.0 +	III	Extremely High	Extremely High

From: Classification of Overweight and Obesity by BMI, Waist Circumference, and Associated Disease Risks, National Institute of Health, National Heart Lung and Blood Institute, Obesity Education Initiative, http://www.nhlbi.nih.gov/health/public/heart/obesity/lose_wt/bmi_dis.htm

Epidemiology

- 16% (4 million) of people ≥18 years old are obese, 32% (8 million) are overweight in Canada, according to StatsCan (2007)
- obesity rate in people of aboriginal origin is 1.6 times higher than the national average
- proportion of children aged 6-11 who are overweight has more than doubled in the last 25 years; percentage of overweight adolescents has tripled
- overweight and obesity rates in children are directly proportional to screen time (see *Exercise*, FM7)
- only 10-15% of population consume <30% fat daily
- obese persons generally consume more energy-dense food which tends to be highly processed, micronutrient poor, and high in fats, sugars, or starch

Burning Fat

3500 kcal of energy are produced for every pound of human fat burned during activity.

Losing Weight

- Aim for caloric intake 500-1000 kcal/d less than total daily energy expenditure (TDEE)
- Results in 1-2 lb (0.5-1 kg) weight loss per week
- Achieved by combination of increased activity and/or decreased caloric intake

Low BMI is Associated with:

- Osteoporosis
- Eating disorders
- Under-nutrition
- Pregnancy complications

Adverse Medical Consequences of Obesity

- Type 2 DM
- CAD
- Stroke
- HTN
- Gallbladder disease
- Non-alcoholic steatohepatitis
- Complications of pregnancy
- Dyslipidemia
- Osteoarthritis
- Sleep apnea
- Certain cancers
- CHF
- Low back pain
- Increased total mortality

"The Latest Evidence on Fad Diets..."
Comparison of the Atkins, Ornish, Weight Watchers, and Zone diets for Weight Loss and Heart Disease Risk Reduction
JAMA 2005; 293(1):43-53
Purpose: To assess the effectiveness and adherence rates of four popular diets for weight loss and reduction of cardiac risk factors.
Study Characteristics: Single center RCT at academic medical center in Boston, MA; 160 participants were randomized to either Atkins (carbohydrate restriction), Zone (macronutrient balanced and low glycemic load), Weight Watchers (low calorie/portion size), or Ornish (fat restriction) diet groups for a period of 18 months.
Participants: Adults aged 22 to 72 years with known HTN, dyslipidemia, or fasting hyperglycemia.
Results: Assuming that participants who discontinued the study remained at baseline, the mean weight loss at 1 year (and self selected dietary adherence rates per self report) were 2.1 kg for Atkins (53% of participants completed, $P=0.009$), 3.2 kg for the Zone (65% of participants completed, $P=0.002$), 3.0 kg for Weight Watchers (65% completed, $P<0.001$), 3.3 kg for Ornish (50% completed, $P=0.007$). Each diet significantly reduced the LDL/HDL ratio by ~10% ($P<0.05$), with no significant effects on blood pressure or glucose. Amount of weight loss was associated with adherence level ($r = 0.60$; $P<0.001$) but not with diet type ($r = 0.07$; $P = 0.40$). Weight loss for each diet was significantly associated with reduction in levels of total/HDL cholesterol ($r=0.36$), C-reactive protein ($r=0.37$), and insulin ($r=0.39$), with no significant difference between diets.
Conclusion: Each popular diet was associated with modest weight loss and reduction of several cardiac risk factors. Adherence level, and not diet type, was the most important predictor of weight loss and cardiac risk factor reduction.

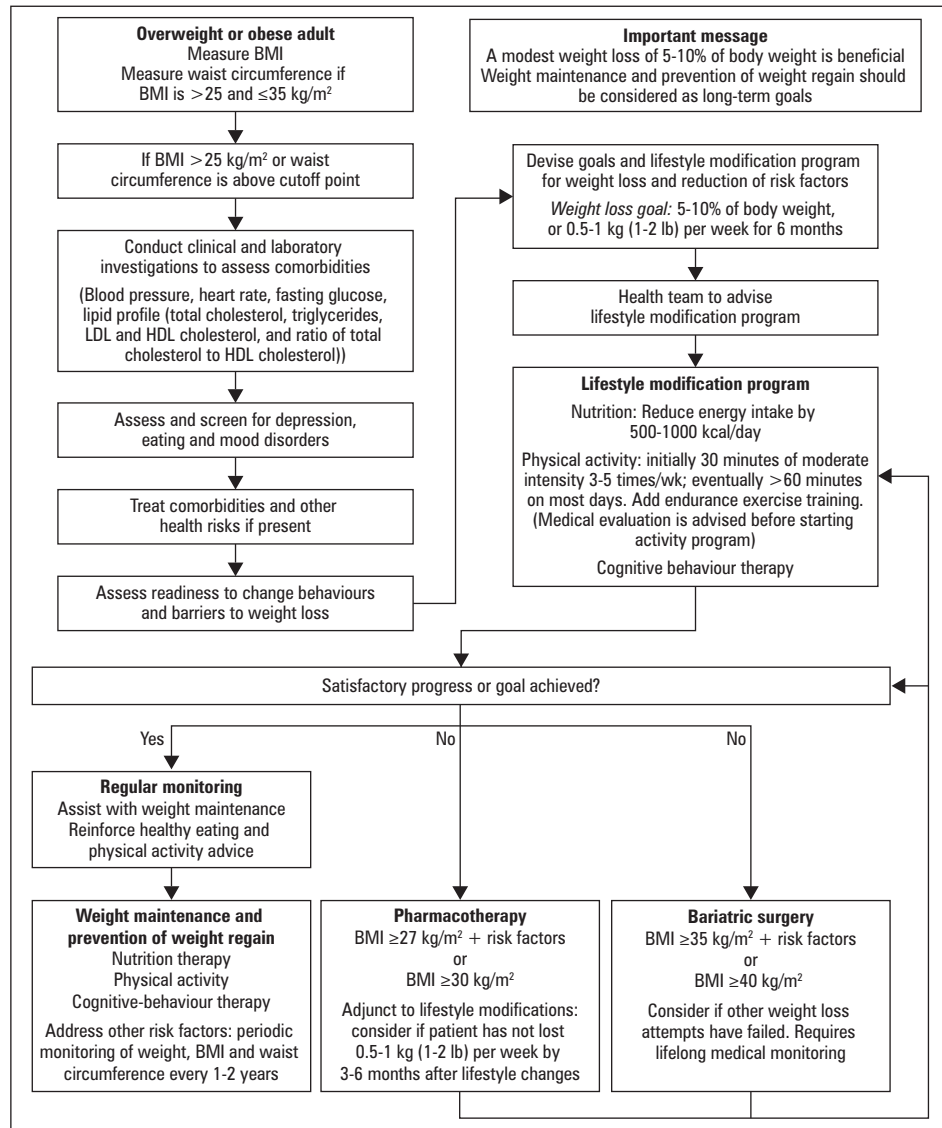

Figure 2. 2006 Canadian Clinical Practice Guidelines on the Management and Prevention of Obesity in Adults and Children (summary)
 Adapted from *CMAJ* 2007; 176:S1-S13.

Hyperlipidemia Signs

1. Atheromata – plaques in blood vessel walls
2. Xanthoma – plaques or nodules composed of lipid-laden histiocytes in the skin (esp. the eyelids)
3. Tendinous xanthoma – lipid deposit in tendon (esp. Achilles)
4. Corneal arcus (arcus senilis) – lipid deposit in cornea

LDL cannot be calculated when TG ≥4.5 mmol/L.

Clinical Definition of Metabolic Syndrome

- Central obesity
 - Men – waist circumference ≥94 cm
 - Women – waist circumference ≥80 cm
- plus any TWO of the following four factors:

Risk Factor	Defining Level
TG level	≥1.7 mmol/L (150 mg/dL)
HDL-C level:	
Men	<1.0 mmol/L (40 mg/dL)
Women	<1.3 mmol/L (50 mg/dL)
Blood pressure	≥130/85 mmHg
Fasting glucose level	≥5.6 mmol/L (100 mg/dL)

Dyslipidemia

- see [Endocrinology](#), E2
- defined as abnormal elevation of plasma cholesterol or triglyceride levels
- increased risk associated with obesity, DM, alcohol use

Assessment

- measure fasting serum TC, LDL-C, HDL-C, and TG
- screen with full fasting lipid profile in males over age 40, females over age 50 or who are menopausal, or any adults with additional CAD risk factors q1-3yrs
- assess for presence of other CAD risk factors
- screen for secondary causes: hypothyroidism, chronic kidney disease, DM, nephrotic syndrome, liver disease
- risk category
 - estimate using the model for 10-year CAD risk developed from the Framingham data
 - primary target of therapy is LDL-C levels; the alternate primary target is ApoB
 - optional secondary targets once LDL-C/apoB is at target include apoB:apoAI ratio, TC:HDL-C ratio, hs-CRP, non-HDL-C and serum TG levels
- emerging risk factors (from Framingham group)
 - lipoprotein a
 - metabolic syndrome
 - genetic risk
 - hormone replacement therapy
 - infectious agents

Table 8. Target Lipid Values for Primary Prevention of CAD in mmol/L (mg/dL)

Risk Category	Initiate Treatment if:	Primary Targets	
		LDL-C	Alternate
High (10-yr risk of CAD $\geq 20\%$, or history of DM or any atherosclerotic disease)	Consider treatment in all patients	$< 2 \text{ mmol/L}$ or $\geq 50\%$ decrease in LDL-C	$\text{apoB} < 0.80 \text{ g/L}$
Moderate (10-yr risk 11-19%)	LDL-C $> 3.5 \text{ mmol/L}$ TC/HDL-C > 5.0 Hs-CRP $> 2 \text{ mg/L}$ Men > 50 years Women > 60 years	$< 2 \text{ mmol/L}$ or $\geq 50\%$ decrease in LDL-C	$\text{apoB} < 0.80 \text{ g/L}$
Low (10-yr risk $\leq 10\%$)	LDL-C $\geq 5.0 \text{ mmol/L}$	$\geq 50\%$ decrease in LDL-C	

Reference: J Genest, R McPherson, J Frohlich, et al. 2009 Canadian Cardiovascular Society/Canadian guidelines for the diagnosis and treatment of dyslipidemia and prevention of cardiovascular disease in the adult – 2009 recommendations. *Can J Cardiol* 2009; 25(10):567-579.

Management

- intensity and type of treatment is guided by “risk category” assigned
- 1. health behaviours (can decrease LDL-C by up to 10%)
 - smoking cessation – probably the most important for preventing CAD
 - dietary modification – reduce saturated fats, refined sugars, alcohol; increase fruits, vegetables and fibres
 - physical activity – 30-60 min of moderate to vigorous activity on most days
 - employ consistent lifestyle modifications for at least 3 months before considering drug therapy; high risk patient should start treatment immediately with concurrent health behaviour interventions
- 2. pharmacologic therapy (can decrease LDL-C by up to 40%)
 - for a comparison of dyslipidemia medications, see Endocrinology, E5
 - statins (HMG-CoA reductase inhibitors)
 - currently recommended as 1st line monotherapy following unsuccessful lifestyle modifications
 - risks: myopathy and hepatotoxicity – must follow LFTs every 6 months
 - other agents: bile acid sequestrants, nicotinic acid, fibrates, psyllium, cholesterol absorption inhibitors (e.g. ezetimibe)
- after initiating drug therapy
 - fasting lipids should be measured after 6 weeks, and at 3 months
 - if adequate response is achieved, evaluate fasting lipids q4-6months
 - monitor ALT, AST, CK at baseline then 6 weeks later for signs of transaminitis or myositis; tolerate rise in CK within 10 times upper limit of normal, or creatinine of $\leq 25\%$; repeat ALT, AST and CK with lipid bloodwork
- isolated hypertriglyceridemia
 - normal HDL-C and TC, elevated TG
 - mild $\geq 2.2 \text{ mmol/L}$ ($\geq 200 \text{ mg/dL}$); marked $\geq 5.6 \text{ mmol/L}$ ($\geq 500 \text{ mg/dL}$)
 - principal therapy is lifestyle modifications
 - weight loss, exercise, avoidance of smoking and alcohol, effective blood glucose control in diabetics, increased omega-3 fatty acid intake
 - drug therapy
 - nicotinic acid
 - fibrates

Exercise

Epidemiology

- 25% of population exercises regularly, 50% occasionally, 25% sedentary
- screen time (time spent watching TV/movies, playing video games, or using the computer) has been increasing steadily in the last several years, while time spent being physically active has been decreasing
- excessive screen time can lead to obesity, encourage violent and antisocial behaviours, and foster attention deficit difficulties
- current recommendation from international pediatric societies is that children (> 2 years old) should limit their screen time to less than 2 hours/day

Model for Calculating the 10-year Risk of CAD in a Patient Without Diabetes Mellitus or Clinically Evident Cardiovascular Disease*, Using Framingham Data

STEP 1: DETERMINE RISK POINTS

Risk Factor	Risk Points		Risk Factor	Risk Points	
	Men	Women		Men	Women
Age, year					
30-34	-1	-9	55-59	4	7
35-39	0	-4	60-64	5	8
40-44	1	0	65-69	6	8
45-49	2	3	70-74	7	8
50-54	3	6			
Total cholesterol level, mmol/L					
< 4.14	-3	-2	6.22-7.24	2	2
4.15-5.17	0	0	≥ 7.25	3	3
5.18-6.21	1	1			
HDL-C level, mmol/L					
< 0.90	2	5	1.30-1.55	0	0
0.91-1.16	1	2	≥ 1.56	-2	-3
1.17-1.29	0	1			
Systolic blood pressure, mmHg					
< 120	0	-3	140-159	2	2
120-129	0	0	≥ 160	3	3
130-139	1	1			
Smoker					
No	0	0	Yes	2	2

STEP 2: CALCULATE RISK**

Total Risk Points	10-year Risk, %		Total Risk Points	10-year Risk, %	
	Men	Women		Men	Women
1	3	2	10	25	10
2	4	3	11	31	11
3	5	3	12	37	13
4	7	4	13	45	15
5	8	4	14	≥ 53	18
6	10	5	15		20
7	13	6	16		24
8	16	7	17		> 27
9	20	8			

*For example, a 55-year-old man who has a total cholesterol level of 5.43 mmol/L, an HDL-C level of 1.23 mmol/L, a systolic blood pressure of 148 mmHg and who smokes would have a total risk score of 9. His 10-year risk for CAD would be 20%, the risk for the average person of his age in the study population is 16%.

**Risk of CAD outcomes including angina pectoris, unstable angina, nonfatal myocardial infarction and coronary death over subsequent 10 years for a Framingham Study participant with that specific risk score.

Reference: Recommendations for the management of dyslipidemia and the prevention of cardiovascular disease: Summary of the 2003 update. *CMAJ* 2003; 169(1):921-924.

Comparative Tolerability of HMG-CoA Reductase Inhibitors

Drug Safety 2000; 23(3):197-213

Study: Review

Results: 1. There is no evidence to support that statin therapy leads to increased incidence of cataract formation. 2. Statin therapy does not lead to statistically significant disturbance in sleep or cognition compared to placebo. 3. The incidence of hepatotoxicity and elevated transaminases depends on statin dose. In general, all statins are similar in their rates of liver toxicity. 4. Statins metabolized solely by CYP3A4 (e.g. lovastatin, simvastatin, atorvastatin, cerivastatin) are more likely to result in hepatotoxicity or rhabdomyolysis if used in combination with a CYP3A4 inhibiting drug (e.g. ketoconazole, grapefruit juice, erythromycin).

Incidence of Hospitalized Rhabdomyolysis in Patients Treated with Lipid-Lowering Drugs

JAMA 2004; 292(21):2585-2590

Study: Retrospective cohort study.

Patients: 252460 patients treated with lipid-lowering agents.

Main outcome: Rhabdomyolysis requiring hospitalization.

Results: Of 252460 patients, 24 cases of rhabdomyolysis requiring hospitalization occurred. Incidence rates per 10000 person-years with 95% CI for each statin monotherapy are:

Atorvastatin 0.54 (0.22-1.12)

Cerivastatin 5.34 (1.46-13.68)

Pravastatin 0 (0-1.11)

Simvastatin 0.49 (0.06-1.76)

Fenofibrate 0 (0-14.58)

Gemfibrozil 3.70 (0.76-10.82)

Incidence of rhabdomyolysis increased to 5.98 (95% CI, 0.72-216.0) if atorvastatin, pravastatin or simvastatin was used with a fibrate, and up to 1035 (95% CI, 389-2117) if cerivastatin was combined with a fibrate.

Use with caution when prescribing combined statin and fibrate therapy as there has been recent concerns regarding the safety of certain combinations.

Management

- assess current level of fitness, motivation and access to exercise
- encourage warm up and cool down periods to allow transition between rest and activity and to avoid injuries
- exercise with caution for patients with CAD, diabetes (risk of hypoglycemia), exercise-induced asthma
- balanced exercise program incorporating all types of exercise
 1. aerobic (endurance) exercise for 15-60 min, 4-7 times/wk
 - ♦ improves cardiac function, lowers BP, increases HDL, increases insulin sensitivity
 - ♦ target HR: 60-80% of maximum HR
 - ♦ maximum HR=220-age
 2. weight-bearing (isometric) exercise 10-20 min, 2-4 times/wk
 - ♦ builds muscle strength, improves bone density, improves posture
 3. stretching routine 10-12 min, 4-7 times/wk
 - ♦ prevents cramps, stiffness, injuries, back problems
- other benefits of exercise
 - improves feeling of well-being, libido, quality of sleep, self-esteem
 - decreases depression and anxiety
 - weight control

Smoking Cessation

Physician Advice for Smoking Cessation

Cochrane Database of Systematic Reviews 2008; Issue 2

This systematic review of 17 trials compared brief advice by the physician versus no advice.

Reviewers' conclusions: Simple advice can increase cessation rates by 1 to 3%. More intensive advice and providing follow-up support may further increase the quit rates.

The 5 As for Patients Willing to Quit

Ask if patient smokes
Advise patient to quit
Assess willingness to quit
Assist in quit attempt
Arrange follow-up

Assist Patient in Developing Quit Plan

STAR
Set quit date
Tell family and friends (for support)
Anticipate challenges (e.g. withdrawal)
Remove tobacco products (e.g. ashtrays/lighters)

Epidemiology

- smoking is the single most preventable cause of premature illness and death
- 70% of smokers see a physician each year
- 2008 Canadian data from the Canadian Tobacco Use Monitoring Survey (CTUMS) on population age 15 or older
 - 18% are current smokers (lowest since 1965)
 - highest prevalence in age group 20-24 (28%)
 - 15% of youth aged 15-19 smoke (decreased from 25% in 2000): more males smoke than females (18% vs. 13%; 23% vs. 27% in 2000), cigarettes consumed per day also decreasing
 - in 2006, smoking rate decreased significantly among youth aged 15-19, from 18% down to 15%

Management

- **general approach**
 - identify tobacco users, elicit smoking habits, previous quit attempts and results
 - every smoker should be offered treatment
 - make patient aware of withdrawal symptoms
 - ♦ low mood, insomnia, irritability, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite
 - ≥4 counselling sessions >10 min each with 6-12 month follow-up yield better results
 - 14% abstinent with counselling vs. 10% without counselling (OR 1.55)
 - approach depends on patient's stage of change (see *Motivational Strategies for Behavioural Change*, FM3)
- **willing to quit**
 - follow the 5 As (see sidebar)
 - provision of social support, community resources
 - pregnant patients: advise to quit first without pharmacotherapy; use pharmacotherapy only if benefits > risks; consult Motherisk
 - Nicotine Replacement Therapy (NRT)
 - ♦ 19.7% abstinent at 12 months with NRT vs. 11.5% for placebo (OR 1.66)
 - ♦ no difference in achieving abstinence for different forms of NRT
 - ♦ reduces cravings and withdrawal symptoms without other harmful substances that are contained in cigarettes
 - ♦ use with caution: immediate post-MI, serious/worsening angina, serious arrhythmia
 - Bupropion SR (Zyban®)
 - ♦ 21% abstinent at 12 months vs. 8% for placebo (OR 2.73)
 - Varenicline (Champix®)
 - ♦ partial nicotinic receptor agonist (to reduce cravings) and partial competitive nicotinic receptor antagonist (to reduce the response to smoked nicotine)
 - ♦ more effective than bupropion

Table 9. Types of Nicotine Replacement Therapy

Type	Dosage	Comment	Side Effects
Nicotine Gum (OTC)	2 mg if <25 cig/d 4 mg if >25 cig/d 1 piece q1-2h for 1-3 mos (max. 24 pieces/d)	Chew until "peppery" taste then "park" between gum and cheek to facilitate absorption Continue to chew-park intermittently for 30 min	Mouth soreness Hiccups Dyspepsia Jaw ache Most SE's are transient
Nicotine Patch (OTC)	Use for 8 weeks 21 mg/d x 4 weeks 14 mg/d x 2 weeks 7 mg/d x 2 weeks	Start with lower dose if <10 cig/d Change patch q24h and alternate sides	Skin irritation Insomnia Palpitations Anxiety
Nicotine Inhaler (OTC)	6-16 cartridges/day for up to 12 weeks	Nicotine inhaled through mouth, absorbed in mouth and throat but not in lungs	Local irritation Coughing
Nicotine Nasal Spray (Rx)		Not available in Canada	

Nicotine Replacement Therapy for Smoking Cessation

Cochrane Database of Systematic Reviews 2008; Issue 1

This systematic review of 132 randomized trials compared NRT to placebo or no treatment or compared different NRT doses.

Reviewers' conclusions: All commercially available forms of NRT (gum, transdermal patch, nasal spray, inhaler and sublingual tablets/lozenges) are effective as part of a strategy to promote smoking cessation. They increase the rate of quitting by 50 to 70% regardless of setting and independent on the level of additional support provided to the smoker. Compared to a single form of NRT, combining a nicotine patch with a rapid delivery form of NRT may be more effective.

Table 10. Bupropion as Treatment for Smoking Cessation

Mechanism	Dosage	Prescribing*	Contraindications
Inhibits re-uptake of dopamine and/or norepinephrine	1. 150 mg qAM x 3 days 2. Then 150 mg bid x 7-12 wks 3. For maintenance consider 150 mg bid for up to 6 months	1. Decide on a quit date 2. Continue to smoke for first 1-2 wks of treatment and then completely stop (therapeutic levels reached in 1 wk)	Seizure disorder Eating disorder MAOI use in past 14 days Simultaneous use of bupropion (Wellbutrin®) for depression

*May be used in combination with nicotine replacement therapy

Antidepressants for Smoking Cessation

Cochrane Database of Systematic Reviews 2007; Issue 1

This systematic review of 66 randomized trials compared antidepressant medication to placebo or alternative pharmacotherapy for smoking cessation and where follow-up was longer than 6 months.

Reviewers' conclusions: The antidepressants bupropion and nortriptyline can aid smoking cessation and have a similar efficacy to NRT. Compared to bupropion, varenicline showed higher quit rates. Selective serotonin reuptake inhibitors (e.g. fluoxetine) or venlafaxine did not have a significant effect.

Table 11. Varenicline as Treatment for Smoking Cessation

Mechanism	Dosage	Prescribing*	Contraindications
Partial nicotinic receptor agonist, and partial competitive antagonist nicotinic receptor	1. 0.5 mg qAM x 3 days 2. Then 0.5 mg bid x 4 days 3. Continue 1 mg BID x 12 weeks plus ± additional 12 weeks as maintenance	Begin treatment 1 week before quit date, then stop smoking as planned	Caution with pre-existing psychiatric condition

*May be used in combination with nicotine replacement therapy

• unwilling to quit

- motivational intervention (5 Rs) (see sidebar):

1. Risks of smoking

- ♦ short-term: SOB, asthma exacerbation, impotence, infertility, pregnancy complications, heartburn, URTI
- ♦ long-term: MI, stroke, COPD, lung CA, other cancers
- ♦ environmental: higher risk in spouse/children for lung CA, SIDS, asthma, respiratory infections

2. Rewards: benefits

- ♦ improved health, save money, food tastes better, good example to children

3. Road blocks: obstacles

- ♦ fear of withdrawal, weight gain, failure, lack of support

4. Repetition

- ♦ reassure unsuccessful patients that most people try many times before successfully quitting (average number of attempts before success is 7)

• recent quitter

- highest relapse rate within 3 months of quitting

- ♦ minimal practice: congratulate on success, encourage ongoing abstinence, review benefits, problems
- ♦ prescriptive interventions: address problems of weight gain, negative mood, withdrawal, lack of support

**The 2-3 Pattern of Smoking Cessation**

- Onset of withdrawal is 2-3 hours after last cigarette
- Peak withdrawal is at 2-3 days
- Expect improvement of withdrawal symptoms at 2-3 weeks
- Resolution of withdrawal at 2-3 months
- Highest relapse rate within 2-3 months

**The 5 Rs for Patients Unwilling to Quit**

Relevance to patient (health concerns, family/social situations)

Risks of smoking

Rewards of quitting

Roadblocks to quitting

Repetition of motivational intervention at each visit

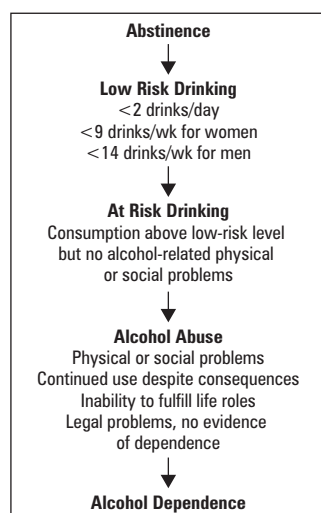

Figure 3. Continuum of Alcohol Use

**Standard Drink Equivalents**

One standard drink = 14 g of pure alcohol

- Beer (5% alcohol) = 12 oz
- Wine (12-17% alcohol) = 5 oz
- Fortified wine = 3 oz
- Hard liquor (80 proof) = 1.5 oz

**CAGE Questionnaire**

- C** Have you ever felt the need to **CUT** down on your drinking?
A Have you ever felt **ANNOYED** at criticism of your drinking?
G Have you ever felt **GUILTY** about your drinking?
E Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover?
(EYE OPENER)

≥2 for men or ≥1 for women suggests possibility of problem drinking (sensitivity 85%, specificity 89%)

**Alcohol Metabolized per Hour**

- Alcohol metabolism is constant (zero-order kinetics) regardless of blood alcohol level (BAL)
- Average metabolism ranges between 13-25 mg/dL blood/hour or 100-200 mg/kg/hour
- Equivalent to metabolizing 0.5-1 standard drink per hour or BAL decrease of 0.01% per hour
- Metabolism more rapid in chronic alcoholics

**Some Adverse Medical Consequences of Problem Drinking**

- GI: gastritis, dyspepsia, pancreatitis, liver disease, bleeds, diarrhea, oral/esophageal cancer
- Cardiac: hypertension, alcoholic cardiomyopathy
- Neurologic: Wernicke-Korsakoff syndrome, peripheral neuropathy
- Hematologic: anemia, coagulopathies
- Other: trauma, insomnia, family violence, anxiety/depression, social/family dysfunction, sexual dysfunction, fetal damage

Alcohol

- see Psychiatry, PS20

Definition

- diagnostic categories occur along a continuum (see Figure 3)

Epidemiology

- 10-15% of patients in family practice are problem drinkers
- 20-50% of hospital admissions, 10% of premature deaths, 30% of suicides, and 50% of fatal traffic accidents in Canada are alcohol-related
- more likely to miss diagnosis in women, elderly, patients with high socioeconomic status

Assessment

- screen for alcohol dependence with CAGE questionnaire (see sidebar)
 - if CAGE positive, explore with further questions for alcohol abuse
- assess drinking profile
 - setting, time, place, occasion, with whom
 - impact on: family, work, social
 - quantity-frequency history
 - ♦ how many drinks per day?
 - ♦ how many days per week?
 - ♦ maximum number of drinks on any one day in the past month?
- if identified positive for alcohol problem
 - screen for other drug use
 - identify medical/psychiatric complications
 - ask about drinking and driving
 - ask about past recovery attempts and current readiness for change

Investigations

- GGT and MCV for baseline and follow-up monitoring
- AST, ALT (usually AST:ALT approaches 2:1 in an alcoholic)
- CBC (anemia, thrombocytopenia), INR (decreased clotting factors production by liver)

Management

- intervention should be consistent with patient's motivation for change
- regular follow-up is crucial
- 10% of patients in alcohol withdrawal will have seizures or delirium tremens
- Alcoholics Anonymous/12-step program
 - outpatient/day programs for those with chronic, resistant problems
 - family treatment (Al-Anon, Alateen, screen for spouse/child abuse)
- in-patient program if
 - dangerous or highly unstable home environment
 - severe medical/psychiatric problem
 - addiction to drug that may require in-patient detoxification
 - refractory to other treatment programs
- pharmacologic
 - diazepam for withdrawal
 - disulfiram (Antabuse®): impairs metabolism of alcohol by blocking conversion of acetaldehyde to acetic acid, leading to flushing, headache, nausea/vomiting, hypotension if alcohol is ingested
 - naltrexone: competitive opioid antagonist that reduces cravings and pleasurable effects of drinking
 - ♦ may trigger withdrawal in opioid-dependent patients

Prognosis

- relapse is common and should not be viewed as failure
- monitor regularly for signs of relapse
- 25-30% of abusers exhibit spontaneous improvement over 1 year
- 60-70% of individuals with jobs and families have an improved quality of life 1 year post-treatment

Common Presenting Problems

Abdominal Pain

- see Gastroenterology, G2 and General Surgery, GS4

Epidemiology

- 20% of individuals have experienced abdominal pain within the last 6-12 months
- 90% resolve in 2-3 weeks
- only 10% are referred to specialists, <10% admitted to hospital

Etiology

- most common diagnosis is “nonspecific abdominal pain,” which has no identifiable cause and is usually self-limited
- GI disorders (e.g. PUD, pancreatitis, IBD, appendicitis, gastroenteritis, IBS, diverticular disease, biliary tract disease)
- urinary tract disorders (e.g. UTI, renal calculi)
- gynecological disorders (e.g. PID, ectopic pregnancy, endometriosis)
- cardiovascular disorders (e.g. CAD, AAA, ischemic bowel)
- other: toxic ingestion, foreign body, psychogenic

Pathophysiology

- type of pain
 - somatic pain – sharp, localized pain
 - visceral pain – dull, generalized pain
- location of pain
 - epigastric (foregut) – distal esophagus, stomach, proximal duodenum, biliary tree, pancreas, liver
 - periumbilical (midgut) – distal duodenum to proximal 2/3 of transverse colon
 - hypogastric (hindgut) – distal 1/3 of transverse colon to rectosigmoid region

Investigations

- guided by findings on history and physical
- possible bloodwork: CBC, electrolytes, BUN, Cr, amylase, lipase, AST, ALT, ALP, bilirubin, glucose, INR/PTT, tox screen, beta-hCG
- imaging
 - abdominal x-ray (gas pattern, free air)
 - ultrasound (gallbladder disease, gynecological problems)
 - CT scan (AAA, appendicitis)
- other tests
 - urinalysis
 - endoscopy (for peptic ulcers, gastritis, tumours, etc.)
 - *H. pylori* testing (urea breath test, serology)

In patient >50 years old, keep a high index of suspicion for AAA – its presentation may mimic renal colic or diverticulitis.

If pain precedes nausea/vomiting, cause of abdominal pain is more likely to be surgical.

Allergic Rhinitis

- see Otolaryngology, OT23

Definition

- inflammation of the nasal mucosa that is triggered by an allergic reaction
- classification:
 - seasonal
 - ♦ symptoms during a specific time of the year
 - ♦ common allergens: trees, grass and weed pollens, airborne moulds
 - perennial
 - ♦ symptoms throughout the year with variation in severity
 - ♦ common allergens: dust mites, animal dander, moulds

Etiology

- increased IgE levels to certain allergens → excessive degranulation of mast cells → release of inflammatory mediators (e.g. histamine) and cytokines → local inflammatory reaction

**Differential Diagnosis**

- Acute viral infection
- Vasomotor rhinitis
- Deviated septum
- Nasal polyps
- Acute/chronic sinusitis
- Drug-induced rhinitis
- Pregnancy

Rhinitis medicamentosa – Rebound nasal congestion. Occurs with prolonged use (>5-7 days) of vasoconstrictive medications. Patient may become dependent, requiring more frequent dosing to achieve the same decongestant effect.

Epidemiology

- affects approximately 40% of children and 20-30% of adults
- prevalence has increased in developed countries, particularly in the past two decades
- associated with asthma, sinusitis, and otitis media

Assessment

- identify allergens
- take an environmental/occupational history
- ask about related conditions (e.g. atopic dermatitis, asthma, sinusitis, and family history)

Management

- conservative
 - minimize exposure to allergens
 - ♦ most important aspect of management, often sufficient (may take months)
 - maintain hygiene, saline nasal rinses
- pharmacologic agents
 - oral antihistamines – first line therapy for mild symptoms
 - ♦ e.g. cetirizine (Reactine®), fexofenadine (Allegra®), loratadine (Claritin®)
 - intranasal corticosteroids for moderate/severe or persistent symptoms (>1 month of consistent use to see results)
 - intranasal decongestants (use must be limited to <5 days to avoid rhinitis medicamentosa)
- allergy skin testing
 - for patients with chronic rhinitis
 - symptoms not controlled by allergen avoidance, pharmacological therapy
 - may identify allergens to include in immunotherapy treatment
- immunotherapy (allergy shots)
 - reserved for severe cases unresponsive to pharmacologic agents
 - consists of periodic (usually weekly) subcutaneous injections of custom prepared solutions of one or more antigens to which the patient is allergic

Amenorrhea

- see Gynecology, G12

Definition and Etiology

- classified as primary or secondary
 - primary
 - ♦ absence of menstruation by age 14 in women without secondary sexual characteristics, or absence of menstruation by age 16 in women with secondary sexual characteristics
 - ♦ causes: Turner's syndrome, constitutional delay of growth and puberty, Kallmann syndrome, androgen insensitivity syndrome, Mullerian agenesis, imperforate hymen, transverse vaginal septum, also include differential of secondary amenorrhea
 - secondary
 - ♦ absence of menstruation for 3 months in women with previously normal menstruation, or absence of menstruation for 9 months in women with previous oligomenorrhea
 - ♦ causes: pregnancy, hypothyroidism, hyperprolactinemia, medications, premature ovarian failure, anorexia or bulimia nervosa, CNS tumour, chronic illness, PCOS

Assessment

- history
 - menarche and menstrual history, sexual activity, exercise, weight loss, current or previous chronic illness, prescription/illicit drug use, previous CNS chemo or radiation, previous pelvic radiation, psychosocial stressors
 - family history of genetic defects, infertility, menarche and menstrual history, pubertal history
- physical
 - growth chart, BMI, Tanner staging, dysmorphic features (e.g. webbed neck, short stature), signs of Cushing's disease, thyroid exam, hirsutism or acne, pubic hair pattern, imperforate hymen, absent uterus

Investigations

- based on clinical picture
- consider beta-hCG, prolactin, TSH, progesterone challenge test, FSH and LH levels, head MRI, karyotype

Anxiety

- see Psychiatry, PS12

Epidemiology

- 25-30% of patients in primary care settings have psychiatric disorders
- many are undiagnosed or untreated; hence the need for good screening
- high rate of coexistence of anxiety disorders and depression

Screening

- screening questions
 - Do you tend to be an anxious or nervous person?
 - Have you felt unusually worried about things recently?
 - Has this worrying affected your life? How?
- if positive response, follow up with symptom-specific questions (see Figure 4)

Assessment

- associated symptoms
- risk factors
 - family history of anxiety or depression, past history of anxiety, stressful life event, social isolation, gender (women), co-morbid psychiatric diagnosis
- assess substance abuse, co-morbid depression, suicidal ideations/self-harm
- to differentiate anxiety disorders, consider symptoms and their duration (see Figure 4)

Differential Diagnosis (see Figure 4)

- Panic disorder
- GAD
- PTSD
- OCD
- Social phobia
- Specific phobia
- Separation anxiety (children)
- Other: GMC, mood disorder, psychotic disorder

Rule Out

- Cardiac (post MI, arrhythmias)
- Endocrine (hyperthyroidism, diabetes, pheochromocytoma)
- Respiratory (asthma, COPD)
- Somatoform disorders
- Psychotic disorders
- Mood disorders (depression, bipolar)
- Personality disorder (OCPD)
- Drugs (amphetamines, thyroid preparations, caffeine, OTC for colds/decongestants, alcohol/benzodiazepine withdrawal)

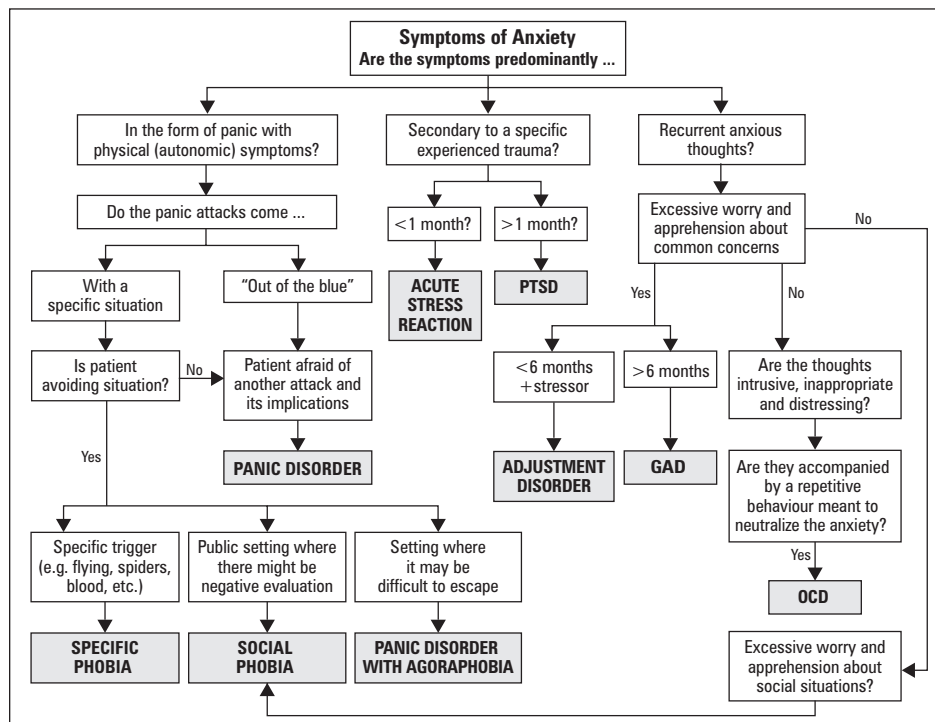

Figure 4. Differentiating Anxiety Disorders

Adapted from: Anxiety Review Panel. Evans M, Bradwejn J, Dunn L (Eds) (2000). *Guidelines for the Treatment of Anxiety Disorders in Primary Care*. Toronto: Queen's Printer of Ontario, pp. 41.

Management

- patient education: emphasize prevalence, good recovery rate of anxiety conditions
- lifestyle advice: decrease caffeine and alcohol intake, exercise, relaxation techniques
- self-help materials, community resources (e.g. support groups)
- cognitive behavioural therapy: cognitive interventions, exposure therapy, etc.
- pharmacotherapy
 - for GAD
 - ♦ 1st line – escitalopram, paroxetine, sertraline, venlafaxine XR
 - antidepressants better for depression and ruminative worry than benzodiazepines
 - ♦ 2nd line – benzodiazepines, bupropion XL, buspirone, imipramine, pregabalin
 - ♦ 3rd line – mirtazapine, citalopram, trazodone, hydroxyzine, adjunctive olanzapine, risperidone
 - 3rd line therapy may be used as an adjunct or used for those patients who fail 1st and 2nd line therapy alone or combined

- ♦ benzodiazepines can be used at any time for severe agitation/anxiety
 - due to side effects, dependence and withdrawal issues, benzodiazepines are best used on a short-term basis (i.e. 1-2 months)
- ♦ beta-blockers are not recommended
- ♦ therapy should continue for at least 1 year after relief of symptoms
- for pharmacotherapy specific to other types of anxiety, see [Psychiatry](#), PS13

Commonly feared situations include: public speaking, eating, drinking, writing in front of others, using public restrooms, speaking on the telephone and social gatherings.

SOCIAL PHOBIA

- a marked and persistent fear of one or more social or performance situations in which the person is exposed to unfamiliar people or to possible scrutiny by others

Epidemiology

- lifetime prevalence rate of up to 16%; F:M = 1.5:1
- often begins in early childhood and adolescence
- can lead to significant psychiatric comorbidity including depression, other anxiety disorders, alcohol and substance abuse and eating disorders

History

- fear of being humiliated or embarrassed in one or more social or performance situations
- fear is recognized as excessive or unreasonable
- avoidance, anticipation and distress of the social situation interferes significantly with social and occupational functioning
- can often present with somatic complaints of insomnia, fatigue, palpitations, chest pain, shortness of breath, dizziness, trembling hands, sweating, blushing and GI complaints

Physical

- symptoms of hyperhidrosis, tremor, blushing, stuttering, hypertension and tachycardia
- thorough mental status examination

Management

- cognitive behavioural therapy
- exposure therapy, cognitive restructuring and social skills training to decrease anxiety and weaken the tendency to avoid social situations
 - exposure therapy is the most well established therapeutic technique
- pharmacotherapy
 - effective treatments include SSRIs, MAOIs and anxiolytics; no TCAs
 - SSRIs are preferred because of effectiveness and lack of significant side effects
 - beta-blocker or benzodiazepine in acute social situations

Asthma/COPD

- see [Respirology](#), R7

Definition

- asthma
 - chronic but reversible airway inflammation characterized by periodic attacks of wheezing, shortness of breath, chest tightness, and coughing
 - airways hyper-responsive to triggers/antigens leading to acute obstructive symptoms by bronchoconstriction, mucous plugs and increased inflammation
 - cannot be diagnosed at first presentation
 - pulmonary function tests can be done from age 6
 - peak flow meters are useful in the office for monitoring
 - called Reactive Airway Disease until recurrent presentations
- chronic obstructive pulmonary disease (COPD)
 - a group of chronic, progressive, expiratory lung diseases characterized by limited airflow with variable degrees of air sac enlargement and lung tissue destruction
 - emphysema and chronic bronchitis are the most common forms of COPD

Differential Diagnosis of Asthma

- Chronic obstructive pulmonary disease
- Cystic fibrosis
- Vocal cord dysfunction
- Congestive heart failure
- Mechanical obstruction of airways (e.g. tumours)

Table 12. Differentiating COPD from Asthma

	COPD	Asthma
Age of Onset	Usually in 6th decade	Any age (but 50% of cases diagnosed in children < 10 yo)
Role of Smoking	Directly related	Known trigger
Reversibility of Airflow Obstruction	Airflow obstruction is chronic and persistent	Airflow obstruction is episodic and usually reversible with therapy
Evolution	Slow, cumulative disabling pattern	Episodic, less than 50% will outgrow
History of Allergy	Infrequent	Over 50% patients
Precipitators	Environmental irritants (air pollution), cigarette smoking, antiprotease deficiency, viral infection, occupational exposure (firefighters, dusty jobs)	Environmental irritants (dust, pollen), furry animals, cold air, exercise, URTIs, cigarette smoke, use of beta-blockers/ASA
Symptoms/Signs	Chronic cough, sputum and/or dyspnea	Wheeze (hallmark symptom), dyspnea, chest tightness, cough which is worse in cold, at night, and in early AM prolonged expiration
Diffusion Capacity	Decreased (more so in pure emphysema)	Normal (for pure asthma)
Hypoxemia	Chronic in advanced stages	Not usually present Episodic with severe attacks
Spirometry	May have improvement with bronchodilators but not universally seen	Marked improvement with bronchodilators or steroids
Chest X-ray	Often normal Increased bronchial markings (chronic bronchitis) and chronic hyperinflation (emphysema) often co-exist	Often normal or episodic hyperinflation Hyperinflation during asthma attack
Management	First line: ipratropium bromide (Atrovent®) Others: salbutamol (Ventolin®), tiotropium bromide (Spiriva®), fluticasone (Flovent®), oral prednisone, oxygen, salmeterol (Serevent®) at bedtime Get flu shot and Pneumovax®	Combination of rescue medications (SABAs) taken on prn basis and maintenance medications (see sidebar) taken on a regular basis to achieve control of asthma symptoms Maintenance medications: Step 1: Low-dose ICS Step 2: Medium/high-dose ICS or low-dose ICS plus either LABA, LT modifier, or long-acting theophylline Step 3: Medium/high-dose ICS plus either LABA, LT modifier, or long-acting theophylline Step 4: As above plus immunotherapy ± oral glucocorticosteroids + flu shot and Pneumovax®

SABA = short-acting beta-agonist LABA = long-acting beta-agonist ICS = inhaled glucocorticosteroids LT modifier = leukotriene modifier

When prescribing Ventolin®, watch out for signs of hypokalemia: lethargy, irritability, paresthesias, myalgias, weakness, palpitations, nausea, vomiting, polyuria.

Signs of Poorly Controlled Asthma

- Beta-2 agonist use > 4x/wk
- Asthma-related absence from work/school
- Exercise induced asthma
- Night-time symptoms > 1x/wk

What Colour is Your Inhaler?

Name	Body/Cap Colour
Beta-2-agonists	
Ventolin®	light blue/navy
Serevent®	teal/light teal
Bricanyl®	blue/white
ICS	
Flovent®	orange/peach
Pulmicort®	white/brown
Combined	
Advair®	purple discus
Symbicort®	red/white
Other	
Atrovent®	clear/green
Combivent®	clear/orange
Spiriva®	white/turquoise

Benign Prostatic Hyperplasia (BPH)

- see Urology, U7

Definition

- hyperplasia of the stroma and epithelium in the periurethral transition zone

History and Physical

- include current/past health, surgeries, trauma, current and OTC meds (see Table 13)
- physical exam must include DRE for size, symmetry, nodularity, and texture of prostate (prostate is symmetrically enlarged, smooth and rubbery in BPH)

Investigations

- urinalysis for microscopic hematuria (common sign)
- serum PSA: protein produced by prostatic tissue
 - increased PSA in a younger man is more often due to cancer than other causes
 - an abnormality on DRE or PSA should trigger further assessment
 - discuss test with men at increased risk of prostate cancer (FHx, African ancestry) or who are concerned about development of prostate cancer
 - considered normal when <4.0 ng/mL; but must take into account patient's age and rate of PSA increase (PSA velocity)
 - if between 4-10 ng/mL: consider measuring free/total PSA
 - if >10 ng/mL, can diagnose prostate pathology
 - PSA testing is inappropriate in men with a life expectancy less than 10 years
 - PSA should not be measured in patients with an acute UTI

Differential Diagnosis

- Prostate cancer
- Urethral obstruction
- Bladder neck obstruction
- Neurogenic bladder
- Cystitis
- Prostatitis

- other
 - Cr, BUN
 - post-void residual volume by ultrasound
 - uroflow
 - patient voiding diary, International Prostate Symptom Score
- tests NOT recommended as part of routine initial evaluation include:
 - cystourethroscopy
 - cytology
 - prostate ultrasound or biopsy
 - IVP

Table 13. Symptoms of BPH

Obstructive Symptoms	Irritative Symptoms	Late Complications
Hesitancy (difficulty starting urine flow)	Urgency	Hydronephrosis
Diminution in size and force of urinary stream	Frequency	Loss of renal concentrating ability
Stream interruption (double voiding)	Nocturia	Systemic acidosis
Urinary retention (bladder does not feel completely empty)	Urge incontinence	Renal failure
Post-void dribbling	Dysuria	
Overflow incontinence		

Management

- referral to urologist if moderate to severe symptoms
- conservative: for patients with mild symptoms or moderate/severe symptoms considered by the patient to be non-bothersome
 - fluid restriction (avoid alcohol and caffeine)
 - avoidance/monitoring of certain medications (e.g. antihistamines, diuretics, antidepressants, decongestants)
 - pelvic floor exercises
 - bladder retraining – organized voiding
- pharmacological: for moderate/severe symptoms
 - alpha receptor antagonists [e.g. terazosin (Hytrin®), doxazosin (Cardura®), tamsulosin (Flomax®), alfuzosin (Xatral®)]
 - ♦ relaxation of smooth muscle around the prostate and bladder neck
 - 5-alpha reductase inhibitor [e.g. finasteride (Proscar®)]
 - ♦ only for patients with demonstrated prostatic enlargement due to BPH
 - ♦ inhibits enzyme responsible for conversion of testosterone into DHT thus reducing growth of prostate
 - phytotherapy (e.g. saw palmetto berry extract, *Pygeum africanum*)
 - ♦ more studies required before being recommended as standard therapy
 - ♦ considered safe
- surgical:
 - TURP: transurethral resection of the prostate
 - ♦ absolute indications: failed medical therapy, intractable urinary retention, benign prostatic obstruction leading to renal insufficiency
 - ♦ complications include: impotence, incontinence, ejaculatory difficulties (retrograde ejaculation), decreased libido
 - TUIP: transurethral incision of the prostate – for prostates <30 g
 - other invasive procedures: TUVAP (transurethral electrovaporization of prostate), laser prostatectomy, open prostatectomy
 - minimally invasive surgical therapies (MIS):
 - ♦ TUMT: transurethral microwave therapy
 - ♦ TUNA: transurethral needle ablation
 - ♦ stents: for severe urinary obstruction in non-surgical candidate

**Differential Diagnosis**

- URTI
- Asthma
- Acute exacerbation of chronic bronchitis
- Sinusitis
- Pneumonia
- Bronchiolitis
- Pertussis
- Environmental/occupational exposures
- Post-nasal drip
- Others: reflux esophagitis, CHF, bronchogenic CA, aspiration syndromes, CF, foreign body

Bronchitis (Acute)**Definition**

- acute infection of the tracheobronchial tree causing inflammation leading to bronchial edema and mucus formation

Epidemiology

- 5th most common diagnosis in family medicine, most common is URTI

Etiology

- 80% viral: rhinovirus, coronavirus, adenovirus, influenza, parainfluenza, RSV
- 20% bacterial: *M. pneumoniae*, *C. pneumoniae*, *S. pneumoniae*

Investigations

- acute bronchitis is typically a clinical diagnosis
- sputum culture/Gram stain is not very informative
- CXR if suspect pneumonia (cough >3 weeks, abnormal vital signs, localized chest findings) or CHF
- pulmonary function tests with methacholine challenge if suspect asthma

Management

- primary prevention: frequent hand washing, smoking cessation, avoid irritant exposure
- symptomatic relief: rest, fluids (3-4 L/day when febrile), humidity, analgesics and antitussives as required
- bronchodilators may offer improvement of symptoms (e.g. albuterol)
- current literature does not support routine antibiotic treatment for the management of acute bronchitis because it is most likely to be caused by a viral infection
 - antibiotics may be useful if elderly, comorbidities, pneumonia is suspected, or if the patient is toxic (refer to *Antimicrobial Quick Reference*, FM50)
 - antibiotics in children show no benefit

How to Tell if Viral or Bacterial?

Bacterial infections tend to give a higher fever, excessive amounts of purulent sputum production, and may be associated with concomitant COPD.

Note: purulent sputum is not necessarily bacterial.

Chest Pain

- see *Cardiology and Cardiovascular Surgery*, C4 and *Emergency Medicine*, ER22

Differential Diagnosis

Table 14. Differential Diagnosis of Chest Pain

Cardiac	Pulmonary	GI	MSK/Neuro	Psychologic
Angina*	Pneumonia	GERD	Costochondritis	Anxiety
MI*	Pneumothorax*	PUD	Intercostal strain	Panic
Pericarditis*	PE*	Perforated viscus*	Arthritis	Depression
Myocarditis	Pulmonary HTN	Esophageal spasm	Rib fractures	
Aortic dissection*	Lung CA	Cholecystitis	Herpes zoster	
Endocarditis		Hepatitis		

*Emergent

Risk Factors for Coronary Artery Disease

Major

1. Smoking
2. Diabetes
3. Hypertension
4. Hyperlipidemia
5. Family history

Minor

1. Obesity
2. Sedentary lifestyle
3. Age

Investigations

- ECG, CXR, and others if indicated (cardiac enzymes, D-dimers, LFTs, etc.)
- refer to Emergency Department if suspect serious etiology (e.g. aortic dissection, MI)

Management of Common Causes of Chest Pain

- angina/ischemic heart disease
 - acute: nitroglycerin (NTG) (wait 5 minutes between sprays and if no effect after 3 sprays, send to ER)
 - ♦ if inferior MI, NTG will cause patient to become hypotensive
 - long term: see Figure 5
- myocardial infarction (MI)
 - chew ASA STAT, to ER for "MONA" (Morphine, Oxygen, NTG, ASA)
 - ± reperfusion therapy with tPA or streptokinase if within 6 hours (Note: can only use SK once in lifetime)
 - start beta-blocker (e.g. metoprolol starting dose 12.5 mg PO OD, increase gradually to 50 mg PO bid)
- endocarditis: IV penicillin G 20 million units OD or IV ampicillin 12 g OD
- GERD: antacids, H₂ blockers, PPIs
- costochondritis: NSAIDs

High-Risk Symptoms and Signs of Chest Pain include:

- Severe pain
- Pain for >20 min
- New onset pain at rest
- Severe SOB
- Loss of consciousness
- Hypotension
- Tachycardia
- Bradycardia
- Cyanosis

MI in Elderly Women

Elderly women can often present with dizziness, lightheadedness or weakness, in the absence of chest pain.

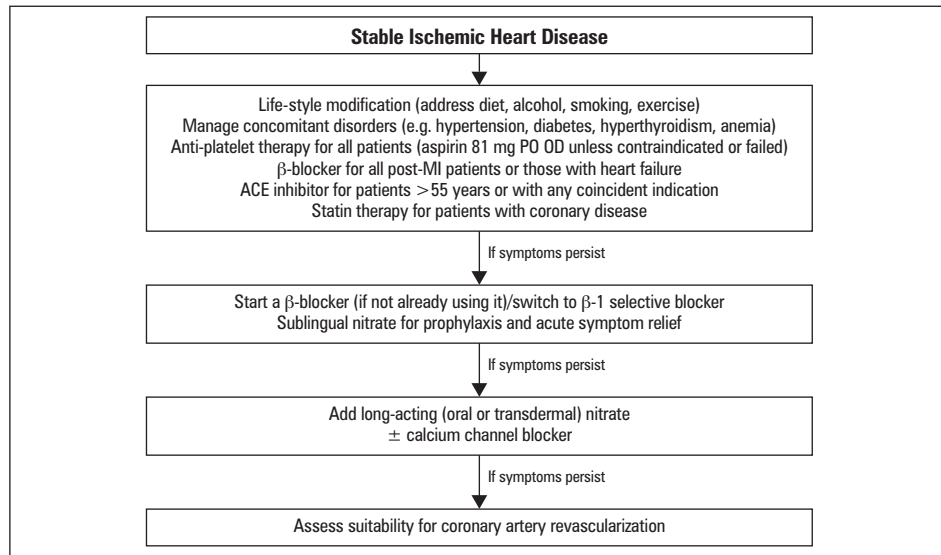

Figure 5. Treatment Algorithm for Stable Ischemic Heart Disease

References: Ontario Drug Therapy Guidelines for Stable Ischemic Heart Disease in Primary Care (2000). *Ontario Program for Optimal Therapeutics*. Toronto: Queen's Printer of Ontario, pp. 10.

Guidelines on the management of stable angina pectoris. *Recommendations of the Task Force of the European Society of Cardiology*; 2006. p63.

Common Cold (Acute Rhinitis)

Common Cold Etiology

PRIMA

Paramyxoviruses
Rhinoviruses
Influenza viruses
Myxoviruses
Adenoviruses

Influenza vs. Colds: A Guide to Symptoms

Features	Flu	Cold
Onset of illness	Sudden	Slow
Fever	High fever	None
Exhaustion level	Severe	Mild
Cough	Dry severe or hacking	±
Throat	Fine	Sore
Nose	Dry and clear	Runny
Head	Achy	Headache-free
Appetite	Decreased	Normal
Muscles	Achy	Fine
Chills	Yes	No

Echinacea for Preventing and Treating the Common Cold

Cochrane Database of Systematic Reviews 2006; Issue 1

This systematic review of 16 trials assessed the effect of Echinacea in preventing and treating common colds. Trials compared preparations containing Echinacea with placebo, no treatment, or an alternative common cold treatment. Variations in preparations and quality of Echinacea made meta-analysis difficult, but in general, results suggested some preparations of Echinacea may be better than placebo.

Conclusions: Echinacea preparations vary widely. Some preparations with *E. purpurea* may be effective but results are inconsistent.

Definition

- viral upper respiratory tract infection (URTI) with inflammation

Epidemiology

- most common diagnosis in family medicine; peaks in winter months
- incidence: adults = 2-4/year, children = 6-10/year
- organisms
 - mainly rhinoviruses (30-35% of all colds)
 - others: coronavirus, adenovirus, RSV, influenza, parainfluenza, echovirus, coxsackie virus
- incubation: 1-5 days
- transmission: person-person contact via secretions on skin/objects and by aerosol droplets

Risk Factors

- psychological stress, excessive fatigue, allergic nasopharyngeal disorders, smoking, sick contacts

Clinical Features

- symptoms
 - local – nasal congestion, clear to mucopurulent secretions, sneezing, sore throat, conjunctivitis, cough
 - general – malaise, headache, myalgias, mild fever
- signs
 - boggy and erythematous nasal/oropharyngeal mucosa, enlarged lymph nodes
 - normal chest exam
- complications
 - secondary bacterial infection: otitis media, sinusitis, bronchitis, pneumonia
 - asthma/COPD exacerbation

Differential Diagnosis

- allergic rhinitis, pharyngitis, influenza, laryngitis, croup, sinusitis, bacterial infections

Management

- patient education
 - symptoms peak at 1-3 days and usually subside within 1 week
 - cough may persist for days to weeks after other symptoms disappear
 - no antibiotics indicated because of viral etiology
 - secondary bacterial infection can present within 3-10 days after onset of cold symptoms
- prevention
 - frequent hand washing, avoidance of hand to mucous membrane contact, use of surface disinfectant

- symptomatic relief
 - rest, hydration, gargling warm salt water, steam
 - analgesics and antipyretics: acetaminophen, ASA (not in children because risk of Reye's syndrome)
 - cough suppression: dextromethorphan or codeine if necessary
 - decongestants, antihistamines
 - zinc gluconate lozenge use is controversial
- patients with reactive airway disease will require increased use of bronchodilators and inhaled steroids

Zinc for the Common Cold

Cochrane Database of Systematic Reviews 2006; Issue 3; Last amendment: 1999

This systematic review of 7 randomized control trials investigated the effects of zinc lozenges for cold (acute upper respiratory tract infection) symptoms. Two trials suggested the lozenges were effective in reducing severity and duration of symptoms; overall, the lozenges did not appear to be effective.

Conclusions: The evidence for zinc lozenges treating the common cold is inconclusive, and there is a potential for side effects.

Contraception

- see Gynecology, GY18

Table 15. Methods of Contraception

	Advantages	Disadvantages
Combined OCP	Effectiveness: 99.9% with perfect use, 97-99% with typical use, cycle control, ↓ dysmenorrhea, ↓ menstrual flow, ↓ ovarian cancer, ↓ endometrial cancer, ↓ risk of fibroids, ↓ acne, ↓ hirsutism	Irregular bleeding, systemic hormonal side effects (breast tenderness, nausea, mood changes), no STI protection, slightly increased risk of venous thromboembolism (VTE), MI, and stroke, decreased quantity of breast milk postpartum
Progestin Only Pill (e.g. Micronor®)	At least 95% effective with perfect use, ↓ menstrual flow, ↓ cramping, no ↑ risk of VTE, MI or stroke, suitable for postpartum	Irregular bleeding, no STI protection, contraceptive reliability requires taking pill at the same time each day (within 3 hours), no pill free interval
Transdermal Patch (e.g. Evra®)	Same as OCP, easy to use, changed weekly, 99% effective with correct use	Same as OCP, skin irritation
NuvaRing® (inserted by patient)	Same as OCP, easy to use (in for 3 weeks, out for 1), less systemic hormonal side effects, 99% effective with correct use	Same as OCP, vaginitis, some women may be uncomfortable with self-insertion
DMPA IM progesterone injection q12 wks (e.g. DepoProvera®)	99.7% effective against pregnancy, infrequent dosing, ↓ menstrual flow or amenorrhea, ↓ risk of endometrial cancer	Irregular bleeding, delayed return of fertility, no STI protection, systemic hormonal side effects (most common is headache), weight gain, ↓ bone mineral density (check after 5 years)
Male Condom	97% effective against pregnancy and STIs when used properly. When used properly WITH spermicide they are close to 99.9% effective, no Rx required	Latex allergy, irritation, only effective before the expiry date, must be applied properly, can only be used once
Diaphragm	92-96% effective with perfect use, non-hormonal, female-controlled method of contraception, decreased risk of cervical cancer	Must be left in for 6h after intercourse, must be used with spermicide, incomplete STI protection, latex allergy, must be fitted by health care worker, increased risk of UTI, risk of toxic shock syndrome
Sponge	One-size-fits-all barrier method, does not require fitting by MD, available in pharmacies, 90% effective without a condom, 98% effective with a condom	Relatively expensive, only ~60% effective in parous women, incomplete STI protection, risk of toxic shock syndrome
Intrauterine Device (IUD)	99% effective against pregnancy, effective for 5 yrs, no daily regimen required, can be easily removed, ideal in post-partum women	No STI protection, increased relative risk of PID in first month, must be inserted by MD, risk of post-insertion vaso-vagal response, risk of uterine rupture is 0.6-1.6 per 1000, 2-10% expulsion rate
Levonorgestrel IUD (e.g. Mirena®)	↓ menstrual flow, less systemic hormonal side effects than OCP	Hormonal side effects (see <i>combined OCP</i>), expensive (~\$400)
Copper IUD (e.g. Nova T®)	↓ risk of endometrial cancer, less expensive (~\$170)	Irregular bleeding or ↑ menstrual flow, 6-20% women discontinue use in first 5 yrs because of pain or ↑ bleeding
Fertility Awareness/Natural Family Planning (e.g. symptothermal method)	Effectiveness: 95-98% with perfect use, 75-88% with typical use, increased awareness of gynecological health, reasonable for couples for whom an unplanned pregnancy would be acceptable	High probability of failure if not used consistently and correctly, no STI protection
Lactational amenorrhea	Very effective in breastfeeding women if menses not returned, fully or nearly fully breastfeeding baby and baby is under 6 months old	Not effective if infant receives any food supplementary to breastfeeding Must breastfeed regularly, even through the night (at least q6h)

Emergency Contraception (EC)

- hormonal EC (Yuzpe® or Plan B®, usually 2 doses taken 12 hrs apart) or post-coital IUD insertion
- hormonal EC is effective if taken within 72 hrs of unprotected intercourse (reduces chance of pregnancy by 75-85%), most effective if taken within 24 hrs, does not affect an established pregnancy
- post-coital IUDs inserted within 5 days of unprotected intercourse are significantly more effective than hormonal EC (reduces chance of pregnancy by ~99%)
- pregnancy test should be performed if no menstrual bleeding within 21 days of either treatment
- advance provision of hormonal emergency contraception increases the use of emergency contraception without decreasing the use of regular contraception
- pharmacists across Canada can now dispense Plan B® without a doctor's prescription (as of April 2005)

Absolute Contraindications to Combined OCP

- Known/suspected pregnancy
- Undiagnosed abnormal vaginal bleeding
- Thromboembolic disorders
- Cerebrovascular or coronary artery disease
- Estrogen dependent tumours (breast, uterus)
- Impaired liver function with acute liver disease
- Congenital hypertriglyceridemia
- Smoker >35 years old
- Migraines with focal neurological symptoms
- Uncontrolled hypertension

**Differential Diagnosis****Common Causes**

- Upper airway cough syndrome (postnasal drip)
- Asthma
- GERD
- Non-asthmatic eosinophilic bronchitis

Other Causes

- ACE inhibitors
- Aspiration
- Bronchiectasis
- Cystic fibrosis
- Chronic interstitial lung disease
- Lung/laryngeal cancer
- Pertussis
- Psychogenic
- Restrictive lung disease
- TB, atypical mycobacterium, and other chronic lung infections

Cough

History and Physical

- duration (chronic >3 months), onset, frequency, quality (dry vs. productive), sputum characteristics, provoking/relieving factors, recent changes
- associated symptoms: fever, dyspnea, hemoptysis, wheezing, chest pain, orthopnea, PND, rhinitis
- constitutional symptoms: fever, chills, fatigue, night sweats
- risk factors: smoking, occupation, exposure, family history of lung CA or other CA, TB status, recent travel
- medications (ACE inhibitors), allergies
- PMH: lung (asthma, COPD, CF), heart (CHF, MI, arrhythmias), chronic illness
- vitals including O₂ saturation, respiratory exam, HEENT and precordial exam

Investigations

- guided by findings on history and physical
 - consider throat swab, CXR, sputum culture, test for acid-fast bacilli
 - refer to respirology for PFTs as appropriate

Dementia

- see Psychiatry, PS18

Epidemiology

- 10% in patients over the age of 65, 25% in patients over the age of 85, 50% in patients over the age of 90
- prevalence increases with age, Down syndrome and head trauma
- differential diagnosis: Alzheimer's dementia, vascular dementia, Lewy-Body dementia, frontotemporal dementia

Investigations

- history, physical, MMSE
- investigations are completed to exclude reversible causes of dementia and should be selected based on the clinical circumstances
- CBC, liver, thyroid, renal function tests, serum electrolytes, serum glucose, vitamin B₁₂, folate, VDRL, HIV, SPECT, head CT, EEG

Management

- treat and prevent reversible causes
- provide orientation cues (e.g. calendars, clocks) and optimize vision and hearing
- family education, counselling and support (respite programs, group homes)
- pharmacologic therapy: NMDA receptor antagonists and cholinesterase inhibitors slow rate of cognitive decline; low-dose neuroleptics and anti-depressants can be used to treat behavioral and emotional symptoms
- 20% of patients develop clinical depression, most commonly seen in vascular dementia

Depression

- see Psychiatry, PS7

Etiology

- often presents as non-specific complaints (e.g. chronic fatigue, pain)
- depression is a clinical diagnosis and tests are done in order to rule out other causes of symptoms
- 2/3 of depressed persons may not receive appropriate treatment for their depression
- identification and early treatment improve outcomes

Screening Questions

- Are you depressed? (high specificity and sensitivity)
- Have you lost interest or pleasure in the things you usually like to do? (anhedonia)
- Do you have problems sleeping? (for those not willing to admit depression)

Assessment

- risk factors
- personal or family history of depression
- medications and potential substance abuse problems
- suicidality/homicidality
 - fill out Form 1 (in Ontario): application by physician to hospitalize a patient against his/her will for psychiatric assessment (up to 72 hours)

**Differential Diagnosis**

- Other psychiatric disorders (e.g. anxiety, personality, bipolar, schizoaffective, SAD, substance abuse/withdrawal)
- Early dementia
- Endocrine (hyper/hypothyroidism, DM)
- Liver failure, renal failure
- Chronic fatigue syndrome
- Vitamin deficiency (pernicious anemia, pellagra)
- Medication side effects (β-blockers, benzos)
- Infections (mononucleosis)
- Menopause
- Cancer (50% of patients with tumours, especially of brain, lung and pancreas, develop symptoms of depression before the diagnosis of cancer is made)

- functional impairment (e.g. work, relationships)
- at least 5 out of 9 criteria including anhedonia or depressed mood ≥ 2 weeks for actual diagnosis to be met (see sidebar)
- validated depression rating scales: Beck's depression inventory, Zung's self-rating depression scale, Children's depression inventory
- routine medical workup (physical examination, CBC, TSH, electrolytes, urinalysis, glucose, etc.)

Treatment

- goal: full remission of symptoms and return to baseline psychosocial function
- phases of treatment
 - acute phase (8-12 weeks): relieve symptoms and improve quality of life
 - maintenance phase (6-12 months after symptom resolution): prevent relapse/recurrence, must stress importance of continuing medication treatment for full duration to patients
- treatment can consist of pharmacotherapy alone or psychotherapy alone
- combination of antidepressant drug therapy and psychotherapy results in synergistic effects

Table 16. Common Medications

Class	Examples	Action	Side Effects	Notes
SSRI	paroxetine (Paxil®), fluoxetine (Prozac®), sertraline (Zoloft®), citalopram (Celexa®), fluvoxamine (Luvox®)	Block serotonin reuptake	Sexual dysfunction (impotence, decreased libido, delayed ejaculation, anorgasmia), headache, GI upset, weight loss, tremors, insomnia, fatigue	First line therapy for teens is fluoxetine; paroxetine is not recommended for teens (controversial)
SNRI	venlafaxine (Effexor®)	Block serotonin and NE reuptake	Insomnia, tremors, tachycardia, sweating	
SDRI	bupropion (Wellbutrin®)	Block dopamine and NE reuptake	Headache, insomnia, nightmares, seizures, less sexual dysfunction than SSRIs	
TCA	amitriptyline (Elavil®)	Block serotonin and NE reuptake	Sexual dysfunction, weight gain, tremors, tachycardia, sweating	Narrow therapeutic window, lethal in overdose

Prognosis

- up to 40% resolve spontaneously within 6-12 months
- risks of recurrence: 50% after 1 episode; 70% after 2 episodes; 90% after 3 episodes

Diabetes Mellitus (DM)

- see Endocrinology, E6

Epidemiology

- major health concern, affecting up to 10% of Canadians
- Type 1 Diabetes (DM1): 10-15% of DM, peak incidence age 10-15
- Type 2 Diabetes (DM2): 85-90% of DM, peak incidence age 50-55, up to 60,000 new cases in Canada per year
- gestational diabetes mellitus (GDM): 2-4% of all pregnancies
- incidence of Type 2 DM is rising dramatically as a result of an aging population, rising rates of obesity, and sedentary lifestyles
- leading cause of new-onset blindness and renal dysfunction
- Canadian adults with diabetes are twice as likely to die prematurely, compared to persons without diabetes

Risk Factors

- Type 1 DM
 - personal or family history of autoimmune disease
- Type 2 DM
 - first degree relative with DM
 - age ≥ 40 years
 - obesity (especially abdominal), hypertension, hyperlipidemia, coronary artery disease, vascular disease
 - prior GDM, macrosomic baby (>4 kg)
 - PCOS
 - history of IGT or IFG
 - presence of complications associated with diabetes
- both
 - member of a high risk population (e.g. Aboriginal, Hispanic, Asian or African descent)

Criteria for Depression

- M** Depressed Mood
- S** Increased/decreased Sleep
- I** Decreased Interest
- G** Guilt
- E** Decreased Energy
- C** Decreased Concentration
- A** Increased/decreased Appetite
- P** Psychomotor agitation/retardation
- S** Suicidal ideation

Must Ask About/Rule Out

- Bipolar/manic/hypomanic episodes
- Psychosis
- Anxiety
- Bereavement
- Substance use/abuse/withdrawal
- Suicidal/homicidal ideation

Common Antidepressants and Dosing

Drug	Starting Dose	Maximum Dose
citalopram (Celexa®)	20 mg PO OD	60 mg PO OD
escitalopram (Cipralex®)	10 mg PO OD	20 mg PO OD
fluoxetine (Prozac®)	20 mg PO q am	80 mg PO OD
paroxetine (Paxil®)	20 mg PO q am	50 mg PO OD
sertraline (Zoloft®)	50 mg PO OD	200 mg PO OD
fluvoxamine (Luvox®)	50 mg PO qhs	300 mg PO OD
venlafaxine (Effexor®)	75 mg PO OD	375 mg PO OD
(Effexor XR®)	37.5 mg PO OD	225 mg PO OD
bupropion (Wellbutrin®-immed)	100 mg PO bid	450 mg PO OD
(Sustained release)	100 mg PO qam	400 mg PO OD
amitriptyline (Elavil®)	25 mg PO qhs	300 mg PO OD
mirtazapine (Remeron®)	15 mg PO qhs	45 mg PO OD

Combined Pharmacotherapy and Psychological Treatment for Depression: A Systematic Review

Arch Gen Psychiatry 2004; 61(7):714-9

Study: Systematic review of randomized clinical trials.

Patients: 16 trials comprising 1842 patients.

Intervention: Antidepressant treatment alone vs. combination of psychological intervention and antidepressant therapy.

Main outcomes: Efficacy of and adherence to therapy.

Results: Overall, combined therapy was significantly more effective than antidepressant therapy alone (OR 1.86; 95% CI 1.38-2.52), however there was no difference in the rate of dropouts and non-responders in either treatment arm. In studies lasting >12 weeks, combined therapy showed a reduction in dropouts compared to non-responders (OR 0.59; 95% CI 0.39-0.88)

**DM Related Symptoms**

Hyperglycemia: polyphagia, polydipsia, polyuria, weight change, blurry vision, yeast infections

Diabetic ketoacidosis (DKA): fruity breath, anorexia, N/V, fatigue, abdo pain, Kussmaul breathing, dehydration

Hypoglycemia: hunger, anxiety, tremors, palpitations, sweating, headache, fatigue, confusion, seizures, coma

DKA can be triggered by infection, ischemia, infarction, intoxication, medication non-compliance.

**Long Term Complications of Diabetes**

- Microvascular: nephropathy, retinopathy, neuropathy
- Macrovascular: CAD, CVD, PVD

Diagnosis

- persistent hyperglycemia is the hallmark of all forms of diabetes

Table 17. Diagnosis of Insulin Associated Disorders

Condition	Diagnostic Criteria
Diabetes Mellitus	One of the following on 2 occasions: Random BG ≥ 11.1 mmol/L (200 mg/dL) with symptoms of DM (fatigue, polyuria, polydipsia, unexplained weight loss) OR Fasting BG ≥ 7.0 mmol/L (126 mg/dL) OR BG 2 hours post 75 g OGTT ≥ 11.1 mmol/L (200 mg/dL) OR HbA1c $\geq 6.5\%$
Impaired Fasting Glucose (IFG)	Fasting BG = 6.1-6.9 mmol/L (110-124 mg/dL)
Impaired Glucose Tolerance (IGT)	BG 2 hours post 75 g OGTT = 7.8-11.0 mmol/L (141-198 mg/dL)

Screening

- Type 2 DM
 - FBG in everyone ≥ 40 q3 yrs
 - more frequent and/or earlier testing if presence of ≥ 1 risk factor (as previously listed)
- GDM (see *Obstetrics*, OB13)
 - all pregnant women between 24-28 weeks gestation
 - non-fasting 1 hr 50 g OGCT ≥ 10.3 mmol/L (186 mg/dL) is diagnostic
 - if between 7.8-10.2 mmol/L (141-184 mg/dL), do confirmatory fasting 2 hr 75 g OGTT
 - if develop GDM, have a 50% chance of developing Type 2 DM over 20 years

Goals of Therapy**Table 18. Goals of Therapy in Diabetes Mellitus**

General	Avoid complications (e.g. ketoacidosis, hyperglycemia, infection) Prevent long-term complications (microvascular and macrovascular) Minimize negative sequelae associated with therapies (e.g. hypoglycemia, weight gain)
Fasting or Preprandial Glucose	Ideal: 4-7 mmol/L (72-126 mg/dL) Suboptimal: 7.1-10 mmol/L (128-180 mg/dL); action may be required Inadequate: > 10.0 mmol/L (180 mg/dL); action is required
HbA1c	≤ 0.07 or ≤ 0.065 in some type 2 DM patients at risk for nephropathy Suboptimal: 0.07-0.084 Inadequate: > 0.084
2 Hours Postprandial Glucose	5-10 mmol/L (90-180 mg/dL) if HbA1c target met 5-8 mmol/L (90-144 mg/dL) if HbA1c target not met
Blood Pressure	$< 130/80$ in adults (DM and HTN guidelines)
Lipids	LDL < 2.0 mmol/L (36 mg/dL) Triglycerides < 1.5 mmol/L (27 mg/dL) Total cholesterol/HDL ratio < 4.0 mmol/L (72 mg/dL)

Assessment and Monitoring**Table 19. Assessment and Monitoring**

	Initial Assessment	q2-4months	Annually
History	<ul style="list-style-type: none"> • Symptoms of hyperglycemia, ketoacidosis, hypoglycemia • Past medical history • Functional inquiry • Family history • Risk factors • Medications • Sexual function • Lifestyle 	<ul style="list-style-type: none"> • Diabetes-directed history • Screen for awareness and frequency of hypoglycemia and DKA • Glucose monitoring • Use of insulin and oral agents 	<ul style="list-style-type: none"> • Diabetes-directed history • Screen for awareness and frequency of hypoglycemia and DKA • Glucose monitoring • Use of insulin and oral agents • Sexual function • Lifestyle counselling • Psychosocial issues
Physical	<ul style="list-style-type: none"> • General: Ht, Wt, BMI, BP • Head and neck: fundoscopy, thyroid exam • Cardiovascular exam: signs of CHF, pulses, bruits • Abdominal exam (e.g. for organomegaly) • Hand/foot/skin exam • Neurological exam 	<ul style="list-style-type: none"> • Wt, BP, BMI, WC • Foot exam for sensation, ulcers, or infection 	<ul style="list-style-type: none"> • Complete neuro exam for peripheral neuropathy • Remainder of exam as per PHE

Table 19. Assessment and Monitoring (continued)

	Initial Assessment	q2-4months	Annually
Investigations	<ul style="list-style-type: none"> • FBG, HbA1c, fasting lipids, microalbumin:creatinine ratio • ECG 	<ul style="list-style-type: none"> • HbA1c q3 months • FBG as needed 	<ul style="list-style-type: none"> • Fasting lipid profile • Resting or exercise ECG if age > 35 • Dipstick analysis for gross proteinuria; if negative: annual microalbuminuria screening with random albumin:creatinine ratio for Type 2 and Type 1 (5 yrs post puberty) • If positive: 24-hr urine for endogenous creatinine clearance rate and microalbuminuria q6-12months
Management	<ul style="list-style-type: none"> • Nutritional and physical education • Consider referral to diabetes education program if available • Monitoring BG: explain methods and frequency • Medication counselling: oral hypoglycemics and/or insulin, method of administration, dosage adjustments • Ophthalmology consult <ul style="list-style-type: none"> • Type 1 within 5 yrs • Type 2 at diagnosis 	<ul style="list-style-type: none"> • Assess progress towards long-term complications • Adjust treatment plan if necessary 	<ul style="list-style-type: none"> • Calibrate home glucose monitor • Arrange ophthalmology follow-up annually for Type 1 and q2years for Type 2 • Influenza vaccination annually

Long-term Non-pharmacological Weight Loss Interventions for Adults with Prediabetes
Cochrane Database of Systematic Reviews 2005; Issue 2

A meta-analysis, using 9 studies comprising 5168 patients, investigated the effectiveness of diet control, physical activity, behavioural weight programs and weight control interventions in adults with prediabetes. The analysis was limited by heterogeneous patient populations, but when compared with usual care, weight loss was 2.8 kg and BMI decrease was 1.3 kg/m² at one year. Modest but non-significant improvements in glycemic control, BP and blood lipid concentrations were noted. Studies with a follow-up of 3-6 years showed a significant decrease in diabetes onset when compared with controls.

Dietary advice for Treatment of Type 2 DM in Adults
Cochrane Database of Systematic Reviews 2007; Issue 3

A meta-analysis, using 36 articles reporting a total of 18 trials following 1467 participants, showed that there is no high quality data on the efficacy of dietary treatment of type 2 diabetes. After 6 and 12 months, adoption of exercise improved glycated hemoglobin.

Nonpharmacologic Management

- diet
 - all diabetics should see a registered dietician
 - strive to attain healthy body weight
 - decrease combined saturated fats and trans-fatty acids to <10% of calories
 - avoid simple sugars, encourage complex carbohydrates, choose low glycemic-index foods
- physical activity and exercise
 - encourage 30-45 minutes of moderate exercise 4-7 days/week
 - promote cardiovascular fitness: increases insulin sensitivity, lowers BP and improves lipid profile
 - if insulin treated, may require alterations of diet, insulin regimen, injection sites and self-monitoring

Self-monitoring of Blood Glucose

- Type 1 DM: 3 or more self-tests/day is associated with a 1% reduction in HbA1c
- Type 2 DM: optimum frequency of self-tests remains unclear
- if FBG >14 mmol/L, perform ketone testing to rule out DKA
- if bedtime level is <7 mmol/L, have bedtime snack to reduce risk of nocturnal hypoglycemia

**Figure 6. Types of Insulin Preparation**

Calculate Total Insulin Required:

Type 1: 0.5-0.7 units/kg/day
 Type 2: 0.3 units/kg/day

Oral Hypoglycemics (DM2)

- available agents
 - biguanide: metformin (Glucophage®)
 - thiazolidinedione: troglitazone (Rezulin®), rosiglitazone (Avandia®)
 - alpha glucosidase inhibitor: acarbose (Precose®)
 - nonsulfonylureas: nateglinide (Starlix®), repaglinide (Gluconorm®)
 - sulfonylureas: glyburide (DiaBeta®), glimepiride (Amaryl®), gliclazide (Diamicon®)
 - DPP-4 inhibitor: sitagliptin (Januvia®)

Health Canada Recommendations on Management of Rosiglitazone Use in DM2

Rosiglitazone is indicated for:

- Use as monotherapy, in patients not controlled by diet and exercise alone
- For patients inadequately controlled on metformin or sulfonylurea, rosiglitazone should be added to, not substituted for, metformin or sulfonylurea
- In Canada, rosiglitazone is not approved for use:
 - with insulin therapy
 - with the combination of metformin AND sulfonylurea
 - in patients with pre-diabetes
- Contraindicated in patients with NYHA Class III and IV cardiac status
- Should be used with caution in any patient with NYHA Class I and II cardiac status
- Patients should be monitored for signs and symptoms of fluid retention, edema, and rapid weight gain
- Maximum daily dose used in combination with sulfonylurea should not exceed 4 mg

Metformin Monotherapy for Type 2 Diabetes Mellitus

Cochrane Database of Systematic Reviews 2005; Issue 3
 A Cochrane Review of 29 trials with 37 arms (5259 participants) compared metformin with sulfonylureas, placebo, diet, thiazolidinediones, insulin, meglitinides, and glucosidase inhibitors. The authors concluded that metformin may prevent some vascular complications and mortality in overweight and obese DM2 patients and as such may be considered first line therapy. There is no evidence that the studied alternative therapies have more benefit for glycaemia control, body weight, or lipids than does metformin.

Other Medications Used in DM

- ACE inhibitors for:
 - all hypertensive DM patients
 - elevated microalbuminuria (30-300 mg albumin in 24 h)
 - overt nephropathy (>300 mg albumin in urine in 24 h)
 - ARBs are second line for these conditions
- ASA for:
 - all diabetics, unless contraindicated
- statins
 - as required to attain target lipid profile

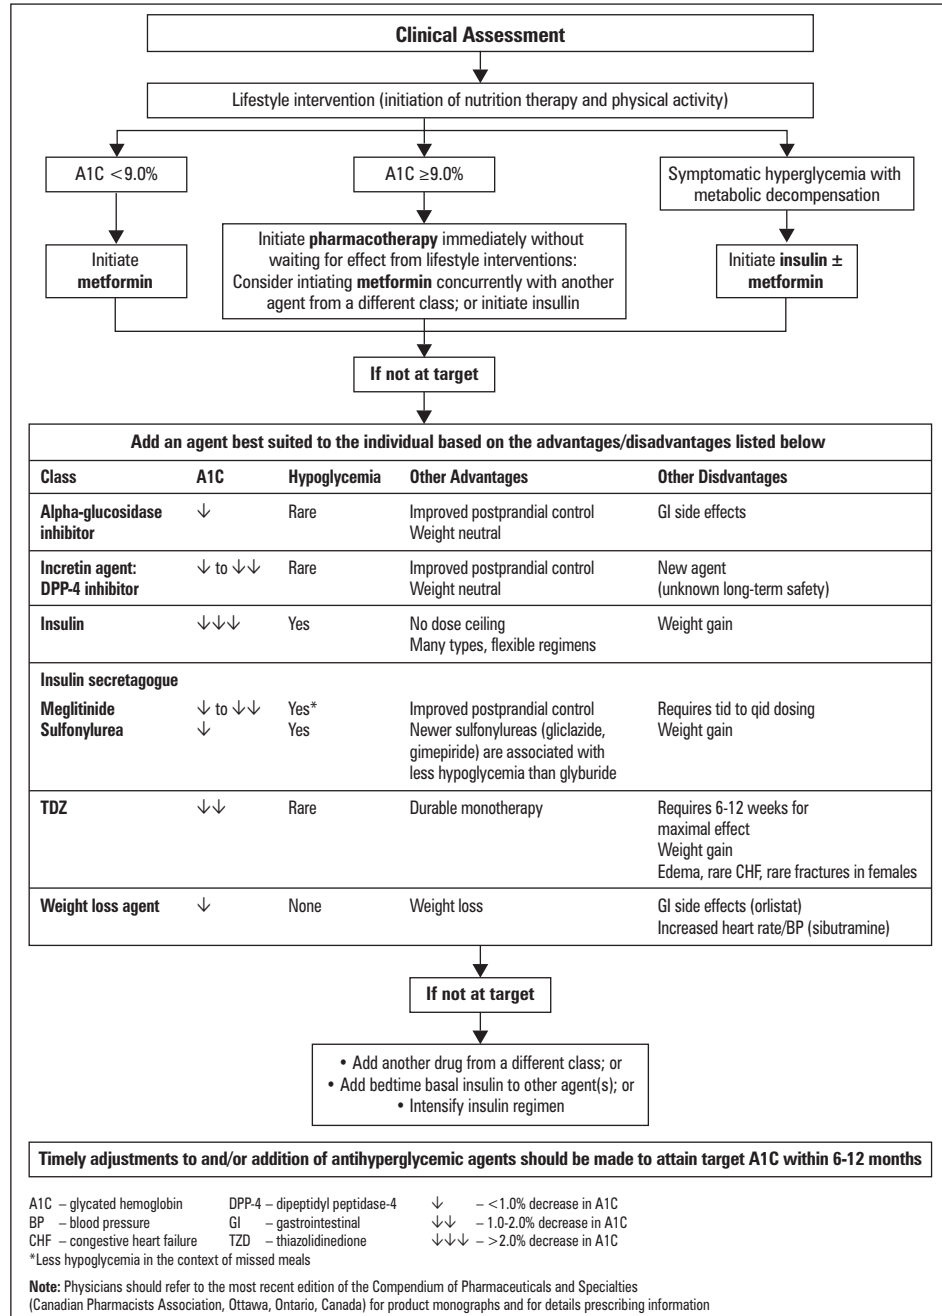

Figure 7. Management of Hyperglycemia in Type 2 Diabetes

Canadian Diabetes Association Clinical Practice Guidelines Expert Committee. Canadian Diabetes Association 2008 clinical practice guidelines for the prevention and management of diabetes in Canada. *Can J Diabetes* 2008; 32(suppl 1):S56 (used with permission).

Diarrhea

- see Gastroenterology, G14

Definition

- passage of frequent unformed stools (>200 g of stool/24 hours)
- can be acute (<14 days duration) or chronic (>14 days duration)

Etiology and Clinical Features

- acute diarrhea:
 - majority of cases are self-limiting
 - most commonly caused by viral infection (e.g. rotavirus)
 - fever and bloody stools increase probability of bacterial infection
 - consider *C. difficile* infection if recent hospitalization, recent antibiotic use, age >65, immunosuppression
- chronic diarrhea:
 - most commonly of non-infectious etiology
 - common causes include drugs (laxatives, antibiotics), infection (bacteria, parasites), inflammation (IBD, diverticulitis), neoplasia (colon cancer), malabsorption, maldigestion, IBS, and idiopathic

Treatment

- chronic diarrhea: nonspecific treatment often required before workup is complete
 - antidiarrheal opiates (e.g. loperamide) – most effective nonspecific treatment
 - ♦ should be used on a scheduled basis before meals rather than PRN
 - fibre (e.g. psyllium) – commonly used as adjunctive treatment
 - oral rehydration solution – offset electrolyte imbalances
 - lifestyle and diet changes

Dizziness

- see Otolaryngology, OT6

Epidemiology

- 70% see general practitioners initially; 4% referred to specialists
- frequency proportional to age; commonest complaint of ambulatory patients age >75

Differential Diagnosis

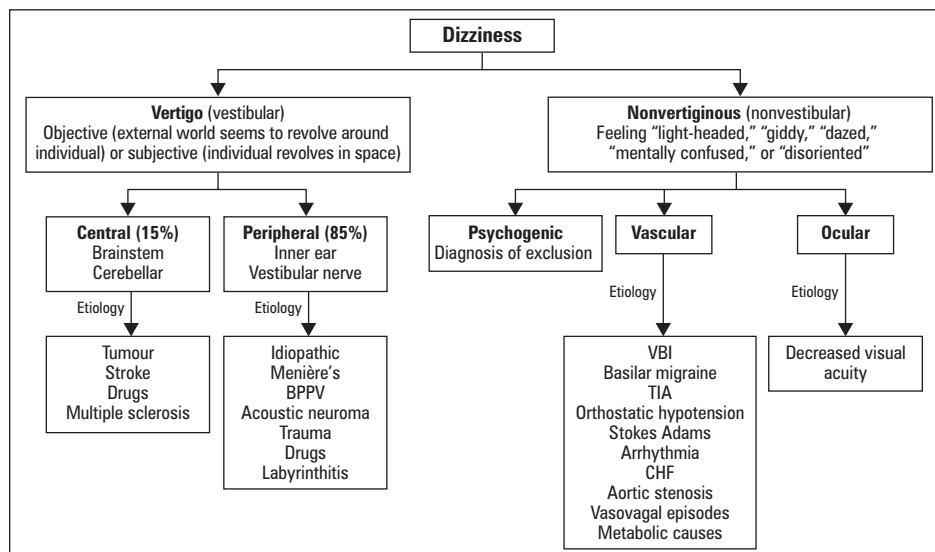

Figure 8. Differential Diagnosis of Dizziness

History

- clarify type of dizziness: vertigo, pre-syncope, dysequilibrium, light-headedness
- onset, precipitating/alleviating factors, preceding infections and activities, associated symptoms, previous experiences of dizziness
- duration (seconds to minutes vs. hours vs. days to weeks vs. persistent)
- exacerbations
 - worse with head movement or eye closure (vestibular)
 - no change with head movement and eye closure (nonvestibular)
 - worse with exercise (cardiac/pulmonary causes)

- associated symptoms
 - neurologic (central)
 - ♦ transient diplopia, dysphagia, dysarthria, ataxia (TIA, VBI, migraine)
 - ♦ persistent sensory and/or motor deficits (CNS)
 - audiologic (peripheral)
 - ♦ hearing loss, tinnitus, otalgia, aural fullness, recruitment
 - others
 - ♦ nausea, vomiting (peripheral vestibular disorders)
 - ♦ SOB, palpitations (hyperventilation, cardiac problem)
- general medical history
 - HTN, diabetes, heart disease, fainting spells, seizures, cerebrovascular disease, migraines
 - ototoxic drugs: aminoglycosides (gentamicin, streptomycin, tobramycin), erythromycin, ASA, antimalarials
 - hypotension (secondary to diuresis): furosemide, caffeine, alcohol

Dix-Hallpike Test

- Have the patient seated with legs extended and head at 45° rotation
- Rapidly shift patient to supine position with head fully supported in slight extension (for 45 seconds)
- Observe for rotatory nystagmus and ask about sensation of vertigo

Screening Instruments for Domestic Violence

A) WAST-SHORT

1. In general how would you describe your relationship?
 - a. Lot of tension
 - b. Some tension
 - c. No tension
2. Do you and your partner work out arguments with . . . ?
 - a. Great difficulty
 - b. Some difficulty
 - c. No difficulty

Endorsing either question 1 ("a lot of tension") or question 2 ("great difficulty") makes intimate partner violence exposure likely

B) HITS

- How often does your partner:
1. Physically Hurt you?
 2. Insult you?
 3. Threaten you with harm?
 4. Scream or curse at you?

Each question on HITS to be answered on a 5 point scale ranging from 1 (= never) to 5 (= frequently)
A total score of 10.5 is significant

How to Document Abuse

- Take photographs (with permission) of known or suspected injuries
- Use an injury location chart or "body map" when documenting physical findings
- Document any investigations ordered (e.g. x-ray)
- Write legibly or use a computer
- Record the patient's own words in quotation marks
- Avoid phrases that imply doubt about the patient's reliability (e.g. "patient claims that...")
- Record the patient's demeanor (e.g. upset, agitated)
- Record the time of day the patient is examined and how much time has elapsed since the abuse occurred

Physical Exam/Investigations

- syncopal
 - cardiac, peripheral vascular, and neurologic exams
 - bloodwork, ECG, 24-hr Holter, treadmill stress test, loop ECG, tilt table testing, carotid and vertebral doppler, EEG
- vertiginous
 - ENT and neurologic exams
 - Dix-Hallpike, consider audiometry and MRI if indicated
- non-syncopal, non-vertiginous
 - cardiac and neurologic exams
 - 3-minute hyperventilation trial, ECG, EEG

Treatment

- guided by history, physical and investigations
- include education, lifestyle modification, physical maneuvers (e.g. Epley for BPPV), symptomatic management (e.g. antiemetics), pharmacotherapy and surgery
- refer when significant central disease suspected, vertigo of peripheral origin is persistent (lasting >2-4 weeks), or if atypical presentation

Domestic Violence/Elder Abuse

INTIMATE PARTNER VIOLENCE

Definition

- includes physical, sexual, emotional, psychological and financial abuse (see Emergency Medicine, ER28)

Epidemiology

- lifetime prevalence of intimate partner violence against women is between 25% to 30%
- women who experience abuse have increased rates of injury, death and health consequences including 50-70% increase in gynecological, central nervous system, stress-related problems
- occurs in all socioeconomic, educational and cultural groups with increased incidence in pregnancy, disabled women, and 18-24 age group
- 25-50% chance of child abuse or neglect in families where abuse occurs
- physician recognition rates as low as 5%

Presentation

- multiple visits with vague, ill-defined complaints such as: headaches, gastrointestinal symptoms, insomnia, chronic pain, hyperventilation
- may also present with injuries inconsistent with history

Management

- screen ALL patients
 - always have a high index of suspicion
 - physician is often first person to get disclosure
 - health care visits are an important opportunity for physicians to address intimate partner violence
 - asking about abuse is the strongest predictor of disclosure
 - several screening tools (see sidebar) exist to identify victims of partner violence
 - make sure to determine the victim's level of immediate and long term danger and ask if there are weapons in the house

- ensure patient safety
 - victim most at risk for homicide when attempting to leave home or following separation
- provide community resources
 - safety planning includes ensuring that there is access to an exit in the home, establishing a safe place to go and having money, clothes, keys, medications, important documents and other emergency items prepared should the patient need to leave quickly
 - shelter or helpline number with legal advocacy and counselling services
 - involve social workers or domestic violence advocates
 - marital counselling inappropriate until safety is established and violence under control
- appointment for follow-up to assess whether condition is better or worse
- reassure patient she/he is not to blame and that the assault is a crime
 - goal is to convey the message that “As your doctor, I am concerned for your safety” and “Your partner has a problem that he/she needs help with” and “I want to help you”
 - reporting suspected or known child abuse is mandatory (see [Emergency Medicine](#), ER60)
 - spousal abuse is a criminal act, but not reportable without the woman's/man's permission
- DOCUMENT all evidence of abuse related visits for medico-legal purposes

ELDER ABUSE

Definition

- mistreatment of older people by those in a position of trust, power, or responsibility for their care
- types of abuse:
 - psychological (e.g. threatening, intimidating, insulting, demeaning, withholding information that may be important to them, ignoring)
 - financial (e.g. stealing, pressuring to sell or share home, misusing power of attorney)
 - physical (e.g. hitting, burning, locking in room, inappropriate use of physical restraints, withholding or misusing medication)
 - sexual
 - neglect

Risk Factors

- Female
- Older age (age 80 and older)
- Physical and mental frailty

Epidemiology

- 7% of adults in Canada age >65 reported experiences of emotional or financial abuse
- older adults who live with someone are more likely to be abused than those who live alone
- 2/3 of reported abuse cases involved family members, most often adult children followed by spouses
- older females are more likely to be abused than older males
- men are more likely than women to be victimized by an adult child (45% vs. 35%)
- women are more likely than men to experience violence at the hands of a spouse (30% vs. 19%) (Statistics Canada, 2004)
- reasons for under-reporting: fear, shame, cognitive impairment, language/cultural barriers, and social and geographic isolation

Screening

- insufficient evidence to include or exclude as part of the periodic health examination, but recommended that physicians be alert for indicators of abuse and institute measures to prevent further abuse
- general questions such as “Do you feel safe at home?” and move into more specific questions about different kinds of abuse

Presentation

- signs that an older adult is being abused may include:
 - depression, fear, anxiety, passivity, unexplained injuries, dehydration, malnutrition, poor hygiene, rashes, pressure sores, and over-sedation/inappropriate medication use

Management

- gather information from all sources (e.g. family members, health care providers, neighbours)
- perform a thorough physical examination
- ensure immediate safety and devise a plan for follow-up
- additional steps depend on whether the patient accepts intervention and whether they are capable of making decisions about their care
- interventions may include use of protective and legal services, senior resource nurses, elder abuse intervention teams and senior support groups

Dyspepsia

- see [Gastroenterology](#), G6

Definition and Clinical Features

- defined as epigastric pain or discomfort
- can be associated with fullness, belching, bloating, heartburn, food intolerance, nausea or vomiting

Epidemiology

- annual incidence 1-2%, prevalence 20-40%

Etiology

- common: functional, peptic ulcer disease, gastroesophageal reflux disease, gastritis
- others: cholelithiasis, irritable bowel disease, esophageal or gastric cancer, pancreatitis, pancreatic cancer, Zollinger-Ellison syndrome, and abdominal angina

History

- symptoms may not be useful in finding cause
- association with food, anorexia, nausea, vomiting, NSAID use
- symptoms suggestive of underlying pathology: weight loss, dysphagia, persistent vomiting, gastrointestinal bleeding (hematemesis, hematochezia)

Investigations and Management

- empiric therapy: H₂ receptor blockers, proton pump inhibitors
- testing for *H. pylori*: serology, urea breath test
- upper endoscopy (preferred), upper GI series

Dyspnea

- see [Respirology](#), R2 and [Emergency Medicine](#), ER27

History and Physical

- cough, sputum, hemoptysis, wheezing, chest pain, palpitations, dizziness, edema
- asthma, allergy, eczema, ASA/NSAID sensitivity, nasal polyps
- constitutional symptoms
- smoking, recreational drugs, medications
- occupational exposure, environmental exposure (e.g. pets, allergens, smoke)
- travel and birth place
- FHx of atopy
- previous CXR or PFTs
- exam: vitals, respiratory, precordial, HEENT, signs of anemia/liver failure/heart failure

Investigations

- CXR, ECG
- PFTs, ABG acutely if indicated

Management

- ABC's: send to Emergency Department if in severe respiratory distress
- depends on cause

Dysuria

- see [Urology](#), U4

Definition

- the sensation of pain, burning or discomfort on urination

Epidemiology

- in adulthood, more common in women than men
- approximately 25% of women report one episode of acute dysuria per year
- most common in women 25-54 years of age and in those who are sexually active
- in men, dysuria becomes more prevalent with increasing age

Etiology

- infectious
 - most common cause
 - presents as cystitis, urethritis, pyelonephritis, vaginitis or prostatitis
- non-infectious
 - hormonal conditions (postmenopausal hypoestrogenism), obstruction (BPH, urethral strictures), neoplasms, allergic reactions, chemicals, foreign bodies, trauma

DDX of Dyspnea

- Pulmonary embolism
- Deconditioning
- Foreign body aspiration
- DKA
- Anemia
- Asthma
- Pneumothorax

Risk Factors for Complicated Urinary Tract Infection

- Male sex
- Pregnancy
- Recent urinary tract instrumentation
- Functional or anatomic abnormality of the urinary tract
- Chronic renal disease
- Diabetes
- Immunosuppression
- Indwelling catheter

Table 20. Etiology, Signs and Symptoms of Dysuria

Infection	Etiology	Signs and Symptoms
UTI/Cystitis	<i>E. coli</i> , <i>S. saprophyticus</i> , <i>Proteus mirabilis</i> , <i>Enterobacter</i> , <i>Klebsiella</i> , <i>Pseudomonas</i>	Internal dysuria throughout micturition, frequency, urgency, incontinence, hematuria, nocturia, back pain, suprapubic discomfort, low grade fever (rare)
Urethritis	<i>C. trachomatis</i> , <i>N. gonorrhea</i> , <i>Trichomonas</i> , <i>Candida</i> , herpes	Initial dysuria, urethral/vaginal discharge, history of STI
Vaginitis	<i>Candida</i> , <i>Gardnerella</i> , <i>Trichomonas</i> , <i>C. trachomatis</i> , atrophic, herpes, lichen sclerosis	External dysuria/pain, vaginal discharge, irritation, dyspareunia, abnormal vaginal bleeding
Prostatitis	<i>E. coli</i> , <i>C. trachomatis</i> , <i>S. saprophyticus</i> , <i>Proteus mirabilis</i> , <i>Enterobacter</i> , <i>Klebsiella</i> , <i>Pseudomonas</i>	Dysuria, fever, chills, urgency, frequency, tender prostate
Pyelonephritis	<i>E. coli</i> , <i>S. saprophyticus</i> , <i>Proteus mirabilis</i> , <i>Enterobacter</i> , <i>Klebsiella</i> , <i>Pseudomonas</i>	Internal dysuria, fever, chills, flank pain radiating to groin, CVA tenderness, nausea or vomiting

Investigations

- no investigations necessary when history and physical consistent with uncomplicated UTI – treat empirically (urinalysis can be performed when indicated by dipstick or microscopy)
- radiologic studies and other diagnostic tests if atypical presentation
- urinalysis/urine R&M: pyuria, bacteriuria, hematuria
- urine C&S
- if vaginal/urethral discharge present: wet mount, Gram stain, KOH test, vaginal pH, culture for yeast and *Trichomonas*
- endocervical or urethral swab for *N. gonorrhea* and *C. trachomatis*
- renal U/S ± voiding cystourethrogram (VCUG) in children with recurrent UTI

Management

- UTI/cystitis
 - pregnant women with bacteriuria (2-7%) must be treated even if asymptomatic, due to risk of preterm labour; need to follow with monthly urine cultures and retreat if still infected
 - patients with recurrent UTIs (>3 per year), should be considered for prophylactic antibiotics
 - if complicated UTI, patients require longer courses of broader spectrum antibiotics
- urethritis
 - when swab is positive for chlamydia or gonorrhea must report to Public Health
 - all patients should return 4-7 days after completion of therapy for clinical evaluation

Does this Woman have an Acute Uncomplicated Urinary Tract Infection?

JAMA 2002; 287:2701-2710

Purpose: To review the accuracy and precision of history taking and physical examination for diagnosing UTI in women.

Study Characteristics: Systematic review of 9 studies looking at the accuracy or precision of history or physical examination in diagnosing uncomplicated UTI.

Participants: Healthy women. Infants, children or adolescents, pregnant women, nursing home patients, and patients with complicated UTI were excluded.

Main Outcomes: Precision and accuracy of history taking and physical exam.

Results: No studies examined precision as an outcome. Four symptoms and one sign significantly increased the probability of UTI: dysuria, frequency, hematuria, back pain, and CVA tenderness. Four symptoms and one sign significantly decreased the probability of UTI: absence of dysuria, absence of back pain, a history of vaginal discharge, a history of vaginal irritation, and vaginal discharge on examination.

Conclusions: Women who present with 1 or more symptoms of UTI have a probability of infection approaching 50%, effectively ruling in infection. Additional historical elements, physical examination, and urinalysis is unable to lower the post-test probability of UTI to a level where it can be ruled out. Additional testing, such as culture, should be pursued.

Prevention of UTIs

- Maintain good hydration (especially with cranberry juice)
- Wipe urethra from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse

Epistaxis

- see Otolaryngology, OT27

Table 21. Characteristics of Anterior vs. Posterior Bleeds

	Anterior (90%)	Posterior (10%)
Location/ Origin	Little's Area/Kiesselbach's Plexus	Woodruff's Plexus/Sphenopalatine Artery
Age	2-10, 50-80	Usually >50
Common Cause	Trauma (digital, fracture, foreign body), dry air, cool climate, post URTI, nasal dryness, chemical (nasal sprays, cocaine), tumour	Systemic: hepatic disease, primary/secondary bleeding disorder, medications (ASA, NSAIDs, warfarin), HTN, atherosclerosis
Treatment	Conservative: <ul style="list-style-type: none"> Position: upright leaning forward with direct digital pressure over soft part of nostril for >10 min ("pinch" up to cartilage) Humidifier in bedroom, nasal saline sprays, bacitracin or Vaseline® application to Little's area Silver nitrate Gelfoam/Hemostat Nasal packing with Vaseline® gauze, nasal catheter or sponge Cotton soaked in vasoconstrictor (oxymetazoline 0.5%) and topical anesthetic (4% lidocaine) placed in anterior nasal cavity with direct pressure for >10 min Investigations: CBC, Hct, cross & type, INR, PTT (only if severe), CT/nasopharyngoscopy if suspected tumour 	Emergency: ENT/ER consult for posterior packing with an intranasal balloon/Foley catheter Embolization/surgery
Prognosis	Usually stops with >10 min of pressure to nose	Copious bleed, often swallowed and vomited May lead to hypovolemic shock if not treated promptly

Erectile Dysfunction (ED)

- see Urology, U30

Definition

- consistent or recurrent inability to attain and/or maintain penile erection sufficient for sexual performance of ≥ 3 months duration

Epidemiology

- ~20% of men aged 40; ~50% of men aged 70

Etiology

- organic: vascular (90%) (arterial insufficiency, atherosclerosis), endocrine (low testosterone, diabetes), anatomic (structural abnormality e.g. Peyronie's), neurologic (post-op, DM), medications (clonidine, antihypertensives, psychotropics)
- psychogenic (10%)

Table 22. Differentiation Between Organic and Psychogenic Erectile Dysfunction

Characteristic	Organic	Psychogenic
Onset	Gradual	Acute
Circumstances	Global	Situational
Course	Constant	Varying
Non-coital erection	Poor	Rigid
Psychosexual problem	Secondary	Long history
Partner problem	Secondary	At onset
Anxiety and fear	Secondary	Primary

Walsh: Campbell's Urology, 8th ed. Table 46-4.

History

- comprehensive sexual, medical and psychosocial history
- time course
 - last satisfactory erection
 - gradual or sudden onset
 - attempts at sexual activity
- quantify
 - presence of morning or night time erections
 - stiffness (scale of 1-10)
 - ability to initiate and maintain an erection with sexual stimulation
 - erection stiffness during sex (scale of 1-10)
- qualify
 - partner or situation specific
 - loss of erection before penetration or climax
 - degree of concentration required to maintain an erection
 - percentage of sexual attempts satisfactory to patient and/or his partner
 - significant bends in penis or pain with erection
 - difficulty with specific positions
 - impact on quality of life and relationship

Investigations

- hypothalamic-pituitary-gonadal axis evaluation: testosterone (free + total), prolactin, LH
- risk factor evaluation: fasting glucose, HbA1c, lipid profile
- others: TSH, CBC, urinalysis
- specialized testing
 - psychological and/or psychiatric consultation
 - in-depth psychosexual and relationship evaluation
 - nocturnal penile tumescence and rigidity (NPTR) assessment
 - vascular diagnostics (e.g. doppler studies, angiography)

Management

Table 23. Management of Erectile Dysfunction

Nonpharmacologic	Pharmacologic	Surgical
Lifestyle changes (alcohol, smoking, exercise)	Oral agents	Implants
Relationship/sexual counselling	Suppository (MUSE: male urethral suppository for erection)	Vascular repair
Vacuum devices	Injections	Realignment

Modifiable Risk Factors and Erectile

Dysfunction: Can Lifestyle Changes Modify Risk?
Urology 2000; 56:302-306

Study: A prospective cohort study designed to examine whether changes in smoking, heavy alcohol consumption, sedentary lifestyle, and obesity are associated with the risk of ED in men aged 40-70.

Results: Obesity was associated with ED ($P=0.006$), with baseline obesity conferring higher risk regardless of subsequent weight loss. Level of physical activity was associated with ED ($P=0.01$): those initiating physical activity or remaining active had a lower risk of ED, while those who remained sedentary had a higher risk. As compared to their sedentary peers, those who initiated exercise in midlife had a 70% reduced ED rate. Changes in smoking or alcohol intake were not associated with ED ($P>0.3$).

Conclusion: Although making lifestyle changes in midlife may be too late to reverse the effects of smoking, obesity, and alcohol consumption on ED, initiating physical activity in midlife may in fact reduce ED relative to peers who remain sedentary. Adopting a healthy lifestyle early in life may be the best approach to reducing the risk of developing ED in later years.

- pharmacologic treatment
 - phosphodiesterase type 5 inhibitors (see Table 24)
 - alpha adrenergic blockers (e.g. yohimbine)
 - serotonin antagonist and reuptake inhibitor (e.g. trazodone)
 - testosterone – currently only indicated in patients presenting with hypogonadism and testosterone deficiency (note: breast/prostate cancer are absolute contraindications)

Table 24. Phosphodiesterase Type 5 Inhibitors

Examples	Dosing (1 dose/day)	Specifics	Side Effects	Contraindications
sildenafil (Viagra®)	25-100 mg/dose	Take 0.5-4 hr prior to intercourse May last 24 hours	Flushing, headache, indigestion	Not to be used in patients taking nitrates
tadalafil (Cialis®)	5-20 mg/dose	Effects may last 36 hours	As above	As above
varafenafil (Levitra®)	2.5-20 mg/dose	Take 1 hr prior to intercourse	As above	As above

Fatigue

Epidemiology

- 25% of office visits to family physicians
 - peaks in ages 20-40
 - women 3-4x > men
- 50% have associated psychological complaints/problems, especially if <6 month duration

Differential Diagnosis

Table 25. Differential Diagnosis of Fatigue: PS VINDICATE

P	Psychogenic	Depression, sleep disorder, life stresses , anxiety disorder, chronic fatigue syndrome, fibromyalgia
S	Sedentary	Unhealthy/sedentary lifestyle
V	Vascular	Stroke
I	Infectious	Viral (e.g. mononucleosis, hepatitis), bacterial (e.g. TB), fungal, parasitic, HIV
N	Neoplastic	Any malignancy
	Nutrition	Anemia (Fe deficiency, B ₁₂ deficiency)
	Neurogenic	Myasthenia gravis, multiple sclerosis, Parkinson's Disease
D	Drugs	Beta-blockers, antihistamines, anticholinergics, benzodiazepines, antiepileptics
I	Idiopathic	
C	Chronic illnesses	CHF, lung diseases (e.g. COPD, sarcoidosis), renal failure, chronic liver disease
A	Autoimmune	SLE, RA, mixed connective tissue disease, polymyalgia rheumatica
T	Toxin	Substance abuse (e.g. alcohol), heavy metal
E	Endocrine	Hypothyroidism, diabetes , Cushing's syndrome, adrenal insufficiency, pregnancy

Common causes are in **bold**.

Investigations

- psychosocial causes are common, so usually minimal investigation is warranted
- physical causes of fatigue usually have associated symptoms/signs that can be elicited from a focused history and physical examination
- investigations should be guided by history and physical and may include:
 - CBC + differential, electrolytes, BUN, Cr, ESR, glucose, TSH, ferritin, vit B₁₂, total protein, albumin, AST, ALT, ALP, bilirubin, calcium, phosphate, ANA, beta-hCG
 - urinalysis, CXR, ECG
 - additional tests: serologies (Lyme disease, hepatitis B and C screen, HIV, ANA) and PPD skin tests

Treatment

- treat the cause
- if etiology undetermined (underlying cause cannot be identified in 1/3 of patients)
 - reassurance and follow-up, especially with fatigue of psychogenic etiology
 - supportive counselling, behavioural, or group therapy
 - encourage patient to stay physically active to maximize function
 - review all medications, OTC, and herbal remedies for drug-drug interactions and side effects
 - prognosis: after 1 year, 40% are no longer fatigued

Fatigue Red Flags

Fever
Weight loss
Night sweats
Neurological deficits
Ill-appearing

CHRONIC FATIGUE SYNDROME (CFS)

Definition (CDC 2006) – must meet both criteria

1. new or definite onset of unexplained, clinically evaluated, persistent or relapsing chronic fatigue, not relieved by rest, which results in occupational, educational, social, or personal dysfunction
 2. concurrent presence of at least 4 of the following symptoms for a minimum of 6 months:
 - impairment of short-term memory or concentration, severe enough to cause significant decline in function
 - sore throat
 - tender cervical or axillary lymph nodes
 - muscle pain
 - multi-joint pain with no swelling or redness
 - new headache
 - unrefreshing sleep
 - post-exertion malaise lasting >24 hours
- exclusion criteria: medical conditions that may explain the fatigue, certain psychiatric disorders (depression with psychotic or melancholic features, schizophrenia, eating disorders), substance abuse, severe obesity (BMI >45)

Exercise Therapy for Chronic Fatigue

Cochrane Depression, Anxiety, and Neurosis Group.
Cochrane Database of Systematic Reviews 2004;
Issue 3

Purpose: To determine the effectiveness of exercise therapy for Chronic Fatigue Syndrome (CFS).

Methods: Systematic review of 5 RCTs with 336 patients of all ages with a clinical diagnosis of CFS.

Interventions: Exercise therapy alone was compared with treatment as usual (or relaxation and flexibility), pharmacotherapy (fluoxetine), or exercise therapy combined with either pharmacotherapy or patient education.

Results: At 12 weeks, patients undergoing exercise therapy were less fatigued than controls (SMD -0.77; 95% CI, -1.26 to -0.28). Physical functioning was also significantly improved, but there were more dropouts with exercise therapy. Compared with fluoxetine, patients receiving exercise therapy were less fatigued (WMD -1.24; 95% CI, -5.31 to 2.83). Patients receiving combination therapy with exercise therapy and either fluoxetine or patient education, did better than those on monotherapy.

Conclusions: Patients may benefit from exercise therapy. Combination therapy with either fluoxetine or education may offer additional benefit. Further high quality trials are needed.

Epidemiology

- F>>M, Caucasians > other groups, majority in their 30s
- CFS found in <5% of patients presenting with fatigue

Etiology

- unknown, likely multifactorial
- may include infectious agents, immunological factors, neurohormonal factors, and/or nutritional deficiency

Investigations

- no specific laboratory tests diagnose CFS

Treatment

- promote sleep hygiene
- provide support and reassurance that most patients improve over time
- non-pharmacological
 - regular physical activity
 - optimal diet
 - psychotherapy (e.g. CBT), family therapy, support groups
- pharmacological
 - to relieve symptoms: e.g. antidepressants, anxiolytics, NSAIDs, antimicrobials, antiallergy therapy, antihypertensive therapy (increase dietary sodium, fludrocortisone)

Fever

Differential Diagnosis

Table 26. Differential Diagnosis of Fever

Infection	Cancer	Medications		Other
Bacterial	Leukemia	Allopurinol	Nifedipine	Irritable Bowel Disease
Viral	Lymphoma	Captopril	Phenytoin	Collagen-vascular disease
TB	Other Malignancies	Cimetidine	Diuretics	DVT
		Heparin	Barbiturates	
		INH	Antihistamines	
		Meperidine		

Definition

- mean oral temperature = 36.8°C, unadjusted TM temperature is 0.4°C lower, rectal temperature usually 0.4°C higher
- diurnal variation: usually 0.5°C higher at 4PM vs. 6AM
- fever = oral temperature >37.2°C (AM), 37.7°C (PM)

History

- fever
 - peak temperature, thermometer, route
 - time of day
 - response to antipyretics
- systemic symptoms
 - weight loss, fatigue, rash, arthralgia

- symptoms of possible source
 - UTI/pyelonephritis: dysuria, foul-smelling urine, incontinence, frequency, hematuria, flank pain
 - pneumonia: cough, pleuritic chest pain
 - URTI: cough, coryza, ear pain
 - meningitis: headache, confusion, stiff neck, rash
 - osteomyelitis: bone pain
 - skin: purulent discharge
 - PID: discharge, dyspareunia
 - gastroenteritis: abdominal pain, diarrhea, blood per rectum, vomit
 - medications
 - DVT: swollen legs, pain in calf, shortness of breath, pleuritic chest pain
 - history of cancer/family history of cancer
- infectious contacts
 - travel history, camping, daycare, contact with TB, foodborne, animals

Investigations

- CBC & differential, blood culture, urine culture, urinalysis
- stool O&P, Gram stain, culture
- CXR, TB skin test, sputum culture
- LP

Management

- general: sponge bath, light clothing
- acetaminophen/ibuprofen as needed
- treat underlying cause

Joint Pain

- see [Rheumatology](#), RH3

Differential Diagnosis

Table 27. Differential Diagnosis of Joint Pain

Non-Articular		Articular	
Localized	Generalized	Inflammatory	Degenerative
Bursitis Tendonitis Capsulitis	Fibromyalgia Polymyalgia rheumatica	Seropositive <ul style="list-style-type: none"> • Rheumatoid arthritis • Systemic lupus erythematosus • Scleroderma • Polymyositis • Sjogren's syndrome Seronegative <ul style="list-style-type: none"> • Ankylosing spondylitis • Inflammatory bowel disease • Psoriatic arthritis • Reactive arthritis Crystal <ul style="list-style-type: none"> • Gout • Pseudogout • Milwaukee shoulder, calcific periarthritis Infectious <ul style="list-style-type: none"> • Gonococcal • Non-gonococcal 	Primary <ul style="list-style-type: none"> • Familial Heberden's node • Inflammatory osteoarthritis • Regional hip or knee Secondary <ul style="list-style-type: none"> • Metabolic • Hemophiliac • Neuropathic • Traumatic

History

- number of joints involved – monoarticular, oligoarticular, polyarticular
- pattern of joints involved – symmetrical vs. asymmetrical, large vs. small joints, axial skeleton
- relation to activity (inflammatory better with activity, degenerative worse)
- relation to rest (inflammatory worse with rest, degenerative better)
- morning stiffness >30 minutes (inflammatory)
- soft tissue swelling, erythema (inflammatory)
- onset – acute vs. chronic (>6 weeks)
- trauma, infection, medications (steroids, diuretics)
- FHx of arthritis
- co-morbidities: diabetes mellitus (carpal tunnel syndrome), renal insufficiency (gout), psoriasis (psoriatic arthritis), myeloma (low back pain), osteoporosis (fracture), obesity (OA)
- constitutional symptoms (neoplasm)

- systemic features
 - fever (SLE, infection)
 - rash (SLE, psoriatic arthritis)
 - nail abnormalities (psoriatic, reactive arthritis)
 - myalgias (fibromyalgia, myopathy)
 - weakness (polymyositis, neuropathy)
 - GI symptoms (scleroderma, IBD)
 - GU symptoms (reactive arthritis, gonococemia)

Physical Exam

- vitals
- specific joint exams
- systemic features (skin, nails, eyes, hands)

Investigations

- CBC + differential, ESR, CRP, RF, ANA, HLA-B27, serum uric acid, calcium
- urinalysis
- tissue cultures
- x-ray
- joint aspirate for cell count + differential, culture, Gram stain, microscopy

Headache

- see [Neurology](#), N39

Primary Headaches

Table 28. Primary Headaches

	Migraine	Tension-type	Cluster	Caffeine Withdrawal
Epidemiology	12% of adults F>M 20% with aura 80% without aura	38% of adults, can be episodic or chronic	<0.1% of adults, M>>F	~50% of people drinking >2.5 cups/d
Duration	5-72 hrs	May occur as isolated incident or daily, duration is variable	<3 hrs at same time of day	Begins 12-24 hrs after last caffeine intake, can last ~1 wk
Pain	Classically unilateral and pulsatile, but 40% are bilateral, moderate-severe intensity, nausea/vomiting, photo/phonophobia	Mild to moderate pain, bilateral, fronto-occipital or generalized pain, band-like pain, ± contracted neck/scalp muscles, associated with little disability	Sudden, unilateral, severe, usually centered around eye, frequently awakens patient	Severe, throbbing, associated with drowsiness, anxiety, muscle stiffness, nausea, waves of hot or cold sensations
Triggers	Numerous (e.g. food, sleep disturbance, stress, hormonal, fatigue, weather, high altitude) Aggravated by physical activity	Stressful events, NOT aggravated by physical activity	Often alcohol	Discontinuing caffeine
Treatment of Acute Headache	1 st line: acetaminophen, ASA, ± caffeine 2 nd line: NSAIDs 3 rd line: 5HT agonists ± antiemetic	Rest and relaxation NSAIDs	Sumatriptan Dihydroergotamine High-flow O ₂ Intranasal lidocaine	Caffeine Acetaminophen or ASA ± caffeine
Prophylactic Therapy	1 st line: beta-blockers 2 nd line: TCAs 3 rd line: anticonvulsants	Rest and relaxation, physical activity, biofeedback	Lithium carbonate, prednisone, methysergide	Cut down on caffeine

Headache Red Flags

Sudden onset of severe headache
Worst headache ever
New headache after age 50
Headache present on awakening
Impaired mental status
Fever
Neck stiffness
Seizures
Focal neurologic deficits
Jaw claudication
Scalp tenderness
Worse with exercise, sexual activity orValsalva

Secondary Headaches

- caused by underlying organic disease
- account for <10% of all headaches, may be life-threatening
- etiology
 - space-occupying lesion
 - systemic infection (meningitis, encephalitis)
 - stroke
 - subarachnoid hemorrhage
 - systemic disorders (thyroid disease, hypertension, pheochromocytoma, etc.)
 - temporal arteritis
 - traumatic head injuries
 - TMJ or C-spine pathology
 - serious ophthalmological and otolaryngological causes of headache

- treatment
 - based on underlying disorder
 - analgesics may provide symptomatic relief

Investigations

- indicated only when red flags are present and may include:
 - CBC for suspected systemic or intracranial infection
 - ESR for suspected temporal arteritis
 - neuroimaging (CT or MRI) to rule out intracranial pathology
 - CSF analysis for suspected hemorrhage, infection, tumour or disorders related to CSF

Hearing Impairment

- see Otolaryngology, OT9

Definition

- hearing impairment: a raised hearing threshold measured as decibels of hearing loss relative to the normal population at specific frequencies
- hearing disability: hearing impairment that interferes with performing daily tasks

Epidemiology

- 10% of the population is hard of hearing or deaf
- 90% of age-related hearing loss (presbycusis) is sensorineural
- hearing loss detectable by audiology is present in greater than 1/3 of people over 65
- associated with significant physical, functional and mental health consequences

Classification

- conductive (sound does not reach cochlea)
- sensorineural (sound is not converted or transmitted via neural signals)
- mixed

Assessment

- infants
 - universal newborn hearing screening program
- elderly
 - whispered-voice test
 - ♦ whisper six test words 6 inches to 2 feet away from the patient's ear out of the visual field, ask patient to repeat the words (with non-test ear distraction)
 - tuning fork test
 - ♦ Rinne and Weber (not for general screening)
 - audioscope
 - ♦ delivers pure tone frequencies to obtain thresholds for frequencies of 250-8000 Hz

Management

- counsel about noise control and hearing protection programs (grade A evidence)
- refer patients with hearing loss for a complete audiological examination
- hearing amplification (e.g. hearing aids), assistive listening devices, and cochlear implants can dramatically improve quality of life

Does this Patient have Hearing Impairment?

JAMA 2006; 295:416-428

Purpose: To evaluate bedside clinical maneuvers used to evaluate the presence of hearing impairment.

Study: Evidence-based review of studies examining the accuracy or precision of screening questions and tests. 24 studies were included in this analysis.

Conclusions: Elderly patients who admit to having hearing impairment should be offered audiometry, while those who do not should undergo a whispered-voice test. Those who hear the whispered voice require no further testing, while those who do not require audiometry. The Weber and Rinne tests are not useful in screening for hearing impairment.

Hypertension

Epidemiology

- 20-25% of Canadian adults have HTN (and up to 50% undiagnosed)
- 16% have adequate BP control
- approximately 50% of adult Canadians are hypertensive by age 60
- 3rd leading risk factor associated with death
 - risk factor for CAD, CHF, cerebrovascular disease, renal failure, peripheral vascular disease

Definition

- hypertension
 - BP $\geq 140/90$ mmHg (see Figure 9)
- isolated systolic hypertension
 - sBP ≥ 140 and dBP < 90
 - associated with progressive reduction in vascular compliance
 - usually begins in 5th decade; up to 11% of 75 year olds

Symptoms of hypertension are usually **NOT PRESENT** (this is why it is called the "silent killer").

May have occipital headache upon awakening or organ specific complaints if advanced disease.

Hypertensive Emergencies

1. Accelerated malignant HTN with papilledema

2. Cerebrovascular:

Hypertensive encephalopathy
CVA with severe hypertension
Intracerebral hemorrhage
SAH

3. Cardiac:

Acute aortic dissection
Acute refractory LV failure
Acute MI with persistent ischemic pain after CABG

4. Renal:

Acute glomerulonephritis
Renal crises from collagen vascular diseases
Severe hypertension following renal transplantation

5. Excessive circulating catecholamines:

Pheochromocytoma
Tyramine containing foods or drug interactions with MAOIs
Sympathomimetic drug use (e.g. cocaine)
Rebound HTN after cessation of anti-hypertensive drugs (e.g. clonidine)

6. Eclampsia

7. Surgical:

Severe HTN prior to emergent surgery
Severe post-op HTN
Post-op bleeding from vascular suture lines

8. HTN following severe burns

9. Severe epistaxis

- accelerated hypertension
 - significant recent increase in BP over previous hypertensive levels associated with evidence of vascular damage on fundoscopy but without papilledema
- malignant hypertension
 - sufficient elevation in BP to cause papilledema and other manifestations of vascular damage (retinal hemorrhages, bulging discs, mental status changes, increasing creatinine)
 - not defined by absolute level of BP, but often requires BP of >200/140
 - develops in about 1% of hypertensive patients
- hypertensive urgency
 - sBP >210 or dBP >120 with minimal or no target-organ damage
- hypertensive emergency
 - high BP + acute target-organ damage

Etiology

- essential (primary) hypertension (>90%)
 - undetermined cause
- secondary hypertension (10%)
- watch for labile, “white coat” hypertension (office-induced elevated BP)

Predisposing Factors

- family history
- obesity (especially abdominal)
- alcohol consumption
- stress
- sedentary lifestyle
- smoking
- male gender
- age >30
- excessive salt intake/fatty diet
- African American ancestry
- dyslipidemia

Causes of Secondary Hypertension

ABCDE

Apnea, Aldosteronism
Bruits, Bad kidneys
Coarctation, Cushing's, Catecholamines,
Calcemia
Drugs
Endocrine disease

Table 29. Causes of Secondary Hypertension

Obstructive Sleep Apnea	Common cause		
Renal	Renovascular HTN Renal parenchymal disease, glomerulonephritis, pyelonephritis, polycystic kidney		
Endocrine	1° hyperaldosteronism Pheochromocytoma Cushing's syndrome Hyperthyroidism/hyperparathyroidism Hypercalcemia of any cause		
Vascular	Coarctation of the aorta Renal artery stenosis		
Drug-induced	Estrogens MAOIs Cocaine	Steroids Lithium Amphetamines	NSAIDs Decongestants Alcohol

Investigations

- for all patients with hypertension (D)
 - CBC, electrolytes, Cr, fasting glucose and lipid profile, 12-lead ECG, urinalysis
- for specific patient subgroups (D)
 - DM or renal disease: urinary protein excretion
 - increasing Cr OR history of renal disease or proteinuria OR HTN resistant to 3 meds OR presence of abdominal bruit: renal ultrasound, captopril renal scan, MRA/CTA (B)
 - if suspected endocrine cause: plasma aldosterone, plasma renin (D)
 - if suspected pheochromocytoma: 24h urine for metanephrines and creatinine (C)
 - echocardiogram for left ventricular dysfunction assessment if indicated (C)

Keys to Grade of Recommendations for Hypertension Diagnosis and Treatment

Grade

A	High levels of internal validity and statistical precision
B/C	Lower levels of internal validity and statistical precision
D	Expert opinion

Diagnosis

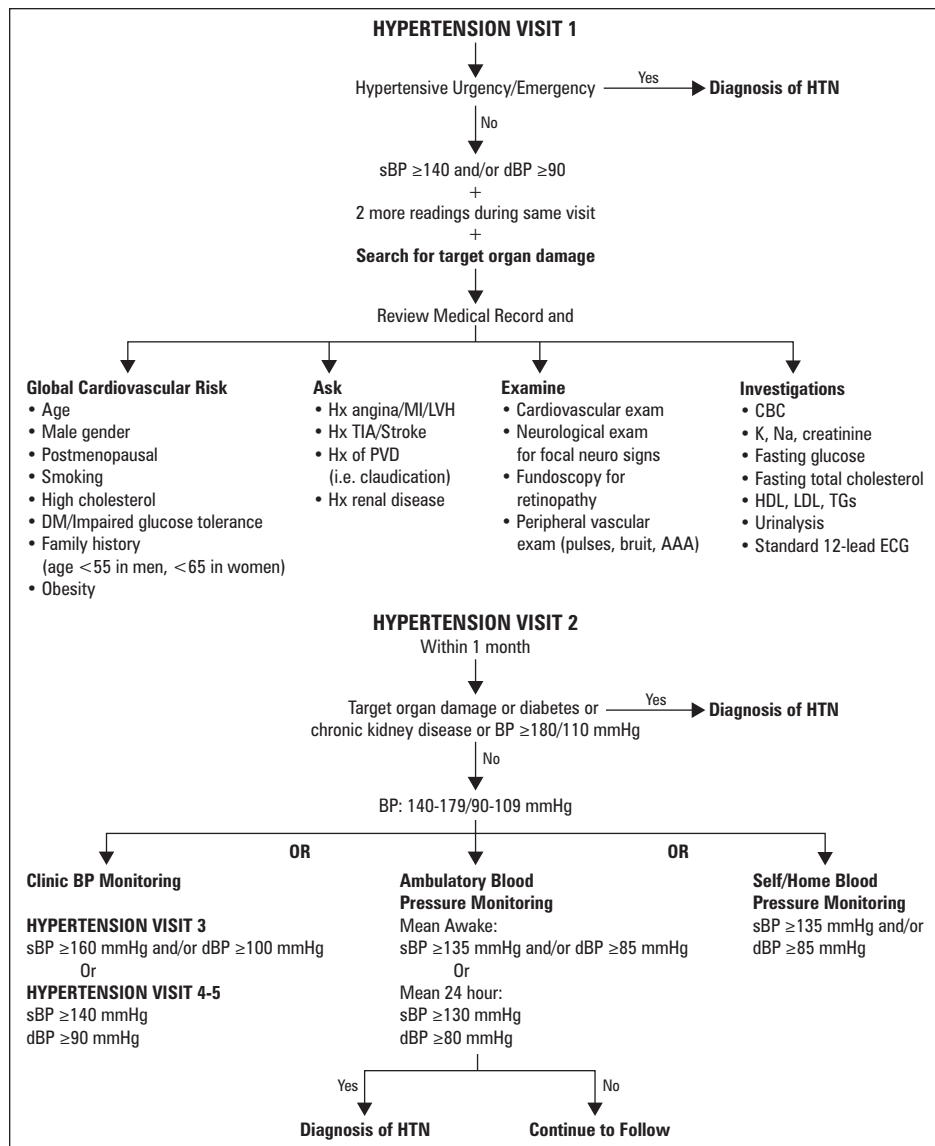

Figure 9. Approach to Hypertension

Adapted from: *The Canadian Journal of Cardiology* 2006;22(7):577.

Treatment

- target BP is <140/90 mmHg, <130/80 if DM or chronic kidney disease
- lifestyle modification (in all HTN patients)
 - may be sufficient in patients with stage 1 HTN (140-159/90-99)
 - diet
 - ♦ follow Canada's Guide to Healthy Eating (see *Nutrition*, FM4) and DASH (reduced cholesterol and saturated fats) (B)
 - ♦ limit daily sodium intake to 65-100 mmol (1.5-2.3 g) (B)
 - ♦ potassium/magnesium/calcium supplementations are NOT recommended for HTN (B)
 - moderate intensity dynamic exercise: 30-60 minutes, 4-7 x/week (D); higher intensity exercise is no more effective (D)
 - smoking cessation
 - low-risk alcohol consumption (see *Alcohol*, FM10) (B)
 - achieve and maintain a healthy BMI (18.5-24.9) and waist circumference (<102 cm for men, <88 cm for women) (C); BP will decrease by 4.0/2.8 mmHg for each 4.4 kg of weight loss; use multidisciplinary approach to weight loss (B)
 - individualized cognitive behavioural interventions for stress management (B)

The Effects of Lifestyle Modification on Diet, Weight, Physical Fitness and Blood Pressure Control. 18-month Follow-up Results from the PREMIER Collaborative Research Group

Ann Intern Med 2006; 144(7):127

Purpose: To compare effects of 2 lifestyle modification interventions compared to advice only on hypertension status, blood pressure, and lifestyle changes.

Study: Multicentre, randomized trial.

Patients: 810 adults with prehypertension or stage 1 hypertension (sBP 120-159, dBP 80-95)

Interventions: Multicomponent behavioural intervention using established recommendations ("established") arm, established recommendations plus the Dietary Approaches to Stop Hypertension (DASH) diet ("established + DASH") arm, and advice only arm.

Main outcomes: Lifestyle status and blood pressure.

Results: At 18 months, absolute blood pressures were reduced for both intervention arms compared to advice only but differences were non-significant. The odds for hypertension at 18 months were reduced for both treatment arms compared to advice only. Statistically significant weight loss, fat intake and sodium intake were noted for both treatment arms.

Dieting to Reduce Body Weight for Controlling Hypertension in Adults

Cochrane Database of Systemic Reviews 1998:

Issue 4

A systematic review of eighteen trials showed that weight-reducing diets in overweight hypertensive persons can affect modest weight loss in the range of 3-9% of body weight and are probably associated with modest blood pressure decreases of roughly 3 mmHg systolic and diastolic. Weight-reducing diets may decrease dosage requirements of persons taking antihypertensive medications.

Thiazides as First-Line Antihypertensive Therapy – ALLHAT

JAMA 2002; 288:2981-97

Study: Randomized, double-blind, active-controlled clinical trial with mean follow-up of 4.9 years.

Patients: 33,357 participants (mean age 67y, 53% male, 47% white) with stage 1 or 2 hypertension and at least one other CHD risk factor.

Intervention: Participants were randomly assigned to receive chlorthalidone (12.5-25mg/d), amlodipine (2.5-10mg/d), or lisinopril (10-40mg/d). Target BP was <140/90 mmHg, achieved by titrating the assigned study drug, and adding open-label agents when necessary.

Outcomes: The primary outcome was combined fatal CHD or non-fatal MI. Secondary outcomes were all-cause mortality, stroke, combined CHD, and combined CVD.

Results: There were no significant differences in either the primary outcome or all-cause mortality between treatment groups. For amlodipine vs. chlorthalidone, secondary outcomes were similar except for a higher 6-year rate of heart failure with amlodipine (10.2% vs. 7.7%; p<0.001). For lisinopril vs. chlorthalidone, lisinopril had higher 6-year rates of combined CVD (33.3% vs. 30.9%; p<0.001), stroke (6.3% vs. 5.6%; p=0.02) and heart failure (8.7% vs. 7.7%; p<0.001).

Conclusion: Thiazide-type diuretics are superior to CCB and ACEI for preventing one or more major forms of CVD, with similar risks of death and non-fatal MI.

**Calcium Channel Blockers****Dihydropyridine CCBs**

- amlodipine
- nifedipine
- felodipine

Non-dihydropyridine CCBs

- diltiazem
- verapamil

**How to Combine Antihypertensive Medications**

- pharmacological
 - indications regardless of age, be cautious with frail elderly patients
 - ♦ dBP ≥ 90 mmHg with target organ damage or independent cardiovascular risk factors (A)
 - ♦ dBP ≥ 100 mmHg (A) or sBP ≥ 160 mmHg (A) without target organ damage or cardiovascular risk factors
 - ♦ sBP ≥ 140 with target organ damage
- if partial response to standard dose monotherapy, add another first-line drug (C)
- caution with combination of non-DHP CCB and beta-blocker (D)
- combination of ACE inhibitor and ARB is not recommended (A)
- if still not controlled or adverse effects, can add other classes of anti-hypertensives (D)
- choice of therapy in patients with unique conditions (see Table 30)
- most patients will require combination therapy for optimal control

Follow-Up

- assess and encourage adherence to pharmacological and non-pharmacological therapy at every visit
- lifestyle modification \rightarrow q3-6 months
- pharmacological
 - q1-2 months until BP under target for 2 consecutive visits
 - more often for symptomatic HTN, severe HTN, antihypertensive drug intolerance, target organ damage
 - q3-6 months once at target BP
- referral is indicated for cases of refractory hypertension, suspected secondary cause or worsening renal failure
- hospitalization is indicated for malignant hypertension

Table 30. Pharmacologic Treatment of Hypertension in Patients with Unique Conditions

Condition or Risk Factor	Recommended Drugs	Alternative Drugs	Not Recommended
Isolated Diastolic HTN	Thiazide diuretic	β -blockers (age < 60) ACEI or ARB or CCB	α -blocker, β -blocker monotherapy (age > 60)
Isolated Systolic HTN	Monotherapy with low dose diuretics	Long acting dihydropyridine CCB or ARB	α -blocker, monotherapy with β -blockers
Ischemic Heart Disease (IHD)	ACEI	β -blockers or long-acting CCB if stable angina	Short-acting CCB (nifedipine) ACEI + ARB if no co-existing systolic heart failure
Recent STEMI or NSTEMI	β -blocker + ACEI	ARB (if intolerant to ACEI) Long-acting CCB if β -blocker is contraindicated or ineffective	Non-DHP CCB if evidence of heart failure
Left Ventricular Hypertrophy	Long-acting CCB, or thiazide diuretic		Direct arterial vasodilators: hydralazine, minoxidil
Cerebrovascular Disease (stroke/TIA)	ACEI + diuretic		ACEI + ARB after a stroke
Systolic Dysfunction	ACEI + β -blockers (diuretics as additive therapy) Aldosterone antagonists for NYHA Class III/IV or post-MI ACEI + ARB (uncontrolled HTN)	ARB (if intolerant to ACEI) Hydralazine + isosorbide dinitrate (if ACEI + ARB contraindicated) Long-acting CCB	Non-DHP CCB Carefully monitor for s/e if using ACEI + ARB
Dyslipidemias	As for uncomplicated IHD	As for uncomplicated IHD	β -blockers without ISA
Peripheral Vascular Disease	β -blockers (if severe disease)	As for uncomplicated IHD	As for uncomplicated IHD
Diabetes Mellitus with Nephropathy (urinary albumin ≥ 30 mg/d)	ACEI or ARB	Add other anti-hypertensives	α -blocker
Diabetes Mellitus without Nephropathy (ACR < 2.0 mg/mmol for men, < 2.8 for women)	ACEI, ARB, DHP CCB, or thiazide	Cardioselective β -blockers or non-DHP CCB Can add other first-line agents	If creatinine > 150 μ mol/L, use loop diuretic instead of thiazide diuretic ACEI + ARB if normal urine albumin
Non-diabetic Chronic Kidney Disease	ACEI (thiazide diuretics as additive therapy)	Can add thiazide diuretic Loop diuretics if volume overload	ACEI + ARB
Renovascular Disease	Same as HTN without other indications		Caution with ACEI or ARB due to risk of ARF
Asthma	K-sparing + thiazide diuretics for patients on salbutamol		β -blockers, unless specific indications like angina or post-MI
Gout			Thiazides, but asymptomatic hyperuricemia is not a contraindication

Table 30. Pharmacologic Treatment of Hypertension in Patients with Unique Conditions (continued)

Condition or Risk Factor	Recommended Drugs	Alternative Drugs	Not Recommended
Smoking	Low dose thiazides ACEI		β -blockers
Pregnancy	Methyldopa Hydralazine	Labetolol Nifedipine	ACEI
Elderly (>60)	As for uncomplicated IHD, except for use of β -blockers		β -blockers not recommended as first line treatment
Emergency	(BP > 169/90) = labetalol, nifedipine		
If > 3 cardiovascular RFs or established atherosclerotic disease	Statin, ASA		Caution with use of ASA in patients with uncontrolled BP

ISA = intrinsic sympathomimetic activity, ARB = angiotensin II receptor blockers, ACEI = angiotensin converting enzyme inhibitor

Adapted from: McAlister FA, Zarnke KB, Campbell NRC, et al. (2002). The 2001 Canadian recommendations for the management of hypertension: Part two – Therapy. *Can J Cardiol*, 18(6):625-641. AND The 2010 Canadian Hypertension Education Program Recommendations.

Low Back Pain

- see Orthopaedics, OR23

Definition

- acute: <6 weeks
- subacute: 6-12 weeks
- chronic: >12 weeks

Epidemiology

- 5th most common reason for visiting a physician
- lifetime prevalence: 90%
- peak prevalence: age 45-60
- largest WSIB category
- most common cause of chronic disability for persons <45 years old
- 90% resolve in 6 weeks, <5% become chronic

Etiology

- source of pain can be local, radicular, referred, or related to a psychiatric illness
- 98% mechanical cause
 - ligamentous/muscle strain, facet joint degeneration, disc injury, spondylosis, spondylolisthesis, compression fracture, spinal stenosis, pregnancy
 - worse with movement, improved with rest
- 2% non-mechanical cause
 - most concerning when pain is worse at rest and does not change with position
- surgical emergencies
 - cauda equina syndrome: low back pain, areflexia, lower extremity weakness, fecal incontinence, urinary retention, saddle anesthesia, decreased anal tone
 - abdominal aortic aneurysm: pulsatile abdominal mass
- medical conditions
 - neoplastic (primary, metastatic, multiple myeloma)
 - infectious (osteomyelitis, TB)
 - metabolic (osteoporosis, osteomalacia, Paget's disease)
 - rheumatologic (ankylosing spondylitis, polymyalgia rheumatica)
 - referred pain (perforated ulcer, pancreatitis, pyelonephritis, ectopic pregnancy, herpes zoster), no change with position

Physical Exam

- neurologic exam for L4, L5, S1 helps determine level of spinal involvement (muscle strength, sensation, reflexes)
- peripheral pulses
- special tests
 - straight leg raise (positive if pain at <70 degrees, aggravated by dorsiflexion of ankle), positive test is indicative of sciatica
 - crossed straight leg raise (more specific; raising of uninvolved leg elicits pain in leg with sciatica)
 - femoral stretch test (patient prone, knee flexed, examiner extends hip) to diagnose L4 radiculopathy

Red Flags for Back Pain

Bowel or bladder dysfunction
Anesthesia (saddle)
Constitutional symptoms/malignancy
Chronic disease
Paresthesias
Age >50 and mild trauma
IV drug use
Neuromotor deficits

Spinal Manipulative Therapy for Low Back Pain

Cochrane Database of Systematic Reviews 2004; Issue 1

Methods: Systematic review of 39 RCTs that compared spinal manipulative therapy with other therapies for low back pain.

Findings: For acute and chronic low back pain, spinal manipulative therapy was superior only to sham therapy or therapies judged to be ineffective or even harmful. It had no statistical or clinical advantage over analgesics, physical therapy, exercises, back school or physician care.

Conclusions: For acute and chronic low-back pain, there is no evidence that spinal manipulative therapy is superior to other treatments.

Massage for Low Back Pain

Cochrane Database of Systematic Reviews 2008; Issue 4

This meta-analysis of 13 randomized trials assessed the use of massage therapy for non-specific low back pain compared to other active or sham treatments.

Reviewer's Conclusions: For some patients with subacute or chronic non-specific low back pain, massage may be beneficial – especially with education and exercises. Some evidence suggests that acupuncture massage may be more effective than classic massage but more studies are required to confirm these results.

Non-steroidal Anti-inflammatory Drugs for Low Back Pain

Cochrane Database of Systematic Reviews 2008; Issue 1

This systematic review of 65 randomized and double-blind controlled trials assessed the effects of NSAIDs in treating non-specific low back pain and whether one type of NSAID was more effective.

Reviewer's Conclusions: In acute and chronic low back pain without sciatica, NSAIDs are slightly effective for short-term symptomatic relief. There was no difference between NSAIDs and placebo in patients with acute sciatica. No specific type of NSAID appears to be better.

Acupuncture and Dry-needling for Low Back Pain

Cochrane Database of Systematic Reviews 2005; Issue 1

This systematic review of 35 randomized control trials investigated the effectiveness of acupuncture on low back pain (LBP).

Conclusions: Effectiveness of acupuncture for acute LBP could not be assessed due to poor study design and low sample sizes. However, acupuncture is more effective for pain relief and functional improvement of chronic LBP than no treatment or sham treatment. Although acupuncture is not more effective than other therapies, it may be useful as an adjunct. Higher quality trials are needed.

Investigations

- plain films not recommended in initial evaluation
- indications for lumbar spine x-ray
 - no improvement after 1 month
 - fever >38°C
 - unexplained weight loss
 - prolonged corticosteroid use
 - significant trauma
 - progressive neuromotor deficit
 - suspicion of ankylosing spondylitis
 - history of cancer (rule out metastases)
 - alcohol/drug abuse (increased risk of osteomyelitis, trauma, fracture)
- CBC, ESR, urinalysis (infection, cancer)
- bone scan (infection, tumour, occult fracture), EMG if indicated
- consider CT or MRI (worsening neurologic deficits, infection, tumour)

Treatment

- reassurance and education if no underlying serious condition
 - 70% improve in 2 weeks, 90% in 6 weeks
- recommend comfort measures/conservative
 - limited bed rest (>2-4 days bed rest has potentially debilitating effects and no proven efficacy)
 - staying active (within limits of pain) leads to more rapid recovery and less chronic disability
 - activity modification (temporarily avoid activities that stress spine, e.g. heavy lifting, prolonged unsupported sitting)
 - heat or cold therapies
 - notes for work or WSIB to endorse “modified, appropriate work” vs. time off
 - encourage early return to work or activities
 - short course of massage may be beneficial
 - NO proven efficacy of spinal traction, TENS, biofeedback, injections (trigger-point, facet joint) or spinal manipulation; some evidence that acupuncture may be a helpful adjunct to other therapies
- pharmacological
 - acetaminophen
 - NSAIDs
 - muscle relaxants sometimes helpful but may cause drowsiness and are no better than NSAIDs; short term muscle relaxant use <7 days may be helpful
 - NOT narcotics
- if no improvement after one month of conservative therapy, consider further investigations
 - x-rays and appropriate labs in presence of any red flags
- surgical evaluation if
 - suspected cauda equina syndrome
 - worsening neurologic deficit
 - intractable pain not responding to conservative therapy

Table 31. Approach to Non-traumatic Low Back Pain

	Back dominant (Pain greatest above gluteal fold)		Leg dominant (Pain greatest below gluteal fold)	
History	Pattern 1 Worse with flexion Constant/intermittent	Pattern 2 Worse with extension Never worse with flexion Always intermittent	Pattern 3 Pain changes with back movement/position Currently/previously constant	Pattern 4 Worse with activity Improves with rest and posture change Intermittent/short duration
Physical Exam	Normal neuro exam <u>Fast responder</u> • Improves with extension <u>Slow responder</u> • No change or worsens with extension	Normal neuro exam ± improves with flexion	Leg pain can improve but not disappear Positive straight leg raise ± conduction loss <u>Fast responder</u> • Improves with specific back position <u>Slow responder</u> • Not better with position changes	No irritative findings ± conductive loss
Likely Pathology	Arising from intervertebral discs or adjacent ligaments	Posterior joint complex (associated ligaments and capsular structures)	Sciatica	Neurogenic claudication
Initial Management	Scheduled extension Lumbar roll Night lumbar roll Medication as required	Scheduled flexion Limited extension Night lumbar roll Medication as required	Prone extension Supine “Z” lie Lumbar roll Night lumbar roll Medication as required	Abdominal exercises Night lumbar roll Sustained flexion Medication as required

Adapted from: American Academy of Orthopaedic Surgeons. Acute Care: Nontraumatic Low Back Pain. *Orthopaedic Knowledge Update: Spine 2* 2001; 153-166

Menopause/HRT

- see Gynecology, GY32

Epidemiology

- mean age of menopause = 51.4 years
- a woman will spend over 1/3 of her life in menopause

Clinical Features

- urogenital tract: atrophy, vaginal dryness, incontinence
- blood vessels and heart: vasomotor instability, hot flashes, increased risk of heart disease
- bones: bone loss, fractures, loss of height
- brain: depression, mood swings, memory loss

Management

- encourage physical exercise, smoking cessation, and a balanced diet with adequate intake/supplementation of calcium/vitamin D (1500 mg/800 IU OD)
- hormone replacement therapy (HRT)
 - routine use of HRT is no longer recommended
 - regimens: cyclic estrogen + progesterone, continuous estrogen + progesterone, estrogen only (no uterus), estrogen ring, estrogen gel
 - helps with symptomatic relief of estrogen deprivation
 - decreases risk of osteoporotic fractures, colorectal cancer
 - increases risk of breast cancer, coronary heart disease, stroke, and pulmonary embolism
 - initiation of HRT requires a thorough discussion of each patient's history, symptoms and risk factors, and of the overall short and long-term benefits and risks
- consider venlafaxine, SSRI, gabapentin to ease vasomotor instability

Estrogen Plus Progestin and the Risk of Coronary Heart Disease

NEJM 2003; 349(6):523-34

Study: Randomized controlled trial, after a mean follow-up of 5.2 years. Planned duration was 8.5 years but the data and safety monitoring board recommended terminating the trial because the overall risks exceeded the benefits.

Patients: 16,608 postmenopausal women, age 50 to 79 years at base line.

Intervention: Conjugated equine estrogens (0.625 mg per day) plus medroxyprogesterone acetate (2.5 mg per day) or placebo.

Purpose: Final results with regard to estrogen plus progestin and CHD from the Women's Health Initiative (WHI).

Main Outcomes: Nonfatal MI or death due to coronary heart disease.

Results: Combined HRT was associated with a hazard ratio for coronary artery disease of 1.24. The elevation in risk was most apparent at one year (hazard ratio 1.81).

Conclusions: Estrogen plus progestin does not confer cardiac protection and may increase the risk of CHD among generally healthy postmenopausal women, especially during the first year after the initiation of hormone use. This treatment should not be prescribed for the prevention of cardiovascular disease.

Osteoarthritis

- see Rheumatology, RH4

Epidemiology

- most common form of arthritis seen in primary care
- prevalence: 10-12%, increases with age
- results in long-term disability in 2-3% of patients with OA
- almost everyone over the age of 65 shows signs of OA on x-ray, but only 33% of these will be symptomatic

Clinical Features

- pain with weight bearing, improved with rest
- morning stiffness or gelling <30 min
- deformity, bony enlargement, crepitus, limitation of movement
- usually affects distal joints of hands, spine, hips, and knees

Investigations

- no laboratory tests for the diagnosis of OA
- radiographic features: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes

Management

- goals: relieve pain, preserve joint motion and function, prevent further injury
- conservative
 - patient education, weight loss, exercise (OT/PT), assistive devices (canes, orthotics, raised toilet seats)
- pharmacological
 - keep in mind co-morbid conditions such as HTN, peptic ulcer disease, renal disease
 - medications do not alter natural course of OA
 - 1st line: acetaminophen 325-1000 mg qid prn (OA is not an inflammatory disorder)
 - 2nd line: NSAIDs [COX-2 selective NSAIDs (Celebrex®, Mobicox®) recommended if long-term therapy or if high risk for serious GI problems]
 - combination analgesics (e.g. acetaminophen and codeine)
 - intra-articular corticosteroid injections (not more than 3-4x/yr) may be helpful in acute flares (benefits last 4-6 wks, can be up to 6 mo)
 - intra-articular hyaluronic acid injections
 - topical NSAID (Pennsaid®)
 - capsaicin cream (Zostrix®)
- surgery
 - consider if persistent significant pain and functional impairment despite optimal pharmacotherapy (e.g. debridement, osteotomy, total joint arthroplasty)

- Hand (DIP, PIP, 1st CMC)
- Hip
- Knee
- 1st MTP
- L-spine (L4-L5, L5-S1)
- C-spine
- Uncommon: ankle, shoulder, elbow, MCP, rest of wrist

© Linda Coletti

Figure 10. Common Sites of Involvement in OA

Glucosamine Therapy for Treating Osteoarthritis

Cochrane Database of Systematic Reviews 2005; Issue 2

This meta-analysis of 25 single- and double-blinded randomized controlled trials with 4963 patients compared glucosamine treatment, administered by any route, against placebo or another treatment.

Reviewer's Conclusions: Glucosamine can decrease pain and functional impairment resulting from OA and is not associated with any side effects compared to placebo. Differences in the effectiveness of Rotta and non-Rotta preparations highlight variability between glucosamine preparations and patients should be made aware of this.

Osteoporosis

- see [Endocrinology](#), E43
- age-related disease characterized by decreased bone mass and increased susceptibility to fractures
- affects 1 in 4 Canadian women and 1 in 8 Canadian men

Table 32. Risk Factors for Osteoporosis

Major Risk Factors	Minor Risk Factors
Age >65 years	Rheumatoid arthritis
Vertebral compression fracture	Past history of clinical hyperthyroidism
Fragility fracture after age 40	Chronic anticonvulsant therapy
Family history of osteoporotic fracture (especially maternal hip fracture)	Low dietary calcium intake
Systemic glucocorticoid therapy of >3 months duration	Smoker
Malabsorption syndrome	Excessive alcohol intake
Primary hyperparathyroidism	Excessive caffeine intake
Propensity to fall	Weight <57 kg
Osteopenia apparent on x-ray film	Weight loss >10% of weight at age 25
Hypogonadism	Chronic heparin therapy
Early menopause (before age 45)	

Diagnosis

- defined in terms of a bone mineral density (BMD) T-score < -2.5 SD
- osteopenia: BMD T-score between -1.0 SD and -2.5 SD
- mass BMD screening is not recommended
- measure BMD in
 - all patients >65 years of age
 - all patients with one major or two minor risk factors for osteoporosis (see Table 32)
- measure BMD using dual x-ray absorptiometry (DEXA)
- suspect osteoporosis in women with back pain, a decrease in height or thoracic kyphosis

Management

- institute a fall prevention program for those at risk; optimize eyesight
- lifestyle
 - weight bearing exercise, smoking cessation, decrease alcohol intake
- diet
 - for women without documented osteoporosis, calcium and vitamin D supplementation alone prevents osteoporotic fractures (grade B recommendation)
 - calcium (1500 mg/day) and vitamin D (800 IU/day) intake in diet or supplements
- pharmacological
 - women with osteoporosis: bisphosphonates (e.g. risedronate, alendronate) or Selective Estrogen Receptor Modulators (e.g. raloxifene) prevent osteoporotic fractures (grade A to B recommendation)
 - women with severe osteoporosis (osteoporosis plus at least 1 fragility fracture): alendronate, risedronate, parathyroid hormone (limited duration), raloxifene, etidronate and oral pamidronate therapy (grade A to B recommendation)
 - if none of these drugs is tolerated, hormone replacement therapy (HRT) or calcitonin can be considered
 - severe esophagitis is the major side effect of bisphosphonate use
- HRT, calcitonin
 - there is fair evidence that combined estrogen-progestin therapy decreases the incidence of total, hip and nonvertebral fractures; however, for most women the risks may outweigh the benefits (grade D recommendation), see [Gynecology](#), GY33

Calcium Content of Some Common Food

1 cup milk – 300 mg
 ¾ cup yogurt – 295 mg
 ½ can salmon w/bones – 240 mg
 ¾ cup cooked broccoli – 50 mg
 1 medium orange – 50 mg

Osteoporosis Society of Canada.
www.osteoporosis.ca

DDx of Rash

- Contact dermatitis
- Herpes zoster
- Eczema
- Erythema nodosum
- Lichen planus
- Psoriasis
- Lupus erythematosus
- Drug reaction

Rash

- see [Dermatology](#), D4

History

- age
- duration of lesions
- associated symptoms: itching, fever, pain
- travel history
- sick contacts
- past medical history, medications, sexual history
- vaccinations

Physical Exam

- vitals
- describe lesion (SCALD)
 - Size
 - Colour (e.g. hyperpigmented, hypopigmented, erythematous)
 - Arrangement (e.g. solitary, linear, reticulated, grouped, herpetiform)
 - Lesion morphology
 - Distribution (e.g. dermatomal, intertriginous, symmetrical/asymmetrical, follicular)

Investigations

- depends on history; may include swab of lesion, biopsy

Management

- depends on symptoms and cause of rash
- refer to dermatologist as needed

**Common DDx of Pruritic Rash**

- Eczema
- Contact dermatitis
- Insect bites
- Scabies
- Urticaria
- PUPPP (during pregnancy)
- Drug reaction

Rhinorrhea

- see Otolaryngology, OT23

Differential Diagnosis

- common cold, sinusitis, influenza, strep pharyngitis, ear infections, vasomotor rhinitis
- allergies, contact with substances/tearing
- foreign body
- opioid withdrawal
- basilar skull fracture

Investigations

- CBC, throat swab, nasopharyngeal swab, x-ray if injury, allergy testing

Management

- saline nasal rinse
- consider medications: antihistamines, decongestants, corticosteroid nasal spray

Sexually Transmitted Infections (STIs)

- see Gynecology, GY26

Definition

- diverse group of infections caused by multiple microbial pathogens
- transmitted by either secretions or fluids from mucosal surfaces

Epidemiology

- high incidence rates worldwide
- Canadian prevalence rates in clinical practice
 - common: chlamydia, gonorrhea, PID, genital warts, genital herpes (increasing incidence)
 - less common: hepatitis B, HIV & syphilis (both increasing in incidence), trichomoniasis
 - rare: chancroid, lymphogranuloma venereum, granuloma inguinale
- genital tract infections (NOT sexually transmitted): vulvovaginal candidiasis (VVC), bacterial vaginosis (BV)
- three most common infections associated with vaginal discharge in adult women are BV, VVC, and trichomoniasis

History

- sexual history
 - level of sexual activity and type (oral, anal and/or vaginal intercourse)
 - age of first intercourse, sexual orientation, sexual activity during travel
 - total number of partners in the past year/month/week and duration of involvement with each

**Risk Factors**

- Sexually active males and females <25 years old
- Early age of 1st intercourse
- Street involved and/or substance use, men who have sex with men
- Unprotected sex, previous STI, contact with known case of STI
- New partner in past 2 months, >2 partners in past 12 months

When a STI is detected in a prepubertal child, evaluation for sexual abuse is prudent.

Prophylactic Vaccination Against Human Papillomavirus Infection and Disease in Women: A Systematic Review of Randomized Controlled Trials

CMAJ 2007; 177(5):469-479.

Purpose: To evaluate prophylactic HPV vaccination in preventing high- and low-grade cervical lesions, persistent HPV infection, external genital lesions, adverse events, and death using meta-analysis.

Studies: 9 reports from 6 different trials with 40 323 patients were included and all studies were of high methodologic quality. Three studies used the quadrivalent vaccine, two used the bivalent, and one used a monovalent. The longest mean duration of follow-up was 48 months.

Results: Prophylactic HPV vaccination decreased the frequency of high-grade cervical lesions caused by vaccine-type HPV strains compared to the control group (Peto odds ratio 0.14 (95% CI 0.09-0.21)). Vaccinations also prevented persistent HPV infection, low-grade lesions and genital warts and the reported adverse events were mostly minor.

Compared to placebo, there was no difference in serious adverse events or death.

Conclusion: Prophylactic HPV is highly efficacious in preventing infection and precancerous cervical disease in women aged 15-25 who have not previously been infected with vaccine-type HPV strains.

- STI history
 - STI awareness, previous STIs and testing, partners with previous STIs
 - contraception history, last Pap test and results
 - local symptoms such as genital burning, itching, discharge, sores, vesicles
 - associated symptoms such as fever, arthralgia, lymphadenopathy
 - partner communication with regards to STIs

Investigations/Screening

- individuals at increased risk, even those who are asymptomatic, should be screened for chlamydia, gonorrhea, HIV, hepatitis B, and syphilis
- Pap test if none performed in the preceding 12 months

Management

- primary prevention is vastly more effective than treating STIs and their sequelae
- offer hepatitis B vaccine if not immune, offer Gardasil® to women under age of 26
- discuss STI risk factors (e.g. decreasing the number of sexual partners)
- direct advice to ALWAYS use condoms or to abstain from intercourse
- condoms not 100% effective against HPV, herpes, genital warts
- a STI patient is not considered treated until the management of his/her partner(s) is ensured (contact tracing by Public Health)
- patients should abstain from sexual activity until treatment completion
- mandatory reporting: chlamydia, gonorrhea, hepatitis B, HIV, syphilis

Table 33. Diagnosis and Treatment of Common STI

	Signs and Symptoms	Investigations	Treatment	Complications
Gonococcal Urethritis/Cervicitis (<i>Neisseria gonorrhoeae</i>)	M: burning, irritation, unexplained pyuria, urethral discharge F: mucopurulent endocervical discharge, dysuria, pelvic pain, vaginal bleeding M and F: often asymptomatic, can involve rectal symptoms in cases of unprotected anal sex	M: urine PCR, urethral swabs for stain and culture F: endocervical swab for culture, vaginal swab for wet mount and Gram stain	Cefixime 400 mg PO, single dose + non-gonococcal urethritis/cervicitis Rx* F/U in 2 wks for test of cure if symptoms persist	Arthritis, increased risk of acquiring and transmitting HIV M: urethral strictures, epididymitis, infertility F: PID, infertility, ectopic pregnancy, perinatal infection, chronic pelvic pain
Non-Gonococcal Urethritis/Cervicitis (Usually <i>Chlamydia trachomatis</i> **)	~70% asymptomatic If symptoms appear (usually 2-6 wks after infection) then similar to gonococcal symptoms (see above)	Same as above	Azithromycin 1 g PO, single dose + gonococcal urethritis/cervicitis Rx* Same follow up as above	Same as above
Human Papilloma Virus (genital warts)	Most are asymptomatic M: cauliflower lesions (condylomata acuminata) on skin/mucosa of penile/anal area F: cauliflower lesions AND/OR pre-neoplastic/neoplastic lesions on cervix, vagina, or vulva	None needed if simple condylomata Potential biopsy of suspicious lesions F: screening for cervical dysplasia through regular Pap smears	For condylomata: cryotherapy, electrocautery, topical therapy (podophyllotoxin) For cervical dysplasia: colposcopy and possible excision, dependent on grade of lesion	M + F: anal cancer F: cervical/vaginal/vulvar cancer M who have sex w/ M + F who have receptive anal sex: rectal CA
Genital Herpes (HSV-1 and -2)	1° episode: painful vesiculoculcerative genital lesions, ± tender lymphadenopathy and fever, protracted course Recurrent episodes: less extensive lesions, shorter course, may have "trigger factors"	Swab of vesicular content for culture, type-specific serologic testing for HSV-1 and HSV-2 antibodies	<u>1° episode:</u> Acyclovir 200 mg PO 5x/day for 5-10d, OR Famciclovir 250 mg PO tid for 5d, OR Valacyclovir 1000 mg PO bid for 10d <u>Recurrent Episodes:</u> Valacyclovir 500 mg PO bid OR 1 g qd for 3d, OR Famciclovir 125 mg PO bid for 5d, OR Acyclovir 200 mg PO 5x/d for 5d, or 800 mg PO tid for 2d	Genital pain, urethritis, aseptic meningitis, cervicitis, increased risk of acquiring and transmitting HIV
Infectious Syphilis (<i>Treponema pallidum</i>)	1°: painless sore 2°: rash and flu-like symptoms Latent Phase: asymptomatic 3°: neurologic, cardiovascular, and tissue complications	Specimen collection from 1° and 2° lesions; screen high risk individuals with serologic syphilis testing; universal screening of pregnant women	Benzathine penicillin G IM (dose depends on stage) Notify partners (last 3-12 mths) Continuous follow-up and testing until patients are seronegative	Increased risk of acquiring and transmitting HIV Chronic neurologic and cardiovascular sequelae

M = Males; F = Females

*N.B. if urethritis/cervicitis is suspected, always treat for both gonococcal and non-gonococcal types (i.e. Cefixime AND Azithromycin)

**Most common reportable STI in Canada

Sinusitis

- see Otolaryngology, OT25

Definition

- inflammation of the mucous membranes of the nasal cavity and paranasal sinuses, fluid within these cavities, and/or the underlying bone

Etiology

- classifications:
 - acute: <4 weeks
 - recurrent: 4 or more episodes per year, each lasting at least 10 days, with an absence of symptoms in between
 - chronic: ≥12 weeks
- common pathogens: rhinovirus, influenza, parainfluenza, *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*

Risk Factors

- medical conditions: respiratory infections, allergic rhinitis, cystic fibrosis, immunodeficiency
- anatomic: deviated septum, polyps, adenoid hypertrophy, tumour
- irritants: environmental, tobacco smoke, air pollution, chlorine
- iatrogenic: topical decongestant overuse, cocaine, trauma

Investigations

- radiography is warranted only when the diagnosis of sinusitis is in doubt
- all patients with pronounced frontal headaches should have a radiograph performed to rule out frontal sinusitis
- CT scans are not cost-effective and should not be used routinely to diagnose sinusitis

Management

- acute sinusitis
 - 70% of patients will resolve without antibiotics
 - oral analgesics/antipyretics for pain/fever
 - nasal saline rinse and humidification may be beneficial
 - short-term use of topical or systemic decongestants may be useful adjuncts
 - antihistamines are contraindicated
 - antibiotics limited to those diagnosed with acute bacterial sinusitis through history and physical
 - ♦ 1st line: amoxicillin x 10 days (TMP-SMX or doxycycline if penicillin allergic)
 - ♦ 2nd line: amoxicillin+clavulanate, clarithromycin, azithromycin, cefuroxime
 - referral to ENT if
 - ♦ failure of second-line therapy
 - ♦ ≥3 episodes per year
 - ♦ development of complications (mucocoele, orbital extension, meningitis, intracranial abscess, venous sinus thrombosis)

Sinusitis Score

- Maxillary toothache (1)
 - History of coloured nasal discharge (1)
 - No improvement with decongestants (1)
 - Abnormal transillumination (1)
 - Purulent secretion on exam (1)
- Other signs: nasal congestion, facial pain/pressure

Probability of Sinusitis By Score

- 0 – 9%
- 1 – 21%
- 2 – 40%
- 3 – 63%
- 4 – 81%
- 5 – 92%

Ebell, MH. *Evidence-based diagnosis: a handbook of clinical prediction rules*. 2001.

Sleep Disorders

- see also Respirology, R32

Definition

- most often characterized by one of three complaints:
 - insomnia
 - ♦ difficulty falling asleep, difficulty maintaining sleep, early-morning wakening, non-refreshing sleep
 - parasomnias
 - ♦ night terrors, nightmares, restless leg syndrome, somnambulism (performing complex behaviour during sleep with eyes open but without memory of event)
 - excessive daytime sleepiness

Epidemiology

- 1/3 of patients in primary care setting have occasional sleep problems
- 10% have chronic sleep problems
- more common in women and with increasing age

Etiology

- primary sleep disorders
 - primary insomnia, obstructive sleep apnea, restless legs syndrome, narcolepsy, periodic limb movements of sleep

- secondary causes
 - medical: COPD, asthma, CHF, hyperthyroidism, chronic pain, BPH
 - drugs: alcohol, caffeine, nicotine, beta-agonists, antidepressants, steroids
 - psychiatric disorders: especially mood and anxiety disorders
 - lifestyle factors: shift work

Investigations

- complete sleep diary every morning for 1-2 wks
 - record bedtime, sleep latency, total sleep time, awakenings, quality of sleep
- rule out specific medical problems (CBC + differential, TSH)
- sleep study referral if suspect periodic leg movements of sleep or sleep apnea
- night time polysomnogram or daytime multiple sleep latency test

Treatment

- treat any suspected medical or psychiatric cause
- psychologic treatment
 - sleep hygiene: avoid caffeine, nicotine, alcohol; exercise regularly; comfortable sleep environment; regular sleep schedule; no napping
 - relaxation therapy: deep breathing, meditation, biofeedback
 - stimulus control therapy: re-association of bed/bedroom with sleep; re-establishment of a consistent sleep-wake schedule; reduce activities that cue staying awake
 - sleep restriction therapy: total time in bed should closely match the total sleep time of the patient (improves sleep efficacy)
- pharmacologic treatment
 - short-acting benzodiazepines: e.g. lorazepam, oxazepam, temazepam, should be used <7 consecutive nights to break cycle of chronic insomnia

Specific Problems

- primary insomnia
 - majority of cases
 - person reacts to insomnia with fear or anxiety around bedtime or with a change in sleep hygiene; can progress to a chronic disorder (psychophysiological insomnia)
- snoring
 - results from soft tissue vibration at the back of the nose and throat due to turbulent airflow through narrowed air passages
 - risk factors: male gender, obesity, alcohol consumption, ingestion of tranquilizers or muscle relaxants, and smoking
 - PE: obesity, nasal polyps, septal deviation, hypertrophy of the nasal turbinates, and enlarged uvula and tonsils
 - investigations (only if severely symptomatic): nocturnal polysomnography and airway assessment (CT/MRI)
 - treatment
 - ♦ sleep on side (position therapy), weight loss
 - ♦ nasal dilators (noninvasive external dilator made with elastic adhesive backing applied over nasal bridge), tongue-retaining devices, mandibular advancement devices
 - at risk of developing obstructive sleep apnea
- obstructive sleep apnea (OSA)
 - apnea resulting from upper airway obstruction due to collapse of the base of the tongue, soft palate with uvula, and epiglottis
 - respiratory effort is present
 - leads to a distinctive snorting, choking, awakening type pattern as body rouses itself to open airway = resuscitative breath
 - apneic episodes can last from 20 sec to 3 min; can have 100-600 episodes/night
 - diagnosis based on nocturnal polysomnography: >15 apneic episodes per hour of sleep with arousal recorded
 - consequences
 - ♦ daytime somnolence, non-restorative sleep
 - ♦ poor social and work performance
 - ♦ mood changes: anxiety, irritability, depression
 - ♦ sexual dysfunction: poor libido, impotence
 - ♦ morning headache (due to hypercapnia)
 - ♦ HTN (2x increased risk), CAD (3x increased risk), stroke (4x increased risk), arrhythmias
 - ♦ pulmonary hypertension, RV dysfunction, cor pulmonale (due to chronic hypoxemia)
 - ♦ memory loss, decreased concentration, confusion
 - investigations
 - ♦ blood gas not helpful, TSH if clinically indicated
 - ♦ evaluate BP, inspect nose, oropharynx (i.e. for enlarged adenoids or tonsils)
 - ♦ nocturnal polysomnography (sleep lab)

Risk Factors for Obstructive Sleep Apnea

- 2% women, 4% men between ages 30-60
- Obesity causing upper airway narrowing: BMI >28 kg/m² present in 60-90% of cases
- Children: commonly tonsils, adenoids
- Aging which causes decreased muscle tone
- Persistent URTIs, allergies, nasal tumours, hypothyroidism (due to macroglossia)
- Family history

- treatment
 - ♦ modifying factors: avoid sleeping supine, lose weight, avoid alcohol, sedatives, narcotics, inhaled steroids if nasal swelling present
 - ♦ primary treatment of OSA is CPAP: maintains patent airway in 95% of OSA cases
 - ♦ dental appliances to modify mandibular position
 - ♦ surgery: somnoplasty, tonsillectomy and adenoidectomy (in children), uvulopalatopharyngoplasty (UPPP)
 - ♦ report patient to Ministry of Transportation if OSA is not controlled by CPAP
- central sleep apnea
 - definition
 - ♦ brain fails to send appropriate signals to the breathing muscles to initiate respirations
 - ♦ defining feature is absent respiratory effort
 - ♦ often secondary to CNS diseases: brainstem infarction, infection, neuromuscular disease
 - investigations: PFTs, nocturnal polysomnography, MRI
 - treatment: CPAP or mechanical ventilation (if brainstem origin)
 - prognosis: poor

Sore Throat (Pharyngitis)

Definition

- inflammation of the oropharynx
- may be caused by a wide range of infectious organisms, most of which produce a self-limited infection with no significant sequelae

Etiology

- viral
 - adenovirus, rhinovirus, influenza virus, RSV, EBV, coxsackie virus, herpes simplex virus, CMV, HIV
- bacterial
 - group A beta-hemolytic *Streptococcus* (GABHS)
 - group C and G beta-hemolytic *Streptococcus*, *Neisseria gonorrhoeae*, *Chlamydia pneumoniae*, *Mycoplasma pneumoniae*, *Corynebacterium diphtheriae*

Epidemiology

- viral
 - most common cause, occurs year round
- bacterial
 - Group A beta-hemolytic *Streptococcus*
 - ♦ most common bacterial cause
 - ♦ 5-15% of adult cases and up to 50% of all pediatric cases of acute pharyngitis
 - ♦ most prevalent between 5-17 years old
 - ♦ occurs most often in winter months

Clinical Features

- viral
 - pharyngitis, conjunctivitis, rhinorrhea, hoarseness, cough
 - nonspecific flu-like symptoms such as fever, malaise, and myalgia
 - often mimics bacterial infection
 - coxsackie virus (hand, foot and mouth disease)
 - ♦ primarily late summer, early fall
 - ♦ sudden onset of fever, pharyngitis, headache, abdominal pain and vomiting
 - ♦ appearance of small vesicles that rupture and ulcerate on soft palate, tonsils, pharynx
 - ♦ ulcers are pale gray, several mm in diameter, have surrounding erythema, may appear on hands and feet
 - herpes simplex virus
 - ♦ like coxsackie virus but ulcers are fewer and larger
 - EBV (infectious mononucleosis)
 - ♦ pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
- bacterial
 - symptoms: sore throat, absence of cough, fever, malaise, headache, abdominal pain
 - signs: fever, tonsillar or pharyngeal erythema/exudate, swollen/tender anterior cervical nodes
 - complications
 - ♦ rheumatic fever
 - ♦ glomerulonephritis
 - ♦ suppurative complications (abscess, sinusitis, otitis media, pneumonia, cervical adenitis)
 - ♦ meningitis
 - ♦ impetigo

Red Flags in Patients with "Sore Throat"

1. Persistence of symptoms longer than 1 week without improvement
2. Respiratory difficulty, particularly stridor
3. Difficulty in handling secretions (peritonsillar abscess)
4. Difficulty in swallowing (Ludwig's angina)
5. Severe pain in the absence of erythema (supraglottitis/epiglottitis)
6. A palpable mass (neoplasm)
7. Blood in the pharynx or ear (trauma)

Investigations

- suspected GABHS
 - see Table 34 for approach to diagnosis and management of GABHS
 - gold standard for diagnosis is throat culture
 - rapid test for streptococcal antigen: high specificity (95%), low sensitivity (50-90%)
 - ♦ if rapid test positive, treat patient
 - ♦ if rapid test negative, take culture and call patient if culture positive to start antibiotics
 - suspected EBV (infectious mononucleosis)
 - ♦ peripheral blood smear, heterophile antibody test (i.e. the latex agglutination assay, or “monospot”)

Table 34. Sore Throat Score: Approach to Diagnosis and Management of GABHS

	POINTS				
Cough absent?					1
History of fever >38°C?					1
Tonsillar exudate?					1
Swollen, tender anterior nodes?					1
Age 3-14 years?					1
Age 15-44 years?					0
Age >45 years?					-1
In communities with moderate levels of strep infection (10-20% of sore throats):					
Score	0	1	2	3	4
Chance patient has strep	2-3%	3-7%	8-16%	19-34%	41-61%
Suggested action	NO culture or antibiotic		Culture all, treat only if culture is positive		Culture all, treat with antibiotics on clinical grounds ¹

¹Clinical grounds include a high fever or other indicators that the patient is clinically unwell and is presenting early in the course of the illness.

Limitations: *This score is not applicable to patients less than 3 years of age.

*If an outbreak or epidemic of illness caused by GAS is occurring in any community, the score is invalid and should not be used.

Adapted from: Centor RM et al. *Med Decis Making* 1981; 1:239-46. McIsaac WJ, White D, Tannenbaum D, Low DE. *CMAJ* 1998; 158(1):75-83.

Management

- GABHS (see Table 34)
 - no increased incidence of rheumatic fever with 48-hour delay in treatment
 - incidence of glomerulonephritis is not decreased with antibiotic treatment
 - antibiotic treatment: see *Antimicrobial Quick Reference*, FM50
 - routine follow-up and/or post-treatment throat cultures are not required for most patients
 - follow-up throat culture recommended only for: patients with history of rheumatic fever, patients whose family member has history of acute rheumatic fever, suspected strep carrier
- viral pharyngitis
 - antibiotics NOT indicated
 - symptomatic therapy: acetaminophen/NSAIDs for fever and muscle aches, decongestants
- infectious mononucleosis (EBV)
 - antibiotics NOT indicated; administering ampicillin produces rash
 - self-limiting course; rest during acute phase is beneficial
 - if acute airway obstruction, give corticosteroids, consult ENT
 - supportive care, i.e. acetaminophen or NSAIDs for fever, sore throat, malaise
 - avoid heavy physical activity and contact sports for at least one month or until splenomegaly resolves because of risk of splenic rupture

Complementary and Alternative Medicine (CAM)

Epidemiology

- 50-75% of Canadians report some use of CAM over their lifetime, and only half will disclose this use to their physician
- use is highest in Western provinces, lowest in Atlantic provinces
- more likely to be used by younger patients, those with higher education and income
- examples: chiropractic, acupuncture, massage, naturopathy, homeopathy, traditional Chinese medicine, craniosacral therapy, osteopathy
- most commonly used for: back/neck problems, gynecological problems, anxiety, headaches, digestive problems and chronic fatigue syndromes

Herbal Products

- over 50% of Canadians use natural health products
- most commonly used include echinacea, ginseng, ginkgo, garlic, St John's Wort, and soy
- relatively few herbal products have been shown to be effective in clinical trials
- many patients believe herbal products are inherently safe and are unaware of potential side effects and interactions with conventional medicines
- all natural health products (NHPs) must be regulated under *The Natural Health Products Regulations* as of January 1, 2004, including herbal remedies, homeopathic medicines, vitamins, minerals, traditional medicines, probiotics, amino acids and essential fatty acids (e.g. omega-3)
- always ask patients whether they are taking any herbal product, herbal supplement or other natural remedy. Further questions may include:
 - Are you taking any prescription or non-prescription medications for the same purpose as the herbal product?
 - Are you allergic to any plant products?
 - Are you pregnant or breastfeeding?
- information resources: National Centre for CAM (www.nccam.nih.gov), Health Canada website

Table 35. Common Herbal Products

Common Name	Reported Uses	Possible Adverse Effects	Possible Drug Interactions
Black cohosh	Menopausal symptoms, PMS, labour induction, arthritis	Hepatitis, liver failure, headaches, GI discomfort, heaviness in legs, weight problems	None reported
Chamomile	Mild sedative, anxiolytic, GI complaints, common cold	Allergic/contact dermatitis, anaphylaxis	Anxiolytics, sedatives
Echinacea	Common cold, flu, wound treatment, urinary tract infections, cancer	Hypersensitivity, hepatotoxicity with prolonged use, avoid use if immunosuppressed	Potentiates warfarin
Evening primrose	Dysmenorrhea, menopausal sx, inflammation, allergies, eczema, arthritis, MS	Headache, restlessness, nausea, diarrhea, may decrease seizure threshold	Anticoagulants, antiplatelets
Feverfew	Migraine prevention, rheumatoid arthritis, anti-inflammatory	Anxiety, upset stomach, skin rash, miscarriage	Anticoagulants, antiplatelets
Flaxseed oil	Laxative, menopausal sx, source of omega-3 fatty acids	Diarrhea	Do not take with other medications as fibre content can bind drugs
Garlic	Elevated lipids, hypertension, hyperglycemia, antimicrobial	GI irritation, contact dermatitis, may increase post-op bleeding	Anticoagulants, potentiates antihypertensives
Ginger	Nausea, motion sickness, dyspepsia, anti-inflammatory	Heartburn, not to be used for morning sickness	None known
Ginkgo biloba	Increases peripheral circulation (AD, dementia, intermittent claudication), premenstrual syndrome, vertigo	Headache, cramping, bleeding, mild digestive problems; reports of intracranial hemorrhage	Anticoagulants, thiazide diuretics, MAO inhibitors
Ginseng	Energy enhancer, decreases stress, adjunct support for chemotherapy/radiation	Hypertension, nervousness, insomnia, breakthrough bleeding, palpitations	Stimulant medications, antihypertensives, hormonal therapies
Glucosamine (Chondroitin)	Osteoarthritis	GI distress, headache, drowsiness, palpitations	Caution if shellfish allergy
Saw palmetto	BPH, adjunct to finasteride	Mild GI distress	Alpha-adrenergics, finasteride
St. John's Wort	Mild to moderate depression	Photosensitivity, increased liver enzymes, drowsiness, dizziness, nausea, headaches	CNS depressants, C/I with indinavir
Valerian root	Sedative, anxiolytic, muscle relaxant, PMS	Drowsiness, headache, digestive problems, paradoxical insomnia	CNS depressants, antihistamines

References: Zink T, Chaffin J. Herbal "health" products: What family physicians need to know, *American Family Physician* 1998; 58(5):1133-1140.; NIH National Center for Complementary and Alternative Medicine website (<http://nccam.nih.gov>)

St. John's Wort for Depression

Cochrane Database of Systematic Reviews 2005; Issue 2

A meta-analysis of 37 trials, including 26 which compared St. John's Wort with placebo and 14 which compared St. John's Wort with standard antidepressants. The main outcome measure was the ratio of responders to non-responders, and the main outcome measure for adverse effects was the number of patients dropping out due to adverse experiences. Significant heterogeneity was noted among placebo-controlled trials, but trials were statistically homogeneous for trials comparing St. John's Wort with antidepressants. For major depression, compared with placebo, the OR for 6 larger trials was 1.15 (95% CI 1.02-1.29) and 5 smaller trials, 2.06 (95% CI 1.65-2.59). Compared with SSRIs and tricyclics, the response rates were 0.98 (95% CI 0.85-1.12) and 1.03 (95% CI 0.93-1.14), respectively. Fewer patients on St. John's Wort dropped out due to adverse effects compared to those taking tricyclics (OR 0.25; 95% CI 0.14-0.45), and a similar but non-significant trend was seen when compared with SSRIs (OR 0.60; 95% CI 0.31-1.15). Drawing solid conclusions is difficult given the degree of study heterogeneity and number of conflicting studies.

Primary Care Models

Table 36. Primary Care Models

	Characteristics
Comprehensive Care Model	<ul style="list-style-type: none"> Model for GPs in solo practice with limited after-hours availability
Family Health Team	<ul style="list-style-type: none"> Groups of health care professionals (e.g. GPs, RNs, NPs, dieticians, social workers) Wider range of services (e.g. rehabilitation, palliative care), with increased after-hours availability Receives provincial funding for allied health
Family Health Group	<ul style="list-style-type: none"> Group of ≥ 3 GPs, with some after-hours availability as well as on-call to telephone health advisory services Payment model: fee-for-service plus premiums
Family Health Network	<ul style="list-style-type: none"> Group of ≥ 3 GPs; can utilize nurse practitioners, with telephone health advisory services to provide around the clock primary care coverage Payment model: salary-based
Family Health Organization	<ul style="list-style-type: none"> Groups of GPs working with allied health, with after-hours clinics and 24h telephone health advisory services Payment model: fee-for-service plus premiums

Antimicrobial Quick Reference*

Condition	Microorganisms	Antimicrobial
RESPIRATORY/ENT		
Acute Rhinitis (common cold)	Viral: Rhinovirus, Adenovirus, RSV, Influenza, etc.	None
Pharyngitis (sore throat)	Viral: Adenovirus, Rhinovirus	None
Strep Pharyngitis	Group A beta-Hemolytic <i>Strep</i>	<p><i>Pediatric:</i></p> <p>pen V 25-50 mg/kg/d PO div. q6h x 10d amox/clav 45 mg/kg/d PO div. q12h x 10d clarithromycin 15 mg/kg/d PO div. bid x 10d azithromycin 12 mg/kg/d PO x 5d</p> <p><i>Adults:</i></p> <p>pen V 500mg PO bid or 250 mg qid x 10d cefuroxime 250 mg PO bid x 4d clarithromycin 250 mg PO bid x 10d azithromycin 500 mg PO once, then 250 mg daily x4d</p> <p>Penicillin allergy: erythromycin</p>
Sinusitis	<i>S. pneumoniae</i> <i>H. influenzae</i> <i>M. catarrhalis</i> Group A <i>Strep</i> Anaerobes <i>S. aureus</i>	<p>1st line: amoxicillin 1 g PO tid x 10d (If penicillin allergy: TMP/SMX DS 1 tab PO bid)</p> <p>2nd line: amox/clavulin 2000/125 mg PO bid x 10d</p> <p>3rd line: clarithromycin XL 1000 mg PO OD x 10d</p>
Acute Otitis Media	Viral <i>S. pneumoniae</i> <i>H. influenzae</i> <i>M. catarrhalis</i>	<p>Treat if under 24 months old for 7d. Otitis Externa	<i>Pseudomonas</i> <i>S. aureus</i> Fungal	<p>Diabetic:</p> <p>ciprofloxacin 500 mg PO bid x 14d</p> <p>Non-diabetic:</p> <p>1st line: Buro-sol® 2-3 drops tid 2nd line: Cortisporin® otic solution 4 drops tid</p>
Bronchitis	Viral: Rhinovirus, Coronavirus, Adenovirus, RSV, Influenza, Parainfluenza <i>S. pneumoniae</i> <i>H. influenzae</i> <i>M. pneumoniae</i> <i>C. pneumoniae</i>	Abx not recommended for acute bronchitis

Condition	Microorganisms	Antimicrobial
RESPIRATORY/ENT		
Community Acquired Pneumonia	Susceptible to beta-lactams: <i>S. pneumoniae</i> <i>H. influenzae</i> <i>S. aureus</i>	Adult dosing (no respiratory comorbidities): erythromycin 500 mg PO qid x 7-10d clarithromycin 250-500 mg PO bid x 7-10d azithromycin 500 mg PO 1st dose then 250 mg PO OD x 4d
	Not susceptible to beta-lactams: <i>Mycoplasma</i> <i>Chlamydia pneumoniae</i> <i>Legionella pneumoniae</i>	doxycycline 200 mg PO 1st dose then 100 mg PO bid x 7-10d
Dental Infections/ Periapical and Periodontal Abscesses	Oral Flora	Pen V potassium 500 mg PO qid x 7-10d clindamycin 300 mg PO qid x 7-10d
GASTROENTEROLOGY		
Diarrhea – Enteritis	<i>Shigella</i> <i>Salmonella</i> <i>Campylobacter</i> <i>E. coli</i> <i>Yersinia</i>	Abx if severe, treat according to specific organism isolated
Diarrhea – post abx (common with clindamycin)	<i>C. difficile</i>	Add metronidazole 500 mg PO tid x 10-14d or vancomycin 125 mg PO qid
Peptic Ulcer Disease (non-NSAID related)	<i>H. pylori</i>	HP-PAC (7 blister card pack): lansoprazole 30 mg PO bid + clarithromycin 500 mg PO bid + amoxicillin 1 g PO bid x 7d Penicillin allergy: metronidazole 500 mg PO bid + clarithromycin 250 mg PO bid + omeprazole 20 mg PO bid x 7-14d
GENITOURINARY		
UTI/Cystitis	<i>Klebsiella</i> <i>E. coli</i> <i>Enterobacter</i> <i>Enterococci</i> <i>Proteus</i> <i>S. saprophyticus</i>	<20% <i>E. coli</i> resistance to TMP-SMX: TMP-SMX 1 DS tablet PO bid x 3d >20% <i>E. coli</i> resistance to TMP-SMX: ciprofloxacin 250 mg PO bid or cipro ER 500mg daily x3d Nitrofurantoin (Macrobid®) 100 mg PO bid x 5d if sulfa allergy Pregnancy: amoxicillin 250-500 mg PO tid x 7d N.B. nitrofurantoin is contraindicated in pregnancy after 38 wks
Vaginal Candidiasis/Yeast	<i>Candida</i>	fluconazole 150 mg PO single dose miconazole 2% vag. cream = Monistat 7®: One applicator (5 g) intravag. qhs x 7d
Lice: Head and Pubic (Crabs)	<i>Pediculosis humanus capitis</i> <i>Phthirus pubis</i>	permethrin cream 1%: apply as liquid on to washed hair for 10 min, then rinse. Repeat in 1 wk
Gonorrhea/Chlamydia	<i>N. gonorrhoeae</i> <i>C. trachomatis</i>	cefixime 400 mg PO single dose + azithromycin 1 g PO single dose or doxycycline 100 mg PO bid x 7d
Herpes	Herpes simplex virus	acyclovir 400 mg PO tid x 7-10d valacyclovir 1 g PO bid x 10d famciclovir 250 mg PO tid x5d
Bacterial Vaginosis	Unclear, associated with: <i>Gardnerella vaginalis</i> <i>Mycoplasma hominis</i> <i>Prevotella sp.</i> <i>Atopobium vaginae</i>	metronidazole 500 mg PO bid x 7d metronidazole gel 1 applicator intravag. daily x 5d

Condition	Microorganisms	Antimicrobial
DERMATOLOGIC		
Mastitis	<i>S. aureus</i> <i>S. pyogenes</i>	cloxacillin 500 mg PO qid x 7d cephalexin 500 mg PO qid x 7d
Tinea Cruris/Pedis (Jock Itch/Athlete's Foot)	Trichophyton	clotrimazole 1% cream – apply bid ketoconazole 2% cream – apply bid
Cellulitis (uncomplicated)	Beta-Hemolytic <i>Strep</i> sp. <i>Staphylococcus</i>	1st line: cephalexin 500 mg PO q6h x 10-14d 2nd line: cloxacillin 500 mg PO q6h x 10-14d or clindamycin 300 mg PO q6-8h x 10-14d, total <1.8 g/d
OPHTHALMOLOGY		
Conjunctivitis (viral)	Adenovirus	None Note: very contagious
Conjunctivitis (bacterial)	<i>S. aureus</i> <i>S. pneumoniae</i> <i>E. Coli</i> <i>H. influenzae</i>	sulfacetamide: 1-2 gtts q2-6h x 7-10d gentamicin: 1-2 gtts q4h x 7-10d erythromycin ointment: apply to lid margins bid-qid, M: 3.5 g tube
Blepharitis	Etiology unclear <i>S. aureus</i> <i>S. epidermidis</i>	erythromycin ophthalmic ointment of no proven benefit If associated with rosacea: doxycycline 100 mg PO bid x 14d

*All doses are adult doses unless otherwise specified

*This chart is not all-encompassing and is non-inclusive of special exceptions (i.e. pregnancy, poor renal clearance, etc.)

Differential Diagnosis of Common Presenting Complaints

Table 1. Differential Diagnosis of Common Presenting Complaints

NAUSEA/ VOMITING	With Abdominal Pain		Without Abdominal Pain/Non GI		
	Relieved by Vomiting	Not Relieved by Vomiting	Headache/Dizziness	No other Symptoms	
	Gastric Outlet Obstruction Small Bowel Obstruction GERD	Gallbladder disease Pancreatitis Myocardial Infarction Hepatitis	Cerebral tumour Migraine Vestibular Increased ICP	Drugs Uremia Pregnancy Metabolic (e.g. hypercalcemia) Gastroparesis (e.g. diabetes) Ketoacidosis	
DYSPHAGIA	Mechanical (Solids)	Motility (Solids and Liquids)	Other		
	Stricture /Cancer Eosinophilic esophagitis Extrinsic compression Schatzki ring/esophageal web Zenker's diverticulum	Achalasia Diffuse esophageal spasm Scleroderma	Foreign Body		
ODYNOPHAGIA	Infection	Inflammation/Ulceration	Drugs	Other	
	Candida Herpes CMV (common only in those who are immunosuppressed)	Caustic damage	Quinidine Iron Vitamin C Antibiotics (e.g. tetracycline)	Radiation	
ABDOMINAL DISTENTION	Fluid		Flatulence	Feces	Other
	Portal HTN	Normal Portal Pressure			
	Cirrhosis Cardiac Failure Hepatic Vein Thrombosis	Cancer esp. ovarian Pancreatitis TB	Functional Bowel Disease Fibre Lactose Chewing gum (e.g. sorbitol, mannitol)	Constipation Colonic obstruction Dysmotility	Pregnancy (fetus) Obesity (fat) Blood Large Tumours (fatal growth)
ACUTE ABDOMINAL PAIN	Upper/Mid-Abdomen	Lower Abdomen			
	Gastroenteritis Cholecystitis Perforated Peptic Ulcer Pancreatitis Small bowel obstruction Mesenteric ischemia Ruptured aortic aneurysm	Gastroenteritis Appendicitis Diverticulitis Crohn's disease Pelvic inflammatory disease Ectopic pregnancy			
CHRONIC/ RECURRENT ABDOMINAL PAIN	Inflammatory	Neoplastic/Vascular	Toxin	Other	
	PUD Biliary colic IBD Chronic pancreatitis	Recurrent bowel obstruction Mesenteric Ischemia Sickle cell anemia	Lead poisoning	Mittelschmerz Endometriosis Porphyria IBS Radiculopathy	
ACUTE DIARRHEA	Invasive	Non-invasive			
	Bacterial <i>Salmonella</i> <i>Campylobacter</i> <i>C. Difficile</i> <i>E. coli</i> (EHEC O157:H7) <i>Shigella</i> <i>Yersinia</i> Protozoal <i>E. histolytica</i> (amebiasis) Strongyloides	Bacterial <i>Saphylococcus aureus</i> <i>B. cereus</i> <i>C. perfringens</i> <i>Vibrio cholera</i> Protozoal <i>Giardia lamblia</i>		Viral Rotavirus Norwalk Cytomegalovirus Drugs Antibiotics Laxatives (Magnesium) Antacids Colchicine Many others	
CHRONIC DIARRHEA	Inflammatory	Secretory	Steatorrhea	Osmotic	
(a) Organic	IBD Ischemic Bowel	Stimulant laxatives Ileal resection (bile salts) Large, villous adenoma Zollinger-Ellison (ZE) Carcinoid Addison's disease VIPoma Parasites	<i>Giardia lamblia</i> Celiac sprue Chronic pancreatitis Diabetes Mellitus	Drugs/Laxatives Lactose intolerance Chewing gum (e.g. sorbitol, mannitol)	
(b) Functional	IBS Constipation (overflow diarrhea) Anal sphincter dysfunction				

Commonly Forgotten Causes of Vomiting

Drugs
Uremia
CNS Disease
Pregnancy

Differential Diagnosis of Abdominal Distention

6 F's
• Fat
• Feces
• Fetus
• Flatus
• Fluid
• Fatal Growth

Acute Upper Abdominal Pain

Remember to consider chest source, e.g. myocardial infarction, pneumonia, dissecting aneurysm.

Intermittent abdominal pain precipitated by eating: think of obstruction (gastric outlet, small bowel); pancreatitis; ischemic bowel.

Obscure But Treatable Causes of Abdominal Pain

Porphyria
Angioedema
Familial Mediterranean Fever
Vasculitis (e.g. polyarteritis nodosa)

Watch out for IBD with bloody diarrhea.

Table 1. Differential Diagnosis of Common Presenting Complaints (continued)

CONSTIPATION			
		Colorectal Cancer Stricture Extrinsic Compression Anal disease Rectocele	Medications (narcotics, antidepressants, calcium channel blockers) Metabolic (diabetes, thyroid, hypercalcemia) Neurological (Parkinson's, multiple sclerosis, stroke) Collagen Vascular Disease (scleroderma, dermatomyositis)
DYSPEPSIA	Common	Uncommon	Rare
	Functional dyspepsia Drug side effect Peptic ulcer GERD	Angina Crohn's disease Cancer Gallstones Aerophagia	<i>Giardia lamblia</i> Malabsorption (celiac sprue)
UPPER GI BLEED	Common	Uncommon	Rare
	Ulcers (<i>H. pylori</i> , ASA, NSAIDs) Esophageal varices Mallory-Weiss tears Erosive esophagitis Erosive gastritis	Tumours Arteriovenous malformation Dieulafoy's lesion Gastric antral vascular ectasia Portal hypertensive gastropathy	Aorto-enteric fistulas Hemobilia
LOWER GI BLEED	Common	Uncommon	Rare
	Diverticulosis Ischemia Angiodysplasia (elderly) Infectious Anorectal (hemorrhoids, fissure, ulcer)	Upper GI bleed Post-polypectomy Radiation colitis IBD	Intussusception Vasculitides Stercoral Ulcer Coagulopathies

Most common cause of constipation is inadequate fibre or fluid intake.

Anatomy Review

Overview of Gastrointestinal Tract

- the gastrointestinal tract runs from mouth to anus ("gum to bum")

Retroperitoneal Structures

SAD PUCKER

Suprarenal glands (aka the adrenal glands)
Aorta/IVC
Duodenum (second to fourth segments)
Pancreas (tail is intraperitoneal)
Ureters
Colon (only the ascending and descending branches)
Kidneys
Esophagus
Rectum

Figure 1. Overview of Gastrointestinal Tract

Figure 2. Arterial Supply of Gastrointestinal Tract

Figure 3. Anatomy of Portal Venous System

Table 2. Summary of Gastrointestinal Tract Structure and Function

Organ	Function	Blood Supply	Innervation	Histology and Structural Features
Esophagus	<ul style="list-style-type: none"> Muscular tube approximately 25 cm long with a diameter of 2 cm Extends from pharynx to the stomach 	<ul style="list-style-type: none"> Arterial: left gastric artery and left inferior phrenic artery Venous: left gastric vein → portal venous system Esophageal veins → azygos vein 	<ul style="list-style-type: none"> Vagal trunks which become the anterior and posterior gastric nerves Thoracic sympathetic trunks via the greater splanchnic nerves 	<ul style="list-style-type: none"> Mucosa: stratified squamous epithelium Submucosa: connective tissue, lymphocytes, plasma cells, nerve cells Muscularis propria: inner circular, outer longitudinal muscle Muscle: upper 1/3 striated muscle, lower 1/3 smooth muscle, separated by transition zone comprised of both
Stomach	<ul style="list-style-type: none"> Chief function is enzymatic digestion Converts mass of food into semiliquid mixture called chyme 	<ul style="list-style-type: none"> Lesser curvature: <ul style="list-style-type: none"> Right and left gastric arteries (from celiac trunk) Greater curvature: <ul style="list-style-type: none"> Right and left gastromental arteries Fundus: short and posterior gastric arteries (from the splenic artery) 	<ul style="list-style-type: none"> Parasympathetic innervation via vagus nerve Sympathetic supply via celiac plexus (from T6-T9) 	<ul style="list-style-type: none"> 4 parts: <ul style="list-style-type: none"> Cardia Fundus Body Pylorus
Duodenum	<ul style="list-style-type: none"> Neutralizes acidic components entering from stomach via secretin and bicarbonate secretion Site of stimulation of bile secretion via CCK release 	<ul style="list-style-type: none"> Branches of celiac and superior mesenteric artery (SMA) 	<ul style="list-style-type: none"> Parasympathetic innervation from the vagus Sympathetic innervations from the greater and lesser splanchnic nerves 	<ul style="list-style-type: none"> 4 parts <ul style="list-style-type: none"> Superior (5 cm) Descending (7-10 cm) Horizontal (6-8 cm) Ascending (5 cm) 1st part is intraperitoneal; rest is retroperitoneal

Table 2. Summary of Gastrointestinal Tract Structure and Function (continued)

Organ	Function	Blood Supply	Innervation	Histology and Structural Features
Jejunum	<ul style="list-style-type: none"> Absorption of salt, water and nutrients (protein, carbohydrates, fat, folic acid, vit B, C, and vit A, D, E, K) 	<ul style="list-style-type: none"> Superior mesenteric artery 	<ul style="list-style-type: none"> Sympathetic fibres (originate from T8-T10) Parasympathetic fibers from the posterior vagal trunk 	<ul style="list-style-type: none"> Deep red colour 2-4 cm in thickness Has a thick and heavy wall Plicae circulares are large, tall and closely packed Has long vasa recta Has little fat in mesentery Has few Peyer Patches
Ileum	<ul style="list-style-type: none"> Absorption of salt, water and nutrients, soluble vitamins (incl. vit B₁₂), bile salts (entero-hepatic circulation) 	<ul style="list-style-type: none"> Superior mesenteric artery 	<ul style="list-style-type: none"> Same as jejunum 	<ul style="list-style-type: none"> When compared to jejunum: <ul style="list-style-type: none"> Paler pink colour 2-3 cm in thickness Has a thin and light wall Plicae circulares are small and sparse Contains more fat in mesentery than jejunum Has many Peyer patches
Large Bowel	<ul style="list-style-type: none"> Absorption of water (5-10% of total water) Bacteria: further digestion of chyme and metabolism of undigested CHO to short chain fatty acids Formation and storage of feces 	<ul style="list-style-type: none"> Branches of superior and inferior mesenteric artery 	<ul style="list-style-type: none"> Parasympathetic innervation from the vagus Sympathetic innervations from the greater and lesser splanchnic nerves 	<ul style="list-style-type: none"> Consists of cecum, colon (ascending, transverse, descending and sigmoid), rectum and anal canal Features include <ul style="list-style-type: none"> Teniae coli Haustra Omental appendices
Liver	<ul style="list-style-type: none"> Glucose homeostasis Plasma protein synthesis Lipid and lipoprotein synthesis Bile acid synthesis and secretion Vitamin A, D, E, K, B₁₂ storage Biotransformation, detoxification Excretion of endogenous and exogenous compounds 	<ul style="list-style-type: none"> 2 sources <ul style="list-style-type: none"> Portal vein (75-80%) Hepatic artery (20-25%) 	<ul style="list-style-type: none"> Sympathetic fibers from the celiac plexus Parasympathetic fibers from the anterior and posterior vagal trunks 	<ul style="list-style-type: none"> Largest internal organ Composed of 4 lobes (left, right, caudate, quadrate) and divided into 8 segments
Biliary Tract	<ul style="list-style-type: none"> Gallbladder functions to store and release bile that is produced in the liver Bile is used to emulsify fat and is composed of cholesterol, lecithin, bile acids and bilirubin Cholecystokinin stimulates gallbladder emptying while trypsin and chymotrypsin inhibit bile release 	<ul style="list-style-type: none"> Gallbladder blood supply: cystic artery 	<ul style="list-style-type: none"> Celiac nerve plexus [carry sympathetic and visceral (pain) afferents] Parasympathetic from the vagus Somatic afferent fibers: right phrenic nerve 	<ul style="list-style-type: none"> Consists of the hepatic ducts (intrahepatic, left, right and common), gallbladder, cystic duct, common bile duct and ampulla of Vater
Pancreas	<ul style="list-style-type: none"> Endocrine function: Islets of Langerhans produce glucagon, insulin and somatostatin (from the alpha, beta and delta cells, respectively) Exocrine function: digestive enzymes are produced including amylase, lipase, trypsin, chymotrypsin and carboxypeptidase 	<ul style="list-style-type: none"> Anterior/posterior superior pancreaticoduodenal artery (from the celiac trunk) Anterior/posterior inferior pancreaticoduodenal artery (from the superior mesenteric artery) Dorsal pancreatic artery (from the splenic artery) Pancreatic veins drain into the portal, splenic and superior mesenteric veins 	<ul style="list-style-type: none"> Vagus and abdominopelvic splanchnic nerves 	<ul style="list-style-type: none"> Generally divided into 4 parts: head (includes uncinate process), neck, body, tail

Remember: Only ileum, not jejunum, can absorb vitamin B₁₂ and bile acids

Esophagus

Dysphagia

Definition

- difficulty swallowing, sensation of food “sticking” after swallowing

Key Questions in Dysphagia

- Difficulty in starting swallowing?
- Associated symptoms? (regurgitation, change in voice pitch, weight loss)
- Solids, liquids or both
- Intermittent or progressive
- History of heartburn
- Change in eating habits/diet

Odynophagia = Pain on swallowing

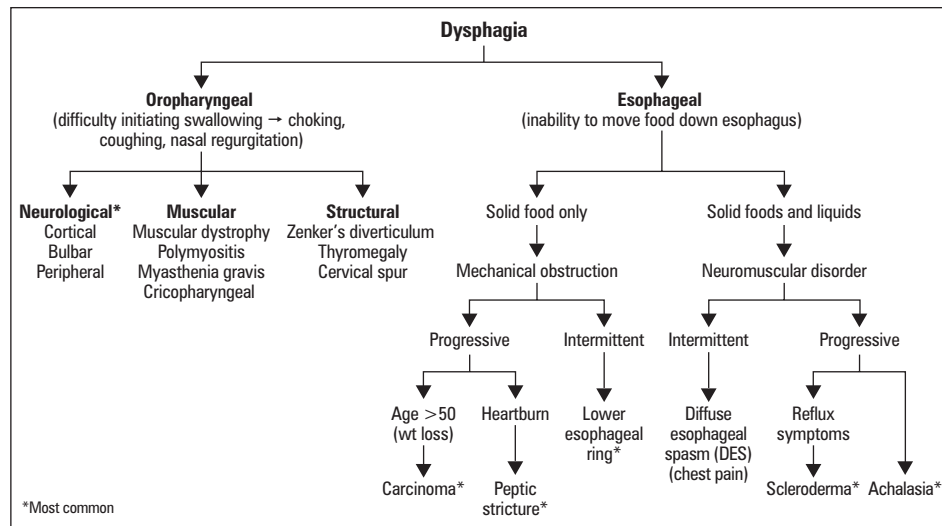

Figure 4. Approach to Dysphagia

Dyspepsia

Definition

- intermittent epigastric discomfort, characteristically develops after eating
- organic disease most likely if age over 55, associated symptoms, taking medications (especially NSAIDs)

Gastroesophageal Reflux Disease (GERD)

Definition

- reflux of gastric contents, especially acid, aborally (toward the mouth) rather than distally into duodenum

Etiology

- inappropriate transient relaxations of lower esophageal sphincter (LES) – most common
- low basal LES tone (especially in scleroderma)
- contributing factors include: delayed esophageal clearance, delayed gastric emptying, increased intra-abdominal pressure
- acid hypersecretion (rare) – Zollinger-Ellison syndrome (gastrin-secreting tumour)
- hiatus hernia worsens reflux, does not cause it (see [General Surgery](#), GS21)

Clinical Features

- “heartburn” (pyrosis) and acid regurgitation (together are 80% sensitive and specific for reflux)
- ± bitter regurgitation, water brash; sensation of a lump in the throat; frequent belching

Key Questions to Ask

Dysphagia
Weight Loss

Foods/substances that Aggravate GERD Symptoms

EtOH
Caffeine
Tobacco
Fatty/fried foods
Chocolate
Peppermint
Spicy foods
Citrus fruit juices

Figure 5. Signs and Symptoms of GERD

Investigations

- usually a clinical diagnosis based on symptom history and relief following a trial of pharmacotherapy (proton pump inhibitor (PPI): symptom relief 80% sensitive for reflux)
- gastroscopy indications:
 - rule out conditions that mimic reflux (e.g. cancer, peptic ulcer, infective esophagitis)
 - distinguish between esophagitis (indicating aggressive treatment) and non-esophagitis reflux disease (NERD – sole goal of treatment is symptom relief)
 - diagnose Barrett's esophagus (requires endoscopic surveillance for cancer)
- esophageal manometry
 - may be done to diagnose abnormal peristalsis and/or decreased LES tone, but cannot detect presence of reflux; indicated before surgical fundoplication to ensure esophagus functional
 - surgical fundoplication more likely to be successful if lower esophageal pressure is diminished; less likely to be successful if abnormal peristalsis
- barium swallow: to assess presence of strictures
- 24-hour pH monitoring: most accurate test but rarely required
 - most useful if PPIs not helpful

Management

- PPIs are most effective therapy, usually need to be continued on maintenance therapy
- on-demand: antacids (MgOH, AlOH, alginate), H₂-blockers or PPIs can be used for NERD
- diet helps symptoms, not the disease; only beneficial lifestyle changes are weight loss (if obese) and elevating the head of bed (if nocturnal symptoms)

Complications

- esophageal stricture disease – scarring can lead to dysphagia (solids)
- ulcer
- bleeding
- Barrett's esophagus (see below) and esophageal adenocarcinoma (0.4% risk per year) – mandates surveillance gastroscopy q2-4yrs

Barrett's Esophagus

Definition

- metaplasia of normal squamous epithelium to abnormal columnar epithelium containing intestinal metaplasia and resulting displacement of the squamocolumnar junction proximal to the gastroesophageal junction

Etiology

- thought to be acquired via long-standing GERD and consequent damage to squamous epithelium

Epidemiology

- in North America and Western Europe, 0.5-2.0% of adults are thought to have Barrett's Esophagus (BE)
- up to 10% of GERD patients will have already developed BE by the time they seek medical attention
- more common in males, >50 yrs, Caucasians and smokers

Pathophysiology

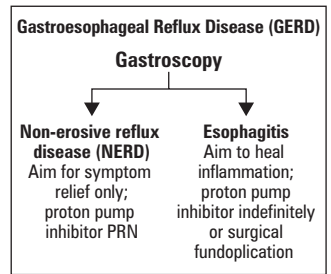

- endoscopy shows erythematous epithelium in distal esophagus; diagnosis of BE relies on biopsy demonstrating the presence of specialized intestinal epithelium of any length within the esophagus
- BE predisposes to premalignant changes in abnormal columnar epithelium, characterized as low- or high-grade dysplasia

Significance

- rate of malignant transformation is approximately 0.4% per year for all BE patients prior to dysplasia
- risk of malignant transformation in high-grade dysplasia is significantly higher; studies have reported a 32-59% transformation rate over 5-8 years of surveillance
- gastric acid secretion increased more often than in reflux without Barrett's

Management

- surveillance gastroscopy with esophageal mucosal biopsy one year after initial diagnosis then every 2-3 years to detect neoplasia
- if dysplasia develops, can be treated non-surgically with endoscopic ablation, endoscopic mucosal resection, radiofrequency, photodynamic therapy or surgery
- acid suppressive therapy with high-dose PPI indefinitely; provides symptom relief
 - may decrease rate of progression to cancer

Esophageal damage from reflux is most severe at first gastroscopy, therefore necessary only once for patients with NERD.

Up to 25% of patients with Barrett's Esophagus do not report symptoms of GERD.

Eosinophilic Esophagitis

Definition

- inflammatory condition with prominence of eosinophils on esophageal biopsy
- most commonly found in children, but increasingly recognized in adults

Etiology

- unknown; may be an “allergic” disorder in children
- cytokines cause edema and fibrosis

Clinical Features

- dysphagia (solids); history often dates back to childhood
- first presentation may be to ER with food bolus impaction

Investigations

- endoscopy may reveal multiple rings or “crepe-paper” appearance
- biopsy necessary to confirm diagnosis

Management

- corticosteroid (e.g. fluticasone) spray – swallowed not inhaled
- leukotriene B4 inhibitors (e.g. Montelukast)

Complications

- progressive narrowing
- increased risk of perforation with bougienage

Esophageal Motor Disorders

Symptoms

- dysphagia with solids and liquids
- chest pain (in some disorders)

Diagnosis

- esophageal motility study (esophageal manometry)
- barium swallow sometimes helpful

Causes (Table 3)

- idiopathic
- achalasia (painless)
- scleroderma (painless)
- diabetes
- diffuse esophageal spasm (DES) – rare, can be difficult to diagnose because intermittent

Table 3. Esophageal Motor Disorders

Disorder	Achalasia	Scleroderma	Diffuse Esophageal Spasm (DES)
Definition	<ul style="list-style-type: none"> • Failure of smooth muscle relaxation at LES • Progressive loss of peristaltic function 	<ul style="list-style-type: none"> • See <u>Rheumatology</u>, RH11 • Disease of collagen 	<ul style="list-style-type: none"> • Normal peristalsis interspersed with frequent, repetitive, spontaneous, high pressure, non-peristaltic waves (tertiary peristalsis)
Etiology	<ul style="list-style-type: none"> • Usually idiopathic • Incomplete relaxation of LES with swallowing • High LES resting pressure in most (if 2° to cancer, considered pseudo-achalasia) • Chagas disease (<i>T. cruzi</i>) 	<ul style="list-style-type: none"> • Dysphagia: can be due to reflux or dysmotility, usually both 	<ul style="list-style-type: none"> • Unknown
Pathophysiology	<ul style="list-style-type: none"> • Unknown (increased impaired inhibition related to decreased NO release) 	<ul style="list-style-type: none"> • Blood vessel damage → intramural neuronal dysfunction → distal esophageal muscle weakening → aperistalsis and loss of LES tone → reflux → stricture → dysphagia 	<ul style="list-style-type: none"> • Unknown

Table 3. Esophageal Motor Disorders (continued)

Disorder	Achalasia	Scleroderma	Diffuse Esophageal Spasm (DES)
Diagnosis	<ul style="list-style-type: none"> Chest x-ray: no air in stomach, with dilated esophagus Barium studies: esophagus terminates in narrowing at the sphincter, giving a "bird's beak" appearance Endoscopy to r/o malignancy Motility study for definitive diagnosis 	<ul style="list-style-type: none"> Clinical features of scleroderma Manometry: decreased pressure in LES, decreased peristalsis in body of esophagus 	<ul style="list-style-type: none"> Barium x-ray: "Corkscrew pattern"
Treatment	<ul style="list-style-type: none"> Dilatation of LES with balloon, \pm GERD prophylaxis, 50% good response, can repeat, risk of perforation (5%) Injection of botulinum toxin into LES (temporary) Surgery (myomectomy) 	<ul style="list-style-type: none"> Medical: aggressive GERD therapy (PPIs bid) Surgery: anti-reflux surgery (gastroplasty, last resort) 	<ul style="list-style-type: none"> Reassurance not cardiac pain Medical: nitrates, calcium channel blockers, anticholinergics have variable benefit Surgical: long esophageal myotomy if unresponsive to above treatment (rarely helpful); balloon dilatation

Esophageal Diverticula

Definition

- outpouchings of one or more layers of GI tract

Clinical Features

- commonly associated with motility disorders
- dysphagia, regurgitation, retrosternal pain, intermittent vomiting, may be asymptomatic

Classification

- classified according to location
 - pharyngoesophageal (Zenker's) diverticulum
 - most frequent form of esophageal diverticulum
 - posterior pharyngeal outpouching most often on the left side, above cricopharyngeal muscle and below the inferior pharyngeal constrictor muscle
 - symptoms: dysphagia, regurgitation of undigested food, halitosis
 - treatment: endoscopic or surgical myotomy of cricopharyngeal muscle \pm surgical excision of sac
 - mid-esophageal diverticulum
 - secondary to mediastinal inflammation, motor disorders
 - usually asymptomatic; no treatment required
 - just proximal to LES (pulsatile type)
 - usually associated with motor disorders
 - usually asymptomatic; no treatment required

Peptic Stricture (From Esophagitis)

- presents as intermittent or progressive dysphagia in face of reflux symptoms, but reflux symptoms may disappear with progression
- diagnose with barium study or endoscopy

Treatment

- endoscopic dilatation and indefinite PPI
- anti-reflux surgery if above unsuccessful

Esophageal Cancer

- see General Surgery, GS14

Webs and Rings

- web = partial occlusion (upper esophagus)
- ring = circumferential narrowing (lower esophagus)

Clinical Features

- asymptomatic with lumen diameter >12 mm, provided peristalsis is normal
- dysphagia with large food boluses
- Plummer-Vinson or Patterson-Kelly syndrome
 - upper esophageal web with iron deficiency, plus cheilosis (dry scaling and fissuring of the lips) and koilonychia (concave outer nail surface)
 - usually in middle-aged females (>40 years)
 - elevated risk of hypopharyngeal carcinoma
- Schatzki's ring
 - mucosal ring at squamo-columnar junction above a hiatus hernia
 - causes intermittent dysphagia with solids
 - treatment involves disrupting ring with endoscopic bougie

Infectious Esophagitis

Definition

- severe mucosal inflammation and ulceration as a result of viral or fungal infection

Risk Factors

- diabetes
- malignancy (chemotherapeutic agents)
- immunocompromised states

Symptoms

- characteristically odynophagia, less often dysphagia
- diagnosis is via endoscopic visualization and biopsy

Treatment

- *Candida* (most common): nystatin swish and swallow, ketoconazole, fluconazole
- Herpes (second most common): often self-limiting; acyclovir, vancyclovir, famciclovir
- CMV: IV ganciclovir, famciclovir

Stomach and Duodenum

Gastritis

Definition

- defined histologically: inflammation of the stomach mucosa

Etiology

- most common causes (see Table 4)
 - *Helicobacter pylori* infection
 - drugs: NSAIDs
 - physiological stress-related mucosal changes (in ICU)
 - other (rare): granulomatous, lymphocytic, eosinophilic, infectious (TB, syphilis, CMV)
- Crohn's disease

Clinical Features

- only erosive gastritis presents with symptoms (bleeding)
- non-erosive gastritis is asymptomatic
- erosions may be present on endoscopy

Management

- determined by underlying etiology (see below)

Table 4. Updated Sydney Classification of Gastritis

Type	Common Etiology
Non-atrophic Multifocal	<i>Helicobacter pylori</i>
Lymphocytic	Celiac disease
Eosinophilic	Allergy
Granulomatous	TB, syphilis, Crohn's disease, sarcoidosis

Gastric Acid Secretion

Stomach

- primary function is mechanical grinding of food facilitating early enzymatic digestion into chyme and propulsion into duodenum

Table 5. Cells of the Gastric Mucosa

Cell Type	Secretory Product	Important Notes
Parietal cells	Gastric acid (HCl) Intrinsic factor	Stimulated by histamine, ACh, gastrin
Chief cells	Pepsinogen	Stimulated by vagal input and local acid
G-cells	Gastrin	Stimulates H ⁺ production from parietal cells
Superficial epithelial cells	Mucus, HCO ₃ ⁻	Protect gastric mucosa

Figure 6. Stimulation of H⁺ Secretion from the Parietal Cell

Peptic Ulcer Disease (PUD)

Definition

- erosion (superficial to the muscularis mucosa, thus no scarring) or ulcer (penetrates the muscularis mucosa and can result in scarring)

Etiology

Table 6. Etiology of Peptic Ulcer Disease

	Duodenal	Gastric
<i>H. pylori</i> infection	90%	60%
NSAIDs	7%	35%
Physiologic stress-induced	<3%	<5%
Zollinger-Ellison (ZE) syndrome	<1%	<1%

Gastric vs. Duodenal Ulcers
Gastric ulcers must always be biopsied to rule out malignancies. Duodenal ulcers are rarely malignant.

- NSAID negative, *H. pylori* negative ulcers becoming more commonly recognized
- others: CMV, ischemic, idiopathic
- alcohol: damages gastric mucosa but only rarely causes ulcers
- peptic ulcer associated with cirrhosis of liver, COPD, chronic renal failure

Clinical Features

- dyspepsia: most common presenting symptom
 - only 20% of patients with dyspepsia have ulcers
- may present with complications
 - bleeding 10% (severe if from gastroduodenal artery); see *Bleeding Peptic Ulcer*, G27
 - perforation 2% (usually anterior ulcers)
 - gastric outlet obstruction 2%
 - penetration (posterior) 2%; may also cause pancreatitis

- duodenal ulcers present with 6 classical features:
 - epigastric pain; may localize to tip of xiphoid
 - burning
 - develops 1-3 hours after meals
 - relieved by eating and antacids
 - interrupts sleep
 - periodicity (tends to occur in clusters over weeks with subsequent periods of remission)
- gastric ulcers have more atypical symptoms; a biopsy is necessary to exclude malignancy

Investigations

- endoscopy (most accurate)
- upper GI series
- *H. pylori* tests (see Table 7)
- fasting serum gastrin measurement if Zollinger-Ellison (ZE) syndrome suspected

Treatment

- specific management depends on etiology; refer to *H. pylori*, NSAID and Stress-Induced Ulceration sections (see below)
- eradicate *H. pylori* if present, chief advantage is to lower ulcer recurrence rate
- stop NSAIDs if possible
- start PPI: inhibits parietal cell H^+/K^+ -ATPase pump which secretes acid
 - heals most ulcers, even if NSAIDs are continued
- other meds (e.g. histamine H_2 -antagonists) less effective
- discontinue tobacco
- no diet modifications required but some people have fewer symptoms if they avoid caffeine, alcohol and spices

Approach to PUD

1. Stop NSAIDs
2. Acid neutralization
3. *H. pylori* eradication
4. Quit smoking

Cigarette Smoking and PUD

- Increased risk of ulcer
- Increased risk of complications
- Increased chance of death from ulcer
- Impairs healing

H. pylori-Induced Ulceration

Pathophysiology

- *H. pylori*: Gram-negative flagellated rod that resides on but does not invade the gastric mucosa
- acid secreted by parietal cell (stimulated by vagal acetylcholine, gastrin, histamine) necessary for most ulcers
- mucosal defenses moderated by PGE_2 and blood flow, mucus, etc.
- theories of how *H. pylori* causes ulcers:
 - toxin production: causes gastric mucosal inflammation and necrosis
 - interference with acid regulation: *H. pylori* blocks G cells in antrum from sensing luminal acid → increased serum gastrin → increased gastric acid → ulcer

Epidemiology

- *H. pylori* is found in about 20% of all Canadians
 - highest prevalence in those raised during 1930s
- infection most commonly acquired in childhood, presumably by fecal-oral route
- high prevalence in developing countries, low socioeconomic status (poor sanitation and crowding)

Symptoms

- non-erosive gastritis in 100% of patients but this does not cause symptoms
- peptic ulcer in 15% of patients, gastric malignancy (cancer and mucosal associated lymphomatous tissue lymphoma [MALT lymphoma] in 0.5% of patients)
- most are asymptomatic but still worthwhile eradicating to lower future risk of peptic ulcer/ gastric malignancy and prevent spread to others (mostly children <5 years of age)

Investigations

Table 7. Diagnosis of *H. pylori* Infection

Test	Sensitivity	Specificity	Comments
Non-invasive Tests			
Urea breath test	90-100%	89-100%	Affected by PPI therapy (false negatives)
Serology	88-99%	89-95%	Can remain positive after treatment
Invasive Tests (require endoscopy)			
Histology	93-99%	95-99%	Gold standard; affected by PPI therapy (false negatives)
Rapid urease test (on biopsy)	89-98%	93-100%	Rapid
Microbiology culture	98%	95-100%	Research only

Treatment: *H. pylori* Eradication

- triple therapy for 7-14 days (Hp-Pac®): PPI BID + amoxicillin 1 g BID + clarithromycin 500 mg BID
 - 90% success rate
- quadruple therapy for 10-14 days: PPI BID + tripotassium dicitratobismuthate 120 mg qid + tetracycline 500 mg qid + metronidazole 250 mg qid
 - only recommended as first line therapy if resistance to clarithromycin or metronidazole is high, or in patients with recent or repeated exposure to these drugs
- sequential therapy
 - days 1-5: PPI bid + amoxicillin 1 g BID
 - days 6-10: PPI bid + clarithromycin 500 mg BID + metronidazole or tinidazole 500 mg BID
- 5-15% of cases are resistant to all known therapies

NSAID-Induced Ulceration

- NSAIDs cause gastric mucosal petechiae in virtually all users, erosions in most users, ulcers in some users (25%)
 - erosions bleed, but usually only ulcers cause significant clinical problems
- most NSAID ulcers are clinically silent: dyspepsia is as common in patients with ulcers as in patients without ulcers; NSAID-induced ulcers characteristically present with complications (bleeding, perforation, obstruction)
- NSAIDs more commonly cause gastric ulcers than duodenal ulcers
- may exacerbate underlying duodenal ulcer disease

Pathophysiology

- direct: petechiae and erosions are due to local effect of drug on gastric mucosa
- indirect: systemic NSAID effect
 - NSAIDs inhibit mucosal cyclooxygenase, leading to decreased synthesis of protective prostaglandins, thus leading to ulcers

Risk Factors For NSAID Causing Peptic Ulcer

- age
- previous peptic ulcers/UGIB
- high dose of NSAID/multiple NSAIDs being taken
- concomitant corticosteroid use
- concomitant cardiovascular disease/other significant diseases

Treatment

- prophylactic cytoprotective therapy (PPI) is recommended if any of the above risk factors exist concomitantly with ASA/NSAID use
- lower NSAID dose, or stop all together and replace with acetaminophen
- combine NSAID with PPI or misoprostol
- enteric coating of aspirin (ECASA) provides minor benefit since this decreases incidence of erosion, not incidence of ulceration

If at high risk for development of ulcers, prophylaxis with PPI indicated

The David Y Graham Lecture: Use of Nonsteroidal Antiinflammatory Drugs (NSAID) in a COX-2 Restricted Environment

Am J Gastroenterol 2008; 103:221-227
This short article reviews the current understanding of NSAID risks, emphasizing (1) with the possible exception of naproxen, all NSAIDs increase cardiovascular/cerebrovascular risk, especially the COX-2 specific inhibitors (2) low-dose aspirin, now used widely to decrease these risks, increases the likelihood of upper GI tract bleeding and may not abrogate the cardiovascular risk of NSAIDs (3) clopidogrel is no safer than aspirin in patients with high risk of upper GI tract bleeding (4) add a proton pump inhibitor to NSAID if there is an increased risk of upper GI events.

Stress-Induced Ulceration**Definition**

- ulceration or erosion in the upper GI tract of ill patients, usually in ICU
- lesions most commonly in fundus of stomach

Pathophysiology

- unclear: likely involves ischemia; may occur with CNS disease, acid hypersecretion
- physiological stress (e.g. fever, severe illness, complex post-op course) causes ulcers and erosions

Risk Factors

- mechanical ventilation
- anti-coagulation
- multi-organ failure
- septicemia
- severe surgery/trauma
- CNS injury ("Cushing's ulcers")
- burns involving more than 35% of body surface

Clinical Features

- UGIB (see *Upper Gastrointestinal Bleeding*, G26)
- painless

Treatment

- prophylaxis with gastric acid suppressants (H_2 -blockers or PPI) decreases risk of UGIB, but may increase risk of pneumonia
- treatment same as for bleeding peptic ulcer but often less successful

Gastric Cancer

- see *General Surgery*, GS17

Small and Large Bowel**Classification of Diarrhea****Definition**

- clinically, diarrhea defined as stools that are looser and/or more frequent than normal; or 24 hr stool weight >200 g (physiological definition, less useful clinically)

Classification

- small volume (tablespoons of stool; typical of colonic diseases) versus large volume (>1/2 cup stool; typical of small bowel diseases)
- acute vs. chronic
- watery (bowel disease) vs. steatorrhea
- secretory (diarrhea persists with fasting) vs. osmotic (diarrhea stops with fasting)

Table 8. Classification of Diarrhea

Acute	Chronic	
Infectious	Functional	Neoplastic
• Bacterial	• IBS	• Medullary thyroid carcinoma
• Viral	• Constipation with overflow diarrhea	• Gastrinoma
• Parasitic	Inflammatory	• VIPoma
• Fungal (rare)	• IBD (UC, CD)	• Small bowel lymphoma
Iatrogenic	• Microscopic/collagenous colitis	• Carcinoid tumours
• Drugs	Maldigestion/malabsorption	• Colorectal cancer
• Surgery	• Pancreatic disease (chronic pancreatitis, autoimmune pancreatitis, malignancy)	• Large villous adenoma of rectum
• Radiation	• Celiac disease	Iatrogenic
Osmotic agents	• Short bowel syndrome	• Drugs, alcohol, caffeine
• Lactose	• Small intestinal bacterial overgrowth	• Surgery
• Sugars (sorbitol, mannitol, xylitol etc.)	Metabolic	• Radiation
• Laxative abuse	• Hyperthyroidism	• Laxative abuse
	• Addison's disease	Miscellaneous
	• Uremia	• Chronic mesenteric ischemia
	• Cystic fibrosis	• Incontinence

**Acute Diarrhea****Definition**

- passage of frequent unformed stools for <14 days

Etiology

- most commonly due to infections
- most infections are self-limiting and resolve in 7 days

Risk Factors

- food (seafood, chicken, turkey, eggs, beef)
- medications: antibiotics, laxatives
- others: high risk sexual activity, infectious outbreaks, family history (IBD)

Classification

- broadly divided and classified into inflammatory and non-inflammatory diarrhea
- mechanisms:
 - stimulation of intestinal water secretion and inhibition of water absorption (i.e. secretory problem)
 - in inflammatory diarrhea, organisms and cytotoxins invade mucosa, killing mucosal cells, further perpetuating the diarrhea

Table 9. Classification of Acute Diarrhea

	Inflammatory	Non-inflammatory
Definition	Disruption of intestinal mucosa	No disruption of intestinal mucosa
Site	Small bowel ± colon	Usually small intestine
Sigmoidoscopy	Usually abnormal mucosa seen	Usually normal
Symptoms	Bloody (not always) Small volume, high frequency Often lower abdominal cramping with urgency ± tenesmus May have fever ± shock	Watery, little or no blood Large volume Upper/periumbilical pain/cramp ± shock
Investigations	Fecal WBC and RBC positive	Fecal WBC negative
Etiology	Infectious <ul style="list-style-type: none"> • Bacterial <ul style="list-style-type: none"> <i>Shigella</i> <i>Salmonella typhi</i> <i>Campylobacter</i> <i>Yersinia</i> <i>E. coli</i> (EHEC 0157:H7) <i>C. difficile</i> • Protozoal <ul style="list-style-type: none"> <i>E. histolytica</i> (amebiasis) <i>Strongyloides</i> Drugs <ul style="list-style-type: none"> NSAIDs Inflammatory bowel disease 	Infectious <ul style="list-style-type: none"> • Bacterial <ul style="list-style-type: none"> <i>Salmonella enteritidis</i> <i>S. aureus</i> <i>B. cereus</i> <i>C. perfringens</i> <i>E. coli</i> (ETEC, EPEC) <i>Vibrio cholerae</i> • Protozoal <ul style="list-style-type: none"> <i>Giardia lamblia</i> • Viral <ul style="list-style-type: none"> Rotavirus Norwalk CMV Drugs <ul style="list-style-type: none"> Antacids (Mg: Makes you Go) Antibiotics Laxatives, lactulose Colchicine
Differential Diagnosis	Acute presentation of a chronic diarrheal condition	Chronic diarrheal illness
Significance	Higher yield with stool C&S Can progress to life-threatening megacolon, perforation, hemorrhage	Lower yield with stool C&S Chief life-threatening problem is fluid depletion and electrolyte disturbances

Investigations

- stool cultures/microscopy (C&S/O&P)
 - C&S only tests *Campylobacter*, *Salmonella*, *Shigella*, *E. Coli*
 - ♦ other organisms must be ordered separately
- flexible sigmoidoscopy: useful if inflammatory diarrhea suspected
 - biopsies are the most useful method of distinguishing idiopathic IBD (Crohn's disease and ulcerative colitis) from infectious colitis or acute self-limited colitis
- *C. difficile* toxin: indicated when recent/remote antibiotic use, hospitalization, nursing home or recent chemotherapy

Treatment

- fluid and electrolyte replacement orally in most cases, intravenous if severe, extremes of age and coma
- anti-diarrheals
 - ant motility agents: diphenoxylate, loperamide (Imodium®); contraindicated in mucosal inflammation
 - ♦ side effects: abdominal cramps, toxic megacolon
 - absorbants: kaolin/pectin (Kaopectate®), methylcellulose, activated attapulgite
 - ♦ act by absorbing intestinal toxins/micro-organisms, or by coating intestinal mucosa
 - ♦ much less effective than ant motility agents
 - modifiers of fluid transport: bismuth subsalicylate (Pepto-Bismol®) may be helpful
- antibiotics: rarely indicated
 - risks
 - ♦ prolonged excretion of enteric pathogen (especially *Salmonella*)
 - ♦ drug side effects (including *C. difficile* infection)
 - ♦ development of resistant strains

Useful Questions in Acute Diarrhea

Those Fads Wilt

Travel
Homosexual contacts
Outbreaks
Seafood
Extra-intestinal signs of IBD
Family history
Antibiotics
Diet
Steatorrhea
Weight loss
Immunosuppressed
Laxatives
Tumour history

Infectious Causes of Inflammatory Diarrhea

Think "CaSaDiff Coli-EhShY"

Campylobacter
Salmonella
C. difficile
E. coli (EHEC 0157:H7)
E. histolytica
Shigella
Yersinia

Stool Osmotic Gap

Normally, and in secretory diarrhea, stool osmolality (as measured by freezing point depression; almost always about 290 mOsm/kg) is the same as calculated stool osmolality (2 x stool (Na + K)). In osmotic diarrhea, measured stool osmolality > calculated stool osmolality.

S. typhi has a rose spot rash (transient maculopapular rash on anterior thorax, upper abdomen), and a prodrome of high fever, bradycardia, headache and abdominal pain. Diarrhea is not the initial presentation.

- indications for antimicrobial agents in acute diarrhea:
 - ♦ septicemia
 - ♦ prolonged fever with fecal blood or leukocytes
 - ♦ clearly indicated: *Shigella*, *V. cholerae*, *C. difficile*, Traveller's Diarrhea (Enterotoxigenic *E. coli* (ETEC)), *Giardia*, *Entamoeba histolytica*, *Cyclospora*
 - ♦ situational: *Salmonella*, *Campylobacter*, *Yersinia*, non-enterotoxigenic *E. coli*
 - ♦ *Salmonella*: always treat *Salmonella typhi* (typhoid or enteric fever); treat other *Salmonella* only if there is underlying immunodeficiency, hemolytic anemia, extremes of age, aneurysms, prosthetic valve grafts/joints

Traveller's Diarrhea

- see [Infectious Diseases](#), ID18

Chronic Diarrhea

Definition

- passage of frequent unformed stool for >14 days
- differential is similar to that of acute diarrhea, except that the majority of cases are non-infectious

Etiology/Classification

- see [Classification of Diarrhea](#), G14

Investigations

- guided by history
- stool analysis for: *C. difficile* toxin, C&S, O&P ± fecal fat, WBC
- blood for: CBC, chemistry, CRP, TSH, celiac serology (tTG, protein electrophoresis)
- colonoscopy and ileoscopy with biopsy
- small bowel biopsy
- upper GI endoscopy with duodenal biopsy
- wireless small bowel endoscopy capsule (last resort – very costly)
- trial of lactose free diet
 - may delay diagnosis of IBD and celiac disease

Maldigestion and Malabsorption

Definition

- **maldigestion**: inability to break down large molecules in the lumen of the intestine into their component small molecules
- **malabsorption**: inability to transport molecules across the intestinal mucosa to the circulation
- **malassimilation**: encompasses both maldigestion and malabsorption

Etiology

- **maldigestion**
 - inadequate mixing of food with enzymes (e.g. post-gastrectomy)
 - pancreatic exocrine deficiency
 - primary diseases of the pancreas (e.g. cystic fibrosis, pancreatitis, cancer)
 - bile salt deficiency
 - ♦ terminal ileal disease (impaired recycling), bacterial overgrowth (deconjugation of bile salts), rarely liver disease (cholestatic)
 - specific enzyme deficiencies (e.g. lactase)
- **malabsorption**
 - inadequate absorptive surface
 - immunologic or allergic injury (e.g. celiac disease)
 - ♦ infections/infestations (e.g. Whipple's disease, giardiasis)
 - ♦ infiltration (e.g. lymphoma, amyloidosis)
 - ♦ fibrosis (e.g. systemic sclerosis, radiation enteritis)
 - ♦ bowel resection
 - ♦ extensive Crohn's disease
- drug-induced
 - cholestyramine, ethanol, neomycin, tetracycline and other antibiotics
- endocrine
 - e.g. diabetes (complex pathogenesis)

Clinical Features

- symptoms usually vague unless disease is severe
- weight loss, diarrhea, steatorrhea, weakness, fatigue
- manifestations of malabsorption/deficiency (see Table 10)

Table 10. Absorption of Nutrients and Fat Soluble Vitamins

Deficiency	Absorption	Signs and Symptoms	Investigations
Iron	Duodenum, upper jejunum	Hypochromic, microcytic anemia, glossitis, koilonychia (spoon nails), pica	↓ Hb, ↓ serum Fe, ↓ serum ferritin
Calcium	Duodenum, upper jejunum (binds to Ca binding-protein in cells; levels increased by Vit D)	Metabolic bone disease, may get tetany and paresthesias if serum calcium falls (see Endocrinology , E40)	↓ serum Ca, serum Mg, and ↑ ALP evaluate for ↓ bone mineralization radiographically (DEXA)
Folic acid	Jejunum	Megaloblastic anemia, glossitis, ↓ red cell folate (but may see ↑ folic acid with bacterial overgrowth)	↓ serum folic acid
Vitamin B₁₂	B ₁₂ ingested and bound to R proteins mainly from salivary glands; stomach secretes Intrinsic Factor (IF) in acidic medium; in basic medium, proteases from the pancreas cleave R protein and B ₁₂ -IF complex forms, protecting B ₁₂ from further protease attack; B ₁₂ absorbed in ileum and binds to transcobalamin (TC)	Subacute combined degeneration of the spinal cord, peripheral/optic neuropathy, dementia, megaloblastic anemia, glossitis	Differentiate causes by Schilling test (see Table 11)
Carbohydrate	Complex polysaccharides hydrolyzed to oligosaccharides and disaccharides by salivary and pancreatic enzymes Monosaccharides absorbed in duodenum/jejunum	Generalized malnutrition, weight loss, flatus and diarrhea	Hydrogen breath test Trial of CHO-restricted diet D-xylose test
Protein	Digestion at stomach, brush border, and inside cell Absorption occurs primarily in the jejunum	General malnutrition and weight loss, amenorrhea and ↓ libido if severe	↓ serum albumin (low sensitivity)
Fat	Lipase, colipase, phospholipase A (pancreatic enzymes) and bile salts needed for digestion Products of lipolysis form micelles which solubilize fat and aid in absorption Fatty acids diffuse into cell cytoplasm	Generalized malnutrition, weight loss and diarrhea Foul-smelling feces + gas (steatorrhea)	Small bowel biopsy MRCP, ERCP, pancreatic function tests Quantitative stool fat test (72 hr) (Sudan stain of stool) (C-triolein breath test)
Vitamin A	From plants	Night blindness Dry skin Keratomalacia	
Vitamin D	Skin (via UV light) or diet	Osteomalacia in adults Rickets in children	
Vitamin E	From food	Retinopathy, neurological problems	
Vitamin K	Synthesized by intestinal flora ↑ risk of deficiency after prolonged use of broad spectrum antibiotics and/or starvation	Prolonged INR causes bleeding	

Investigations

- 72 hour stool collection (weight, fat content)
- serum carotene, folate, Ca, Mg, vitamin B₁₂, albumin, ferritin, serum iron solution, INR/PTT
- stool fat globules on fecal smear (rarely used)
- other tests specific for etiology (e.g. CT scan/MRI to visualize pancreas)
- trial of therapy with pancreatic enzymes

Treatment

- dependent on underlying etiology

Table 11. Schilling Test

Part I	<ul style="list-style-type: none"> • 1000 mcg B₁₂ s.c. injection to saturate liver stores • Standard dose radioactively labelled B₁₂ PO • 48hr urine collection; measure amount labelled B₁₂; normal ≥10% of oral dose
Part II	<ul style="list-style-type: none"> • If urine B₁₂ low, repeat part I giving intrinsic factor with oral radiolabelled B₁₂
Interpretation	<ul style="list-style-type: none"> • If part II is normal, diagnosis pernicious anemia • If part II remains low, options are <ol style="list-style-type: none"> 1) Repeat part II, on day 6 and 7 of a 7-day course tetracycline 500 mg PO bid; if Schilling normalizes diagnosis bacterial overgrowth 2) Repeat part II adding pancreatic enzymes; if Schilling normalizes, diagnosis pancreatic insufficiency 3) If test remains low after 1) and 2), consider R protein deficiency, ileal receptor disease, severe extensive ileal Crohn's disease or failure to obtain history of ileal resection

Fat Soluble Vitamins: ADEK

Vitamin K dependent coagulation factors: II, VII, IX, X, protein C, protein S
Think: "1972 Olympics Canada versus the Soviet Union".

**Gluten found in "BROW"**

Barley

Rye

Oats (controversial)

Wheat

Celiac Disease (Gluten Enteropathy/Sprue)

Definition

- abnormal small intestine mucosa due to intestinal reaction to gliadin, a component of gluten

Etiology

- only autoimmune disease in which antigen (alpha-gliadin) is recognized
- associated with other autoimmune diseases, especially thyroid disease
- gluten, a protein in cereal grains, broken down to gliadin, is toxic factor
- HLA-DQ2 (chromosome 6) found in 80-90% of patients compared with 20% in general population; also associated with HLA-DQ8

Epidemiology

- more common in women
- family history: 15% of first-degree relatives
- may present any time from infancy (when cereals introduced) to elderly
- peak presentation in infancy and old age

Clinical Features

- classically: diarrhea, weight loss, anemia, symptoms of vitamin/mineral deficiency, failure to thrive; now more commonly bloating, gas, iron deficiency
- improves with gluten-free diet, deteriorates when gluten reintroduced
- disease is usually most severe in proximal bowel
 - thus iron, calcium and folic acid deficiency more common than vitamin B₁₂ deficiency
- gluten enteropathy may be associated with dermatitis herpetiformis skin eruption, epilepsy, myopathy, depression, paranoia, infertility, bone fractures/metabolic bone disease

Investigations

- small bowel mucosal biopsy (usually duodenum) is usually diagnostic:
 - villous atrophy and crypt hyperplasia
 - increased number of plasma cells and lymphocytes in lamina propria
 - similar pathology in: small bowel overgrowth, Crohn's, lymphoma, Giardia, HIV
- consider CT enterography to visualize small bowel to rule out lymphoma
- evidence of malabsorption (localized or generalized)
 - steatorrhea
 - low levels of ferritin/iron saturation, Ca, Fe, albumin, cholesterol, carotene, B₁₂ absorption
- improvement with a gluten-free diet; should not be started before anti-TTG and biopsy
- serological tests
 - serum anti-TTG antibody, IgA, is 90-98% sensitive, 94-97% specific
 - IgA deficient patients have false-negative anti-TTG
 - ♦ thus measure serum IgA concomitantly (via serum protein electrophoresis)
- fecal fat >7% over 72 hrs

Treatment

- dietary counselling
 - gluten free diet: avoid barley, rye, wheat
 - ♦ oats allowed if not contaminated by other grains
 - rice and corn flour are acceptable
 - iron, folate supplementation (with supplementation of other vitamins as needed)
- if disappointing response to diet, consider:
 - incorrect diagnosis
 - non-adherence to gluten-free diet
 - unsuspected concurrent disease (e.g. microscopic colitis, pancreatic insufficiency)
 - development of intestinal (enteropathy-associated T-cell) lymphoma (abdominal pain, weight loss, palpable mass)
 - development of diffuse intestinal ulceration, characterized by aberrant intraepithelial T-cell population (precursor to lymphoma)

Prognosis

- associated with increased risk of lymphoma, carcinoma (e.g. small bowel and colon)
- risk of malignancy may be lowered by dietary gluten restriction

Gluten Microchallenge with Wheat-based Starch Hydrolysates in Celiac Disease Patients

Aliment Pharmacol Ther 2008; 28:1240-8

Study: Randomized, placebo-controlled, prospective study with 24 week follow-up.

Participants: 90 patients with celiac disease in remission.

Intervention: Patients either received glucose syrups, maltodextrins or placebo.

Primary Outcome: Small bowel mucosal morphology and inflammation, symptoms, celiac serology and malabsorption.

Results: There were significant differences on deleterious effects in small-bowel morphology or inflammation, gastrointestinal symptoms, serology or malabsorption parameters after 24 weeks compared to the placebo group.

Conclusion: Celiac patients can safely continue to consume wheat-based starch hydrolysates, glucose syrups and maltodextrins.

Bacterial Small Bowel Overgrowth

Definition

- syndrome caused by proliferation of bacteria in small bowel to concentrations $>10^4$ bacteria/mL of bowel tissue

Etiology

- anatomic factors
 - jejunal diverticulae
 - surgical blind loop
 - fistulae
 - strictures (Crohn's disease, radiation injury)
 - obstruction
 - surgical resection of the ileocecal valve
- decreased motility
 - scleroderma
 - diabetes
 - hypothyroid
 - intestinal pseudo-obstruction
- achlorhydria (often iatrogenic): lack of gastric acid production
- multifactorial (controversial) in chronic pancreatitis, celiac disease, irritable bowel syndrome
- described in elderly patients without known etiology

Clinical Features

- steatorrhea: bacteria deconjugate bile salts impairing micellar lipid formation
- diarrhea: bowel mucosa damaged by bacterial products, impairing absorption; altered gut motility, free bile acids stimulate colon water secretion
- megaloblastic anemia due to vitamin B₁₂ malabsorption (bacteria take up B₁₂)
- bloating, flatulence
- may be asymptomatic

Investigations

- gold standard: mixed bacterial cultures of $>10^4$ CFU/mL from the jejunum (via aspiration)
- 72-hour fecal fat collection
- bile acid breath tests
- positive three stage Schilling test if done before and after treatment can be diagnostic (see Table 11)
- low serum B₁₂, high serum folate (folate synthesized by GI bacteria)
- CT enterography to look for underlying cause
- consider small bowel biopsy to rule out primary mucosal disease as cause of malabsorption

Treatment

- treat underlying etiology if possible (e.g. prokinetic agents for small bowel motility disorder, surgery or balloon dilatation for strictures)
- correct nutritional deficiencies, especially deficiencies of vitamins A, D, E, K, B₁₂
- often need to restrict lactose since underlying disease often causes lactose intolerance
- eradicate bacteria: 10-14 day trial of antibiotics (best if based on culture results)
 - e.g. amoxicillin + clavulanic acid, norfloxacin, neomycin
- patients may need to be treated with intermittent or continuous antibiotics indefinitely
 - rotate antibiotics to decrease development of resistance
- discontinue acid-reducing agents if possible

Inflammatory Bowel Disease (IBD)

Definition

- Crohn's disease (CD), ulcerative colitis (UC), indeterminate colitis, microscopic and collagenous colitis

Pathophysiology

- poorly understood
- sustained response of the immune system, perhaps to enteric flora in a genetically predisposed individual
- current hypothesis: lack of appropriate down-regulation of immune responsiveness

Genetics

- increased risk of both ulcerative colitis and Crohn's disease in relatives of patients with either disease, especially siblings, early onset disease
 - familial risk greater if proband has Crohn's than ulcerative colitis

- likely polygenomic pattern: 9 gene loci described to be associated
- CARD15 gene mutation associated with Crohn's (relative risk in heterozygote is 3, in homozygote is 40), especially Ashkenazi Jews, early onset disease, ileal involvement, fistulizing and stenotic disease (NOD2)
 - CARD15 gene product modulates NFκB, which is required for the innate immune response to microbial pathogens, best expressed in monocytes-macrophages

Clinical Features

Table 12. Clinical Differentiation of Ulcerative Colitis from Crohn's Colitis Disease

	Crohn's Disease	Ulcerative Colitis
Location	Any part of GI tract <ul style="list-style-type: none"> • Small bowel + colon: 50% • Small bowel only: 30% • Colon only: 20% 	Isolated to large bowel Always involves rectum, may progress proximally
Rectal Bleeding	Uncommon	Very common (90%)
Diarrhea	Less prevalent	Frequent small stools
Abdominal Pain	Post-prandial/colicky	Pre-defecatory urgency
Fever	Common	Uncommon
Palpable Mass	Frequent (25%), RLQ	Rare (if present, cecum full of stool)
Recurrent After Surgery	Common	None post-colectomy
Endoscopic Features	Discrete aphthous ulcers, patchy lesions, pseudopolyps	Continuous diffuse inflammation, erythema, friability, loss of normal vascular pattern, pseudopolyps
Histologic Features	Transmural distribution with skip lesions Focal inflammation ± noncaseating granulomas, deep fissuring + aphthous ulcerations, strictures Glands intact	Mucosal distribution, continuous disease (no skip lesions) Granulomas absent Gland destruction, crypt abscess
Radiologic Features	Cobblestone mucosa Frequent strictures and fistulae XR: Bowel wall thickening "string sign"	Lack of haustra Strictures rare and suggests complicating cancer
Complications	Strictures, fistulae, perianal disease	Toxic megacolon
Colon Cancer Risk	More than general population	More than general population

Crohn's Disease

Definition

- chronic inflammatory disorder potentially affecting the entire gut "from gum to bum"

Epidemiology

- incidence 1-6/100,000; prevalence 10-100/100,000
- bimodal: onset before 30 years, second smaller peak age 60
- incidence of Crohn's increasing (relative to UC) especially in young females
- more common in Caucasians, Ashkenazi Jews
 - risk in Asians increases with move to Western countries
- M=F; smoking incidence in Crohn's patients is higher than general population

Clinical Features

- natural history unpredictable
- most often presents as recurrent episodes of abdominal cramps, diarrhea and weight loss
- most common location: ileum + ascending colon
- ileitis may present with post-prandial pain, vomiting, RLQ mass; mimics acute appendicitis
- fistulae, fissures, abscesses are common
- extra-intestinal manifestations (see Table 13) are more common with colonic involvement
- linear ulcers leading to mucosal islands and "cobblestone" appearance
- deep fissures with risk of perforation into contiguous viscera (leads to fistulae and abscesses)
- enteric fistulae may communicate with skin, bladder, vagina and other parts of bowel
- granulomas are found in 50% of surgical specimens, 15% of mucosal biopsies

Investigations

- colonoscopy with biopsy to visualize (less often gastroscopy)
- CT enterography to visualize small bowel
- CRP elevated in most new cases, useful to monitor treatment response
- bacterial cultures, O&P, *C. difficile* toxin to exclude other causes of inflammatory diarrhea

Management (see Figure 7)

- smoking cessation
- medical management (most uncomplicated cases can be managed medically)
- diet
 - fluids only diet at start of acute exacerbation
 - enteral diets may aid in remission
 - apart from enteral diet, no evidence for any diet changing the natural history of Crohn's disease, but may affect symptoms
 - those with extensive small bowel involvement or extensive resection require electrolyte, mineral and vitamin supplements (vit D, Ca, Mg, zinc, Fe, B₁₂)
- 5-ASA
 - efficacy controversial: most evidence for mild colonic disease
 - sulfasalazine (Salazopyrin®): 5-ASA bound to sulfapyridine
 - ♦ hydrolysis by intestinal bacteria releases 5-ASA (active component)
 - ♦ dose-dependent efficacy
 - mesalamine (Pentasa®): coated 5-ASA releases 5-ASA in the ileum and colon
- antibiotics
 - e.g. metronidazole (20 mg/kg/d, bid or tid dosing)
 - best described for perianal Crohn's, although characteristically relapse when discontinued
 - side effects are common and reversible for metronidazole
 - ♦ 50% have peripheral neuropathy after 6 months of treatment, may not be reversible
 - ciprofloxacin also useful
- corticosteroids
 - prednisone: starting dose usually 40 mg OD for acute exacerbations; intravenous methylprednisolone if severe, then tapered
 - no proven role for steroids in maintaining remissions; masks intra-abdominal sepsis
 - complications of steroid therapy are dose and duration dependent
 - ♦ note: budesonide has fewer side effects than prednisone; start at 9 mg daily
- immunosuppressives
 - 6-mercaptopurine (6-MP), azathioprine (Imuran®); methotrexate used less often
 - more often used to maintain remission than to treat active inflammation
 - most commonly used as steroid-sparing agents
 - ♦ i.e. to lower risk of relapse as corticosteroids are withdrawn
 - may require >3 months to have beneficial effect; usually continued for several years
 - may help to heal fistulae, decrease disease activity
 - side effects: vomiting, pancreatitis, bone marrow suppression, increased risk of malignancy
- antidiarrheal agents
 - loperamide (Imodium®) > diphenoxylate (Lomotil®) > codeine (cheap but addictive)
 - all work by decreasing small bowel motility
 - caution if colitis is severe (risk of precipitating toxic megacolon)
 - avoid if significant mucosal inflammation
- cholestyramine
 - a bile-salt binding resin
 - for watery diarrhea with <100 cm of terminal ileum diseased or resected
 - however, non-specific anti-diarrheals are more convenient and often more potent
- biologicals
 - infliximab IV (Remicade®) or adalimumab SC (Humira®): antibody to TNF- α
 - proven effective for treatment of fistulae and patients with medically refractory CD
 - first-line immunosuppressive therapy with infliximab + immunosuppressives more effective than using either alone
 - anti-TNF therapy often effective within days, generally well-tolerated
 - side effect: reported cases of reactivated TB, PCP, other infections
- surgical treatment (see **General Surgery**, GS29)
 - surgery generally reserved for complications such as fistulae, obstruction, abscess, perforation, bleeding and for medically refractory disease
 - ♦ if <50% or <200 cm of functional small intestine, risk of short bowel syndrome
 - at least 50% clinical recurrence within 5 years; 85% within 15 years; endoscopic recurrence rate even higher
 - 40% likelihood of second bowel resection, 30% likelihood of third bowel resection
 - complications of ileal resection:
 - ♦ <100 cm resected \rightarrow watery diarrhea (impaired bile salt absorption)
 - treatment: cholestyramine or anti-diarrheals e.g. loperamide
 - ♦ >100 cm resected \rightarrow steatorrhea (reduced mucosal surface area, bile salt deficiency)
 - treatment: fat restriction, medium chain triglycerides prn

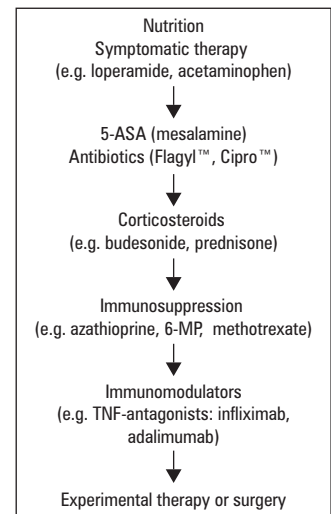

Figure 7. Traditional Graded Approach to Induction Therapy in Crohn's

Medical Management of Crohn's

	Induced Remission	Maintenance
5-ASA	+	?
Steroids	+	
Immunosuppressive	+	+
Antibiotics	+	
MTX	+	+
Infliximab	+	+

Characteristically more than 1 year between onset of symptoms and diagnosis of Crohn's disease.

Biological Therapies for Inflammatory Bowel Diseases

Gastroenterol 2009; 136:1182-97

Although the etiology of inflammatory bowel diseases (IBD) is unknown, biological therapies (BT) that target key molecules in innate and adaptive immune pathways have been designed.

Anti-TNF: (infliximab, adalimumab, certolizumab) It improves treatment of CD, less for UC. It increases mucosal healing, decreases need for hospitalizations and surgeries, and can induce steroid-free remission. At least 10% of patients annually develop intolerance and/or a loss of response.

Selective Anti-Adhesion Molecules: (natalizumab) It increases response and remission rates, circulating leukocytes and steroid-sparing capacity in CD. Progressive multifocal leukoencephalopathy is a rare adverse event.

Promising New BT: Anti-Interleukin-12/ Interleukin-23 p40 target factors more often associated with CD, while anti-IFN-antibodies may treat CD and UC.

BT Without Established Efficacy: Recombinant human cytokines, blockade of T-cell activation (dacizumab and basiliximab) and stimulators of the innate immune system.

Conclusion: Anti-TNF is an effective treatment for IBD. There is a need to develop an effective treatment for patients who do not respond to a first biological drug. BT's have a safety risk, so their place in treatment algorithms must be defined carefully.

Prognosis

- highly variable course
- 10% chronic, relapsing
- 10% disabled by the disease eventually
- increased mortality, especially with more proximal disease, greatest in the first 4-5 years
- intestinal obstruction due to edema, fibrosis
- fistula formation
- intestinal perforation characteristically contained (free perforation uncommon)
- malignancy: increased risk especially with colonic involvement, but less risk compared to ulcerative colitis
- surveillance colonoscopy same as ulcerative colitis (see below) if more than 1/3 of colon involved

**Ulcerative Colitis (UC)****Definition**

- inflammatory disease affecting colonic mucosa anywhere from rectum to cecum, but rectum always involved

Epidemiology

- incidence 2-10/100,000; prevalence 35-100/100,000 (more common than Crohn's)
- 2/3 onset by age 30 (with second peak after 50); M=F
- small hereditary contribution (15% of cases have 1st degree relative with disease)
- risk is less in smokers
- inflammation limited to rectum or left colon more common than pancolitis

Pathology

- disease can involve any portion of lower bowel from rectum only (proctitis) to entire colon (pancolitis)
- rectum always involved
- inflammation diffuse, continuous and confined to mucosa

Clinical Features

- chronic disease most frequently characterized by diarrhea and rectal bleeding
 - can also have abdominal cramps/pain, especially with defecation
- severity of colonic inflammation correlates with symptoms (stool volume, amount of blood in stool)
- tenesmus, urgency, incontinence
- systemic symptoms: fever, anorexia, weight loss, fatigue in severe cases
- extra-intestinal manifestations (see Table 13)
- characteristic exacerbations and remissions; 5% of cases are fulminant

In UC's initial presentation, non-bloody diarrhea is frequently seen; eventually progresses to bloody diarrhea.

Investigations

- sigmoidoscopy with mucosal biopsy (to exclude self-limited colitis) without bowel prep often sufficient for diagnosis
- colonoscopy helpful to determine extent of disease; contraindicated in severe exacerbation
- CT colonography (formerly barium enema) if colonoscopy cannot be done; contraindicated in severe disease
- stool culture, microscopy, *C. difficile* toxin assay necessary to exclude infection
- no single confirmatory test

Management

- mainstays of treatment: 5-ASA derivatives and corticosteroids, with azathioprine used in steroid-dependent or resistant cases
- diet of little value in decreasing inflammation but may alleviate symptoms
- antidiarrheal medications generally not indicated in UC
- 5-ASA
 - topical (suppository or enema): very effective for distal disease (distal to splenic flexure), preferable to corticosteroids
 - oral: effective for mild to moderate, but not severe colitis
 - e.g. sulfasalazine 3-4 g/d, mesalamine 4 g/d
 - useful only for mild to moderate disease, not for severe disease
 - more commonly used in maintaining remission (decreases yearly relapse rate from 60% to 15%)
 - may decrease rate of colorectal cancer

- corticosteroids
 - to remit acute disease, especially if severe or first attack; may need maximum dose IV steroids initially (e.g. methylprednisolone 30 mg IV q12h)
 - limited role as maintenance therapy
 - use suppositories for proctitis, enemas for proctosigmoiditis
 - topical steroids (e.g. hydrocortisone foam, budesonide enemas) for inflammation distal to splenic flexure
- immunosuppressants (steroid-sparing)
 - if severe UC is refractory to steroid therapy, consider adding IV cyclosporine or IV infliximab – rapidly effective but helpful only in a minority of patients
 - azathioprine: too slow to rapidly resolve acute relapse
 - ◆ most commonly used to induce and maintain remission as corticosteroids withdrawn
 - infliximab entering routine clinical use
- surgical treatment
 - early in severe especially fulminant cases and toxic megacolon – consider operation if no response after 5 days of medical therapy
 - aim for cure with colectomy
 - indications: failure of adequate medical therapy, toxic megacolon, bleeding, pre-cancerous changes picked up by screening endoscopic biopsies (dysplasia)

Medical Management of Ulcerative Colitis

	Induced Remission	Maintenance
5-ASA	+	+
Steroids	+	
Immunosuppressive	+/-	+

Complications

- similar to CD, except:
 - more liver problems (especially primary sclerosing cholangitis [PSC] in men)
 - greater risk of colorectal cancer
 - ◆ risk increases with duration and extent of disease (5% at 10 years, 15% at 20 years for pancolitis; overall RR is 8%)
 - ◆ risk also increases with presence of sclerosing cholangitis, family history of colorectal cancer
 - ◆ thus, regular colonoscopy and biopsy in pancolitis of ≥ 8 years is indicated
 - toxic megacolon (transverse colon diameter >6 cm on abdominal x-ray) with immediate danger of perforation (see General Surgery, GS29)

Prognosis

- chronic relapsing pattern in most patients
- 10-15% chronic continuous pattern
- >1 attack in almost all patients
- more colonic involvement in the 1st year correlates with increased severity of attacks and increased colectomy rate
 - colectomy rate = 1% for all patients after the 1st year; 20-25% eventually undergo colectomy
- normal life expectancy
- if proctitis only, usually benign course

When Considering Complications of IBD, Think: ULCERATIVE COLITIS

Urinary Calculi
 Liver problems
 Cholelithiasis
 Epithelial problems
 Retardation of growth/sexual maturation
 Arthralgias
 Thrombophlebitis
 Iatrogenic complications
 Vitamin deficiencies
 Eyes
 Colorectal cancer
 Obstruction
 Leakage (perforation)
 Iron deficiency
 Toxic megacolon
 Inanition (wasting)
 Strictures, fistulae

Table 13. Extraintestinal Manifestations of IBD

System	Crohn's Disease	Ulcerative Colitis
Dermatologic		
Erythema Nodosum	15%	10%
Pyoderma Gangrenosum	10%	Less common
Perianal skin tags	75-80%	Rare
Oral mucosal lesions	Common	Rare
Psoriasis	Statistically associated in 5-10% of those with IBD but not an EIM	
Rheumatologic		
Peripheral arthritis	15-20% of those with IBD (CD>UC)	
Ankylosing Spondylitis	10% of those with IBD (CD>UC)	
Sacroiliitis	Occurs equally in CD and UC	
Ocular (~10% of IBD)		
Uveitis (vision threatening)		
Episcleritis (benign)	3-4% of IBD patients (CD>UC)	
Hepatobiliary		
Cholelithiasis	15-35% of patients with ileal Crohn's	
Primary sclerosing cholangitis (PSC)	1-5% of IBD cases involving colon	
Fatty liver		
Urologic		
Calculi	Most common in CD, especially following ileal resection	
Ureteral obstruction		
Fistulas	Characteristic of Crohn's	
Others		
Thromboembolism		
Vasculitis		
Osteoporosis		
Vitamin deficiencies (B ₁₂ , Vit ADEK)		
Cardiopulmonary disorders		
Pancreatitis (rare)		

Irritable Bowel Syndrome (IBS)

Definition

- a form of functional, but specific bowel disease, not just a label for all GI symptoms that are unexplained after investigation

Epidemiology

- 20% of North Americans
- onset of symptoms usually in young adulthood
- F>M

Pathophysiology

- normal perception of abnormal gut motility vs. abnormal perception of normal gut motility
- abnormal motility: multiple abnormalities described, may be causative
- psychological: stress may increase IBS symptoms but does not cause IBS

Diagnosis

Table 14. Rome III Criteria for Diagnosing Irritable Bowel Syndrome

IBS Rome III Criteria	
<ul style="list-style-type: none"> • ≥12 weeks in the past 12 months of abdominal discomfort or pain that has 2 out of 3 features: <ul style="list-style-type: none"> • Relieved with defecation • Associated with a change in frequency of stool • Associated with a change in consistency of stool • The following are supportive, but not essential to the diagnosis: <ul style="list-style-type: none"> • Abnormal stool frequency (>3/day or <3/week) • Abnormal stool form (lumpy/hard/loose/watery) >1/4 of defecations • Abnormal stool passage (straining, urgency, feeling of incomplete evacuation) >1/4 of defecations • Passage of mucus >1/4 of defecations 	
Diagnosis of IBS less likely in presence of "Alarm" Features	
<ul style="list-style-type: none"> • Weight loss • Fever • Nocturnal defecation 	<ul style="list-style-type: none"> • Anemia • Blood or pus in stool • Abnormal gross findings on flexible sigmoidoscopy
Normal Physical Exam	

Investigations

- not required if history consistent with Rome III criteria or younger patient, no alarm symptoms
- aim is to rule out:
 - enteric infections e.g. *Giardia*
 - lactose intolerance/other disaccharidase deficiency
 - Crohn's disease
 - celiac sprue
 - drug-induced diarrhea
 - diet-induced (excess tea, coffee, colas)
- CBC, TSH, albumin, CRP, tTG serology with protein electrophoresis
- stool for C&S, O&P, fat excretion if diarrhea present
- consider sigmoidoscopy

Management

- reassurance, explanation, support, aim for realistic goals
- relaxation therapy, biofeedback, hypnosis, stress reduction
- bran or psyllium for constipation, loperamide for diarrhea
- no therapeutic agent consistently effective
 - tricyclic antidepressants may provide visceral analgesia
- symptom-guided treatment
 - pain predominant
 - ♦ antispasmodic medication before meals (e.g. hyosine, pinaverium, trimebutine)
 - ♦ increased fibre diet
 - ♦ tricyclic antidepressants (TCA), selective serotonin reuptake inhibitors (SSRI)
 - ♦ visceral antinociceptive agent
 - diarrhea predominant
 - ♦ increase fibre in diet to increase stool consistency
 - ♦ loperamide 2-4 mg tid/qid
 - ♦ diphenoxylate (Lomotil®)
 - ♦ cholestyramine 4 g qid
 - constipation predominant
 - ♦ exercise and adequate fluid intake
 - ♦ increase fibre in diet
 - ♦ osmotic or other laxatives

Prognosis

- 80% improve over time
- most have intermittent episodes
- normal life expectancy

Constipation

**Definition**

- passage of infrequent or hard stools with straining (stool water <50 mL/day); bowel frequency <3 times/week

Epidemiology

- increasing prevalence with age, F>M
- rare in Africa and India where stool weight is 3-4x greater than in Western countries

Etiology

- most common: colon dysmotility
- organic causes
 - medication side effects (narcotics, antidepressants), most common
 - intestinal obstruction, left sided colon cancer (consider in older patients), fecal impaction
 - metabolic
 - ♦ diabetes mellitus (DM)
 - ♦ hypothyroidism
 - ♦ hypercalcemia, hypokalemia, uremia
 - neurological
 - ♦ intestinal pseudo-obstruction
 - ♦ Parkinson's disease
 - ♦ multiple sclerosis (MS)
 - collagen vascular disease (e.g. scleroderma)
 - painful anal conditions (e.g. fissures)

**Causes of Constipation**

DOPED
 Drugs
 Obstruction
 Pain
 Endocrine dysfunction
 Depression

Clinical Presentation

- overlaps with irritable bowel syndrome
- abdominal pain relieved by defecation, hard stools, straining and pain with defecation, flatulence, overflow diarrhea, sense of incomplete evacuation, abdominal distention, <3 BM/week

Investigations

- consider colon visualization (colonoscopy, CT colonography), although chronic constipation by itself is rarely due to colonic mucosal disease
- classification based on colon transit time, can be quantitated by swallowing radio-opaque markers to measure colonic transit time (normal: 70 hours)
 - (1) normal = misperception of normal defecation, probably form of irritable bowel syndrome
 - (2) prolonged throughout = "colonic inertia" (infrequent bowel movements with gas/bloating, tends to occur in youth)
 - (3) outlet obstruction = inability to coordinate pelvic floor muscles to empty rectum, straining, stool in rectum on digital exam, tends to occur in old age
- combination of (2) and (3) common

Treatment (in order of increasing potency)

- dietary fibre
 - useful if mild or moderate constipation, but not if severe
 - aim for 30 g daily, increase dose slowly
- surface-acting (soften and lubricate)
 - docusate salts, mineral oils
- osmotic agents (effective in 2-3 days)
 - lactulose, sorbitol, magnesium citrate, magnesium sulfate, magnesium hydroxide, lactitol, Milk of Magnesia, polyethylene glycol 3350
- cathartics (effective in 24 hrs)
 - castor oil, senna (avoid prolonged use to prevent melanosis coli)
- enemas and suppositories (e.g. saline enema, phosphate enema, glycerin suppository)

Upper Gastrointestinal Bleeding

Definition

- bleeding proximal to the ligament of Treitz (75% of GI bleeds)
 - ligament of Treitz: suspensory ligament where fourth portion of the duodenum transitions to jejunum

Clinical Features

- in order of decreasing severity of the bleed: hematochezia > hematemesis > melena > occult blood in stool

Etiology

- above the GE junction
 - epistaxis
 - esophageal varices (10-30%)
 - esophagitis
 - esophageal cancer
 - Mallory-Weiss tear (10%)
- stomach
 - gastric ulcer (20%) (see *Peptic Ulcer Disease*, G11)
 - gastritis (e.g. from alcohol or post-surgery) (20%)
 - gastric cancer
- duodenum
 - ulcer in bulb (25%)
 - aortoenteric fistula: usually only if previous aortic graft (see sidebar)
- coagulopathy (drugs, renal disease, liver disease)
- vascular malformation (Dieulafoy's lesion, AVM)

Management (initial)

- stabilize patient (2 large bore IVs, IV fluids, monitor)
- send blood for CBC, cross and type, platelets, PT, PTT, electrolytes, BUN, Cr, LFTs
- keep NPO
- consider NG tube to determine upper vs. lower GI bleeding in some cases
- endoscopy (OGD): establish bleeding site + treat lesion
 - if bleeding peptic ulcer: most commonly used method of controlling bleeding is injection of epinephrine around bleeding point + thermal hemostasis (bipolar electrocoagulation or heater probe) – less often thermal used alone, but injection alone not recommended
 - endoclips

Aortoenteric Fistula is a rare and lethal cause of GI bleed, most common in patients with a history of aortic graft surgery. Therefore, perform emergency endoscopy if suspected, emergency surgery if diagnosed.

Note: The window of opportunity is narrow. Suspect if history of aortic graft, abdominal pain associated with bleeding.

Always ask about NSAID/aspirin or anticoagulant therapy in GI bleed.

Forrest Classification of Peptic Ulcers

Forrest Class	Type of lesion	Risk of Rebleed (%)
I	Arterial Bleeding (oozing/spurting)	55-100
Ila	Visible Vessel	43
Ilb	Sentinel Clot	22
Ilc	Hematin Covered Flat Spot	10
III	No Stigmata of Hemorrhage	5

Reference: Forrest JA, Finlayson ND, Shearman DJ. Endoscopy in Gastrointestinal Bleeding. *Lancet* 1974; (17):394-397.

- IV PPI: decrease risk of rebleed if endoscopic predictors of rebleeding seen (see below)
 - given to stabilize clot, not to accelerate ulcer healing
 - if given before endoscopy, decreases need for endoscopic therapeutic intervention
- for variceal bleeds, octreotide 50 µg loading dose followed by constant drip of 50 µg/hr
- consider IV erythromycin (or metoclopramide) prior to gastroscopy to remove clots from stomach

Prognosis

- 80% stop spontaneously
- peptic ulcer bleeding: low mortality (2%) unless rebleeding occurs (25% of patients, 10% mortality)
- endoscopic predictors of rebleeding: spurt or ooze, visible vessel, fibrin clot
- can send home if clinically stable, bleed is minor, no comorbidities, endoscopy shows clean ulcer with no predictors of rebleeding
- H₂-antagonists have little impact on rebleeding rates and need for surgery
- esophageal varices have a high rebleeding rate (55%) and mortality (29%)

Bleeding Peptic Ulcer

Clinical Features

- see *Peptic Ulcer Disease*, G11

Management

- OGD to explore upper GI tract (see Figure 8)
- establish risk of rebleeding/continuous bleed
 - risk factors: increased age (>60), bleeding diathesis, previous history of PUD, comorbid disease, hemodynamically unstable
 - ♦ if high risk, consider ICU admission

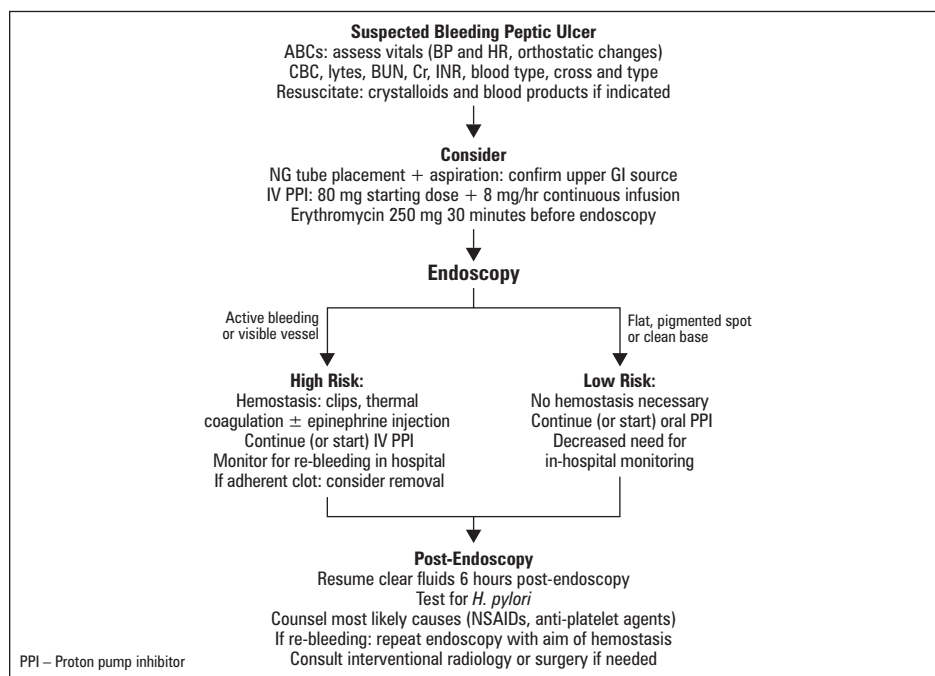

Figure 8. Approach to Management of Suspected Bleeding Peptic Ulcer

Adapted from Gralnek I, Barkun A, Bardou M. Management of acute bleeding from a peptic ulcer. *NEJM* 2008; 359:928-937.

Esophageal Varices

Etiology

- almost always due to portal hypertension
- often accompanied by varices in stomach

Clinical Features

- characteristically massive upper GI bleeding

Investigations

- endoscopy

Bleeding Peptic Ulcers: Risk Factors for Mortality

Co-existent illness
Hemodynamic instability
Age >60 years
Transfusion required

Proton Pump Inhibitor Treatment for Acute Peptic Ulcer Bleeding

Cochrane Database Syst Rev 2006; (1):CD002094

Purpose: To review the efficacy of proton pump inhibitors (PPIs) in acute bleeding from peptic ulcers (PU).

Study Selection: RCTs of PPI treatment compared with placebo or H₂-receptor antagonist (H₂RA) in acute bleeding from PU.

Results: 24 trials (n=4373) were reviewed. There was no significant difference in all-cause mortality rates between PPI and control treatment. PPIs significantly reduced rebleeding compared to control (10.6% PPI versus 17.3% control; OR 0.49), as well as the need for surgery (6.1% PPI versus 9.3% control; OR 0.61).

Conclusion: PPIs should be administered to patients with endoscopically-documented PU bleeding from "high risk" ulcers (ie at high risk of rebleeding: active bleeding, visible vessel, clot) at endoscopy despite the lack of evidence of an overall effect mortality.

Intragastric pH with Oral vs. Intravenous Bolus plus Infusion Proton-pump Inhibitor Therapy in Patients with Bleeding Ulcers

Gastroenterol 2008; 134:1836-41

Study: Randomized control trial.

Participants: Patients presenting with overt bleeding from an ulcer.

Intervention: Patients received either IV lansoprazole (90 mg bolus followed by 9 mg/h infusion; n=32) or oral lansoprazole (120 mg bolus followed by 30 mg every 3 hours; n=34).

Primary Outcome: 24 hour pH

Results: Intragastric pH was > 6 for > 60% of the study period in 22 (68.8%) patients receiving IV and 22 (64.7%) patients receiving oral PPI. At 1 hour, mean pHs for IV and oral were 5.3 and 3.3, respectively (difference 2.0; P=0.001). After 1.5 hours, there were no differences in mean pH between the groups. Mean pH rose above 6 after 2-3 hours of IV PPI and 3-4 hours of oral PPI.

Conclusion: Frequent oral PPI may be able to replace the currently recommended IV bolus plus infusion PPI therapy in patients with bleeding ulcers. However, IV PPI has a more rapid increase in pH, reaching mean pH of 6 approximately 1 hour sooner than oral PPI.

If varices isolated to stomach, think of splenic vein thrombosis.

Management

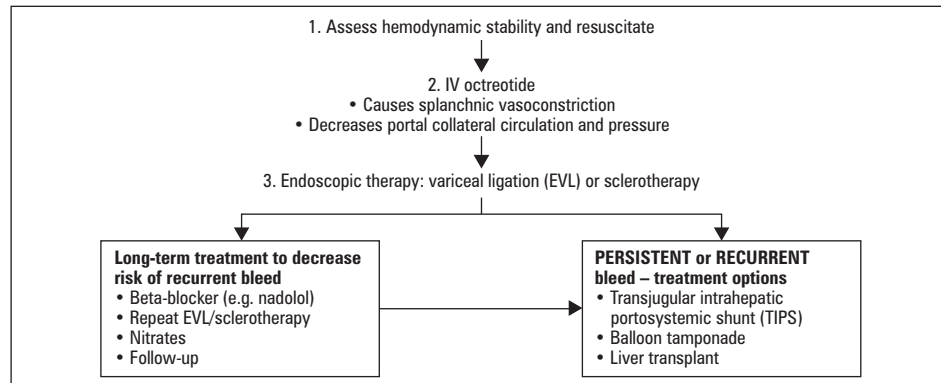

Figure 9. Management of Bleeding Esophageal Varices

Mallory-Weiss Tear

Definition

- longitudinal laceration in gastric mucosa on lesser curvature near GE junction (20% straddle junction, 5% in distal esophagus)

Etiology

- due to rapid increases in gastric pressure (e.g. retching/vomiting against a closed glottis)
- most patients abuse alcohol
- hiatus hernia usually present

Clinical Features

- hematemesis ± melena, classically following an episode of retching
- can lead to fatal hematemesis

Management

- 90% stop spontaneously
- if persistent: endoscopy with injection ± clips or surgical repair

Lower Gastrointestinal Bleeding

Definition

- bleed distal to ligament of Treitz

Etiology

- rule out upper GI source
- diverticular (60% from right colon)
- vascular
 - angiodysplasia
 - anorectal (hemorrhoids, fissures)
- neoplasm
 - cancer
 - polyps
- inflammation
 - colitis (ulcerative, infectious, radiation, ischemic)
- post-polypectomy

Clinical Features

- hematochezia (see Figure 10)
- anemia
- occult blood in stool
- rarely melena

When suspecting lower GI bleed, first and foremost exclude upper GI bleeding before localizing the site of the lower GI bleed.

Lower GI Bleed

CHAND

Colitis [radiation, infectious, ischemic, IBD (UC > CD)]
Hemorrhoids/fissure
Angiodysplasia
Neoplastic
Diverticular disease

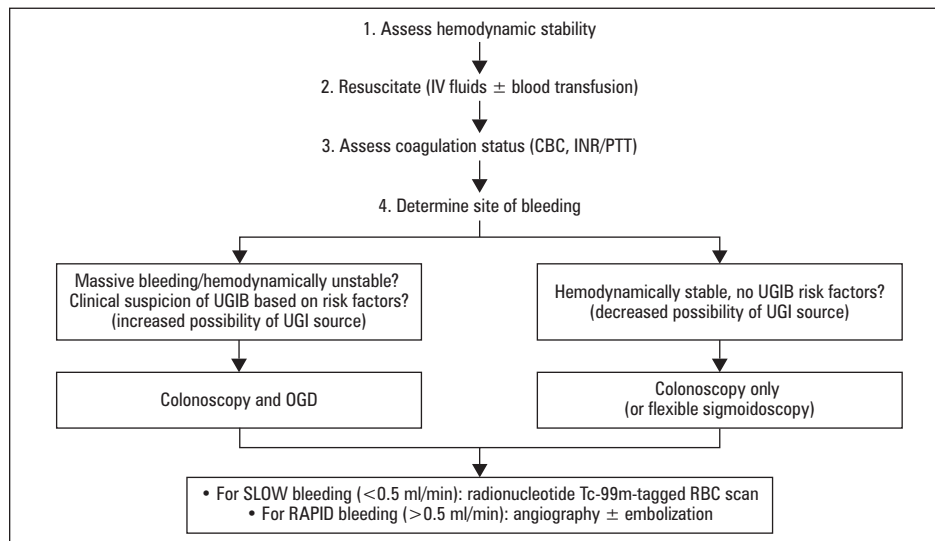

Figure 10. Approach to Hematochezia

Colorectal Cancer

- see General Surgery, GS32

Etiology/Epidemiology

- environmental influences: high dietary fat, low dietary fibre
- genetic influences:
 - all colorectal cancers considered to have genetic component, to varying degrees
 - familial syndromes (see *Familial Colon Cancer Syndromes*, G30)
 - multiple “step-wise” somatic mutations, contributed by environment, have been implicated
 - genetic changes implicated:
 - ♦ activation of proto-oncogenes (K-ras)
 - ♦ loss of tumour-suppressor gene activity (APC, DCC)
 - ♦ abnormalities in DNA repair genes (hMSH2, hMLH1), especially HNPCC syndromes

Pathophysiology

- normal colon → hyperproliferative epithelium → adenoma → carcinoma

Risk Factors

- 75% of new cases are in people with no known risk factors
- age
 - 90% of cancers are in people >50 years old
 - at age 50, the risk of developing colorectal cancer by age 80 is 5%
- adenomatous polyps
- family history
 - sporadic cancer
 - ♦ risk increases 1.8x for those with one affected relative, 2-6x with two affected relatives
 - ♦ risk is greater if relative has cancer diagnosed <45 years old
 - familial adenomatous polyposis and Gardner's syndrome
 - hereditary nonpolyposis colorectal cancer (Lynch syndrome or HNPCC)
- IBD
 - UC – after 10 years, cancer risk increased approximately by 1% for each additional year
 - Crohn's disease – unclear, likely similar to UC if more than 1/3 of colon inflamed

Prevention

- increase fibre in diet, decrease animal fat and red meat, decrease smoking and EtOH, increase exercise and decrease BMI
- aspirin
- secondary prevention with screening (see sidebar)

Prognosis

- stage 1 (limited to wall of bowel): 95%
- stage 2 (through wall of bowel): 80%
- stage 3 (into lymph nodes): 50%

Treatment (see General Surgery)

Some colon cancers may bleed intermittently or not at all. No bleeding does not rule out cancer.

Melena more often seen with right-sided tumours.
Hematochezia more often seen with left-sided tumours.

Colorectal Cancer Screening
Canadian Association of Gastroenterology, *Can J Gastroenterol* 2004; 18(2)

People at average risk:

- >50, no family history should undergo one of:
 - FOBT q 2 years
 - Flexible sigmoidoscopy q 5 years
 - Combined FOBT and flex sig q 5 years
 - Double contrast barium enema q 5 years (more recently CT colonography replaces barium enema)
 - Colonoscopy q 10 years

People at above-average risk:

- HNPCC – Genetic testing + colonoscopy q 2 years beginning at age 20
- FAP – Genetic testing + sigmoidoscopy annually beginning at age 10-12
- Fam Hx of cancer (One or more first degree relatives with CRC i.e. parent, sibling or child) or polyps but does not fit criteria for HNPCC/FAP – colonoscopy q 5 years beginning at age 40 or 10 years earlier than the youngest diagnosed polyp/cancer case in the family.

Colorectal Polyps

Definition

- small mucosal outgrowth into the lumen of the colon or rectum
- sessile (flat) or pedunculated (on a stalk)

Epidemiology

- 30% of population (with no family history or polyps or colorectal cancer) have polyps by age 50, 40% by age 60, 50% by age 70

Clinical Features

- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, but may have rectal bleeding, change in bowel habits (less common)
- usually detected during routine endoscopy or family screening

Pathology

- hyperplastic: most common, no malignant potential, except sessile serrated type
- inflammatory (or pseudopolyps): associated with CD and UC, no malignant potential
- hamartomas: juvenile polyps, Peutz-Jegher syndrome (characteristically small bowel)
 - malignant risk due to associated adenomas (large bowel)
 - low malignant potential → most spontaneously regress or auto-amputate
- adenomas: premalignant, carcinoma in situ may occur
 - some may contain invasive carcinoma ("malignant polyp", 2.6-9.4%): invasion into muscularis
 - tubular, tubulovillous, villous (see Table 15)

Table 15. Characteristics of Tubular vs. Villous Polyps

	Tubular	Villous
Incidence	Common (60% to 80%)	Less common (10%)
Size	Small (<2 cm)	Large (usually >1 cm)
Attachment	Pedunculated/sessile	Sessile
Malignant Potential	Lower	Higher
Distribution	Even	Left-sided predominance

Investigations

- flexible sigmoidoscopy can reach 60% of polyps in men and 35% of polyps in women; if polyps detected, proceed to colonoscopy for examination of entire bowel and biopsy
- colonoscopy remains the gold standard

Treatment

- endoscopic polypectomy; surgical segmental resection if unsuccessful/impossible
- follow-up for adenomas: repeat colonoscopy in 5 years; in 3 years if polyp diameter >1 cm, ≥3 adenomas, sessile, high grade dysplasia, villous

Familial Colon Cancer Syndromes

FAMILIAL ADENOMATOUS POLYPOSIS (FAP)

Pathogenesis

- autosomal dominant (AD) inheritance, mutation in APC gene on 5q
- plays a major role in sporadic cancer

Clinical Features

- hundreds to thousands of colonic adenomas by an average age of 40
- extracolonic manifestations
 - carcinoma of duodenum, small bowel, stomach, bile duct, pancreas, thyroid, adrenal
 - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients
- virtually 100% lifetime risk of colon cancer (because of number of polyps)
- variants:
 - Gardner's syndrome: FAP + extraintestinal lesions (chiefly bone, desmoid tumours)
 - Turcot's syndrome: FAP + CNS tumours

Investigations

- genetic testing (80-95% sensitive, 99-100% specific)
 - see sidebar for criteria for genetic screening referral
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then regular screening

Note that rectal cancers have a higher recurrence rate and lower 5-year survival rate than colon cancers. Therefore, do a rectal exam.

Referral Criteria for Genetic Screening for APC

- To confirm the diagnosis of FAP (in patients with ≥100 colorectal adenomas)
- To provide pre-symptomatic testing for individuals at risk for FAP (1st degree relatives who are ≥10 years old)
- To confirm the diagnosis of attenuated FAP (in patients with ≥20 colorectal adenomas)

Treatment

- surgery indicated by age 17-20
- total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis (needs intensive endoscopic surveillance of rectal stump) or pelvic pouch with ileo-anal anastomosis
- chemotherapy for intra-abdominal desmoids

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER (HNPCC)**Pathogenesis**

- AD inheritance, mutation in a DNA mismatch repair gene resulting in genomic instability and subsequent mutations
- plays a minor role in sporadic cancer

Clinical Features

- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 years, lifetime risk 70-80% (greater for men)
- Lynch syndrome I: hereditary site-specific colon cancer
- Lynch syndrome II: cancer family syndrome – high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis

- diagnosis is clinical – based on Amsterdam Criteria (see sidebar)

Investigations

- genetic testing (80% sensitive) – colonoscopy mandatory even if negative
 - refer for genetic screening individuals who fulfill either the Amsterdam criteria (see sidebar) or revised Bethesda criteria (see sidebar)
- colonoscopy (starting age 20) every 1-2 years
- surveillance for extracolonic lesions (controversial, no guidelines available)

Treatment

- subtotal colectomy and ileosigmoid or ileorectal anastomosis with yearly proctoscopy or sigmoidoscopy

**"Amsterdam" Criteria for HNPCC Diagnosis**

- 3 relatives with colorectal cancer, where one is 1st degree relative of other two
- 2 generations of colorectal cancer
- 1 colorectal cancer before age 50
- FAP is excluded

**Revised Bethesda Criteria – Refer for Genetic Screening for HNPCC**

- Individuals with cancer in families that meet the Amsterdam criteria
- Patients with two HNPCC-related cancers, including synchronous and metachronous colorectal cancer or associated extracolonic cancers (endometrial, ovarian, gastric, hepatobiliary, small bowel, or transitional cell carcinoma of the renal pelvis or ureter)
- Patients with colorectal cancer and a first degree relative with colorectal cancer and/or HNPCC-related extracolonic cancer and/or a colorectal adenoma with one of the cancers diagnosed before age 45 years, and the adenoma diagnosed before age 40 years
- Patients with right-sided colorectal cancer having an undifferentiated pattern (solid/ciriform) on histopathologic diagnosis before age 45 years
- Patients with signet-ring cell type colorectal cancer diagnosed before age 45
- Patients with adenomas diagnosed before age 40

Liver

Investigations of Hepatobiliary Disease

A. TEST OF LIVER FUNCTION**Prothrombin Time (PT or INR)**

- most sensitive marker of hepatic protein synthesis
- increased by:
 - impaired hepatic protein synthesis (>80%) (including all coagulation factors except VIII)
 - vitamin K deficiency; PT reliable marker of liver dysfunction only if vitamin K administration ruled out

Serum Albumin Level

- must exclude malnutrition, renal or GI losses and acute illness

Serum Bilirubin

- marker of hepatic excretion: transport from hepatocyte to bile
- canaliculus breakdown product of hemoglobin; metabolized in the reticuloendothelial system of liver, transported through biliary system, excreted via gut
- direct bilirubin = conjugated; indirect = unconjugated bilirubin
- liver dysfunction causes hyperbilirubinemia (elevated direct bilirubin) since conjugation preserved even in end stage liver failure

All clotting factors except factor VIII and von Willebrand Factor are exclusively synthesized in the liver.

**Serum transaminases >1000 due to**

- Viral hepatitis
- Drugs
- Autoimmune hepatitis
- Hepatic ischemia
- Rarely common bile duct stone

ALT > AST = most causes of hepatitis
 AST > ALT = alcoholic liver disease or other causes of hepatitis that have progressed to advanced cirrhosis
 Alcoholic hepatitis: history of recent alcohol, RUQ abdominal pain, AST/ALT > 2, AST usually < 300, low grade fever, mildly elevated WBC

DDx for Hepatomegaly

- Congestive (right heart failure, Budd-Chiari syndrome)
- Infiltrative
 - Malignant (primary, secondary, lymphoproliferative, leukemia)
 - Benign (fatty liver, cysts, hemochromatosis, extramedullary hematopoiesis, amyloid)
- Proliferative
 - Infectious (viral, tuberculosis, abscess, echinococcus)
 - Inflammatory (granulomas [sarcoid], histiocytosis X)

B. TESTS OF LIVER DAMAGE

- increased AST, ALT = hepatocellular damage
 - ALT more specific to liver; AST from multiple sources (especially muscle)
 - elevation of both highly suggestive of liver injury
 - most common cause of elevated ALT is fatty liver
 - if AST, ALT > 1000, think of acute viral infection, drug-induced liver injury, ischemia (acute congestion or hypotension), autoimmune hepatitis, common bile duct stone (rare)
- increase in ALP and GGT = cholestasis
 - if ALP is elevated alone, rule out bone disease by fractionating ALP
 - obstruction of large duct (common bile duct): extraluminal (pancreatic CA, lymphoma), wall inflammation/stricturing, intraluminal (stones, helminths)
 - ♦ obstruction of microscopic ducts (PBC, PSC)
 - ♦ bile acid transporter defects (drugs, intrahepatic cholestasis of pregnancy)
 - ♦ infiltration of the liver (liver metastases, lymphoma, granulomas, amyloid)

Hepatitis – Acute and Chronic

- see [Infectious Diseases](#), ID18

Etiology

- viral infection
- alcohol
- drugs
- immune-mediated
- toxins

Hepatitis A Virus (HAV)

- RNA virus
- fecal-oral transmission; incubation period 4-6 weeks
- diagnosed by elevated transaminases, positive anti-HAV IgM
- in children: characteristically asymptomatic
- in adults: fatigue, nausea, arthralgia, fever, jaundice
- can cause fulminant hepatic failure and subsequent death (<1-5%)
- can relapse but never becomes chronic

Risk of Developing Infection from a Hollow Needle Puncture

HBV	30%
HCV	3%
HIV	0.3%

Hepatitis B Virus (HBV)

Table 16. Hepatitis B Serology

	HBsAg	Anti-HBs	HBeAg	Anti-HBe	Anti-HBc	Liver Enzymes
Acute HBV	+	–	+	–	IgM	
Chronic HBV (high HBV DNA)	+	–	+	–	IgG	ALT, AST elevated
Chronic HBV (low HBV DNA)	+	–	–	+	IgG	ALT, AST normal
Resolved infection	–	+/-	–	+/-	IgG	
Immunization	–	+	–	–	–	

Causes of Elevated Serum Transaminases in Chronic Hepatitis B

- Ongoing immune mediated liver injury without immune control of HBV
- Reactivation from prior immune control due to lack of adequate immune control
- Seroconversion (HBeAg converting to anti-HBe; spontaneously or with Rx)
- Hepatitis D
- Liver insult (fatty liver, alcohol, drugs, hepatitis A)

Figure 11. Time Course of Acute Hepatitis B Infection

Epidemiology

- 4 phases of chronic hepatitis B: not all go through all 4 phases but all have positive HBsAg
 - immune tolerance:** extremely high HBV-DNA, HBeAg positive, but normal ALT/AST due to little immune control and minimal immune-mediated liver damage, characteristic of perinatal infection (or 'incubation period' in adult with newly acquired HBV)
 - immune clearance** (or immunoactive): falling HBV DNA levels but still high (>10,000 IU/mL), HBeAg positive, due to immune attack on the virus and immune-mediated liver damage, characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment
 - immune control:** lower HBV-DNA (<10,000 IU/mL, HBeAg negative, anti-HBe positive, ALT/AST normal, due to immune control without immune-mediated liver damage; risk of reactivation to pattern (2) especially with immunosuppression such as corticosteroids, chemotherapy (reactivation clinically resembles acute hepatitis B)
 - reactivation:** "core or precore mutant" = high HBV-DNA >100 IU/ml, HBeAg negative because of pre-core or core promoter gene mutation, anti-HBe positive, ALT/AST high, characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment

- Risk of hepatoma in HBV increases with increasing age, which is likely a surrogate for increasing liver fibrosis/cirrhosis.
- Risk of hepatoma in HCV increases only after cirrhosis develops.

Management

- counselling: 40% of men and 10% of women with perinatal infection will die from HBV-related complications
- if prolonged phase of immune-mediated damage, higher risk of liver fibrosis progression; hepatoma screening with ultrasound q6months if cirrhosis present
 - more likely in men (age >40) and women (age >50)
- consider pharmacological treatment if HBV-DNA >1,000 IU/ml if immune-mediated damage is likely to continue
- treatment goal: reduce serum HBV-DNA to undetectable level to minimize risk of drug resistance/treatment failure
- treatment options: interferon, tenofovir, entecavir, lamivudine, adefovir
- vaccinate against HAV if serology negative
- follow blood and sexual precautions

Without treatment 8-20% of those with ongoing active immune-mediated liver injury can develop cirrhosis within 5 years. In contrast, those in the immune tolerant phase with extremely high HBV-DNA levels are at minimal risk for liver fibrosis as they do not have immune-mediated liver injury.

Hepatitis D

- defective RNA virus requiring HBsAg for entry into hepatocyte, therefore infects only patients with hepatitis B, causes more aggressive disease than hepatitis B virus alone
- co-infection: acquire HDV and HBV together
 - better prognosis than superinfection (acute HDV infection on pre-existing HBV infection)
- HDV can present as fulminant hepatic failure (FHF) and/or accelerate progression to cirrhosis

HDV increases severity of hepatitis but does not increase risk of progression to chronic hepatitis.

Chronic Hepatitis B + D

Management

- low-dose interferon, response only about 20%
- liver transplant for end-stage disease

Hepatitis C Virus (HCV)

- RNA virus
- blood-borne transmission; sexual transmission is "inefficient"
- major risk factor: injection drug use
- other risk factors: blood transfusion received before 1992 (or received in developing world), tattoos, intranasal cocaine use
- clinical manifestation develops 6-8 weeks after exposure
 - symptoms mild and vague (fatigue, malaise, nausea) therefore not commonly diagnosed in acute stage

Diagnosis

- suspected on basis of elevated ALT/AST + positive serum anti-HCV
- diagnosis established by detectable HCV-RNA in serum
- virus genotype correlates with response to treatment but not prognosis
 - serum HCV-RNA inversely correlates with response to treatment
- normal transaminases can have underlying cirrhosis on biopsy, but otherwise excellent prognosis

Management

- blood-borne precautions; vaccinate for hepatitis B and A if serology negative; avoid alcohol
- clearest indication for treatment is subgroup likely to develop clinically significant liver disease: persistently elevated transaminases, liver biopsy shows fibrosis/cirrhosis and at least moderately severe necrosis/inflammation
- indicators of poor response to treatment: cirrhosis, genotype 1, high HCV-RNA, co-infection with HIV, African-American race

HCV treatment lowers the risk of hepatoma.

- alpha interferon + ribavarin aims to clear HCV infection (undetectable HCV-RNA 6 months off treatment that is maintained indefinitely), but only 50-80% success rate and side effects common therefore not all patients treated
 - alpha-interferon SC injection weekly and ribavarin PO BID
- length of treatment determined by time required for HCV-RNA to fall
 - measure HCV-RNA 1 and 3 months after starting treatment
- adverse effects: depression/fatigue, hemolysis, bone marrow suppression (monitor CBC regularly), fevers/myalgia, precipitates autoimmune diseases (rare)

Prognosis

- 80% become chronic; of these 20% evolve to cirrhosis
- risk of hepatoma increases once cirrhosis has developed
- risk factors for liver disease progression are alcohol intake, HIV co-infection, old age at diagnosis
- can cause cryoglobulinemia; associated with membranoproliferative glomerulonephritis, lymphoma

Chronic Hepatitis

Definition

- an increase in serum transaminases for >6 months

Etiology

- fat (metabolic syndrome, alcohol)
- viral (B, B+D, C; not A or E)
- drugs (methyldopa, INH, nitrofurantoin, amiodarone)
- autoimmune
- genetic (hemochromatosis, Wilson's disease, α 1-antitrypsin deficiency)

Clinical Features

- usually asymptomatic, detected incidentally
- increased AST, ALT

Treatment

- treat underlying cause as this will prevent ongoing liver injury and allow recovery

Autoimmune Chronic Active Hepatitis

- diagnosis of exclusion: rule out viruses, drugs, metabolic or genetic causes
- can be severe: 40% mortality at 6 months without treatment
- extrahepatic manifestations
 - sicca, Raynaud's, thyroiditis, Sjögren's, arthralgias
 - hypergammaglobulinemia
 - ♦ anti-smooth muscle antibody elevation is most characteristic; also elevations in anti-LKM (liver kidney microsome, especially in children)
 - less specific: elevated ANA, RF
 - ♦ can have false positive viral serology (especially anti-HCV)
- management: corticosteroids (80% respond) \pm azathioprine (without this most relapse as corticosteroids are withdrawn)

Fulminant Hepatic Failure (FHF)

- in the setting of a previously normal liver, rapid (characteristically <8 weeks) development of jaundice followed by hepatic encephalopathy
- causes: drugs (especially acetaminophen), hepatitis B (measure IgM anti-HBc because sometimes HBV-DNA and even HBsAg rapidly becomes negative), hepatitis A, hepatitis C (rare), ischemic, idiopathic
- management: correct hypoglycemia, monitor level of consciousness, prevent GI bleeding with PPI, vigilant for infection and multiorgan failure (usually requires ICU)
- consider liver biopsy before INR becomes too high
 - chief value is to exclude chronic disease, less helpful for prognosis
- liver transplant: consider early, especially if time from jaundice to encephalopathy >7 days (e.g. not extremely rapid), age <10 or >40, cause is drug or unknown, bilirubin >300 μ mol/L, INR >3.5, creatinine >200 μ mol/L

Table 17. Characteristics of the Viral Hepatitis

Hepatitis	Clinical Presentation	Definition	Communicability	Investigation	Treatment	Prognosis	Complications
Acute Viral Hepatitis	Most subclinical Prodrome: flu-like, may precede jaundice by 1-2 weeks	<6 months	Variable	AST, ALT, ALP, bilirubin	Supportive (hydrate, diet) Hospitalize if: encephalopathy, coagulopathy, severe vomiting, hypoglycemia	Poor prognosis: comorbidities, ↑ Bili, ↑ INR, ↓ Alb, hypoglycemia	Hepatocellular necrosis: AST, ALT > 10-20x normal, ALP and bilirubin minimally ↑, increased cholestasis
Virus	Transmission	Incubation	Communicability	Serology	Management	Prognosis	Complications
Hepatitis A	Fecal-oral	4-6 weeks	2-3 weeks in late incubation to early clinical phase Acute hepatitis in most adults, 10% of children	Anti-HAV (IgM)	General hygiene Treat close contacts (anti-HAV Ig) Prophylaxis for high-risk groups (HAV vaccine ± HAV Ig) unless immune	No chronicity	
Hepatitis B	Parenteral or equivalent Vertical	6 weeks-6 months	HBsAg + state highly communicable Increased during T3 or early post-partum	See Table 16	Prevention: HBV vaccine and/or hepatitis B Ig (HBIG); for needlestick, sexual contact, infants of infected mothers unless already immune	Chronicity in 20%	Hepatocellular carcinoma secondary to cirrhosis Serum sickness-like syndrome Glomerulonephritis Cryoglobulinemia Polyarteritis nodosa Porphyria cutanea tarda
Hepatitis C	Parenteral (transfusion, IDU, sexual [$<$ HBV]) 40% have no known risk factors	6-8 weeks		HCV-RNA Anti-HCV (IgG/IgM)	Prevention: no vaccine Rx: IFN + ribavirin	Chronicity in 80%, 20% of these develop cirrhosis	Hepatocellular carcinoma in 2-5% of cirrhosis per year Cryoglobulinemia
Hepatitis D	Non-parenteral (close contact in endemic areas) Parenteral (blood products, IDU)		Infectious only in presence of HBV (HBsAg required for replication)	HBsAg Anti-HDV (IgG/IgM)	Prevention: HBV vaccine	Predisposes HBV carriers to more severe hepatitis and faster progression to cirrhosis	
Hepatitis E	Fecal-oral (endemic: Africa, Asia, central America, India, Pakistan)	2-6 weeks		Anti-HEV (IgG/IgM)	Prevention: general hygiene, no vaccine	No chronicity	Mild, except in third trimester (10-20% fulminant liver failure)
Chronic Hepatitis	Epidemiology	Time Course	Diagnosis	Management	Prognosis		
Chronic Hepatitis C	50% of chronic hepatitis	At 10 years: chronic hepatitis At 20 years: cirrhosis At 30 years: HCC	Serum HCV-RNA Anti-HCV (+)	Minimize alcohol intake Strict blood precautions Vaccinate for Hep A, B HCC screen with U/S and serum alpha-fetoprotein (AFP) Rx: Pegylated interferon α -2a or 2b + ribavirin	20% progress to cirrhosis 3% of cirrhotics develop HCC		
Chronic Hepatitis B	1-2% of healthy adults with acute hepatitis B 90% if infected at birth	Replicative Phase (HBeAg +): ↑ infectivity Non-reactive Phase (anti-HBe +): ↓ infectivity		Limit alcohol intake Blood/sex precautions HCC screen Rx: interferon, lamivudine, adefovir, entecavir, tenofovir, telbivudine	If HBV-DNA: (-) wam of reactivity (+) wam of progression to cirrhosis		
Chronic Hepatitis B+D				Liver transplant for end-stage disease			

Drug-Induced Liver Disease

Table 18. Classification of Hepatotoxins

	Direct	Indirect
Example	Acetaminophen, CCl ₄	Phenytoin, INH
Dose-dependence	Usual	Unusual
Latent Period	Hours-days	Weeks-months
Host Factors	Not important	Very important
Predictable	Yes	No (idiosyncratic)

Specific Drugs

- acetaminophen
 - metabolized by hepatic cytochrome P450 system
 - can cause FHF (transaminases >1,000 U/L followed by jaundice and encephalopathy)
 - requires 10-15 g in healthy, 4-6 g in alcoholics/anticonvulsant users
 - toxicity
 - mechanism: high acetaminophen dose saturates glucuronidation and sulfation elimination pathway → reactive metabolite is formed → covalently binds to hepatocyte membrane
 - presentation:
 - ♦ first 24 hrs: nausea and vomiting usually within 4-12 hours
 - ♦ 24-48 hrs: asymptomatic but ongoing hepatic necrosis resulting in increased aminotransferases
 - ♦ >48 hrs: continued hepatic necrosis possibly complicated with FHF or resolution
 - ♦ note: potential delay in presentation in sustained-release products
 - blood levels of acetaminophen correlate with the severity of hepatic injury, particularly if time of ingestion known
 - therapy:
 - ♦ gastric lavage/emesis (if <2 hrs after ingestion)
 - ♦ oral activated charcoal
 - ♦ N-acetylcysteine (NAC, Mucomyst®) can be given PO or IV, most effective within 8-10 hours of ingestion, but should be given no matter when time of ingestion
 - promotes hepatic glutathione synthesis
 - ♦ no recorded fatal outcomes if NAC given before increase in transaminases
- chlorpromazine
 - cholestasis in 1% after 4 weeks; often with fever, rash, jaundice, pruritus and eosinophilia
- INH (isoniazid)
 - 20% develop elevated transaminases but <1% develop clinically significant disease
 - susceptibility to injury increases with age
- methotrexate
 - rarely cause cirrhosis, increased risk in the presence of obesity, diabetes, alcoholism (i.e. with underlying risk for pre-existing fatty liver)
 - scarring develops without symptoms or changes in liver enzymes, therefore biopsy may be needed in long-term treatment
- amiodarone
 - can cause same histology and clinical outcome as alcoholic hepatitis
- others
 - azoles, statins, methyl dopa, phenytoin, PTU, rifampin, sulfonamides, tetracyclines
- herbs
 - chaparral, chinese herbs (e.g. germander, comfrey, bush tea)

Wilson's Disease

Definition

- autosomal recessive defect in copper metabolism (gene ATP7B)

Pathology

- impaired transport of copper from hepatic cytoplasm to endoplasmic reticulum, leading to decreased copper available for production of ceruloplasmin and decreased copper excretion via bile excretion

Clinical Manifestations

- liver: cirrhosis, chronic active hepatitis, acute hepatitis, fulminant liver failure, low risk of HCC
- eyes: Kayser-Fleischer rings (copper deposits in Descemet's membrane); more common in patients with CNS involvement, only present in 50% if only liver involvement
- CNS: basal ganglia (wing flapping tremor, Parkinsonism), cerebellum (dysarthria, dysphagia, incoordination, ataxia), cerebrum (psychosis, affective disorder)
- kidneys: Fanconi's syndrome (proximal tubule transport defects) and stones
- blood: intravascular hemolysis; may be initial presentation in fulminant hepatitis
- joints: arthritis, bone demineralization, calcifications

Investigations

- suspect if increased liver enzymes with clinical manifestations at young age (<30); especially combination of liver disease with trauma, dystonia, psychiatric symptoms
- screening tests:
 1. reduced serum ceruloplasmin (<50% of normal)
 2. Kayser-Fleischer rings (usually require slit-lamp examination)
 3. increased urinary copper excretion
- gold standard:
 1. increased copper on liver biopsy by quantitative assay
 2. genetic analysis imperfect as many mutations in ATP7B are possible

Treatment

- chelators (penicillamine, trientine): increased urinary excretion of copper
- tetrathiomolybdate preferred if neurological involvement
- zinc acetate
 - blocks intestinal absorption of copper
 - sequesters excess copper
- screen relatives
- liver transplant in severe cases

Clinical Manifestations of Wilson's Disease

ABCD

Asterixis
Basal ganglia degeneration: suspect if parkinsonian features in the young
Ceruloplasmin ↓
Cirrhosis
Corneal deposits (KF ring)
Copper
Dementia

Hemochromatosis

Definition

- excess iron storage, which causes multiorgan system dysfunction with total body stores of iron increased to 20-40 g (normal 1 g)

Etiology

- primary hemochromatosis
 - due to common recessive gene (HFE, 5%); 1/400 patients are homozygotes
 - results in ongoing gut absorption of iron despite adequate iron stores
- secondary hemochromatosis
 - parenteral iron overload (e.g. transfusions)
 - chronic hemolytic anemia: thalassemia, pyruvate kinase deficiency
 - excessive iron intake

Not 100% penetrant: not all with homozygous gene defect have clinical iron overload.

Clinical Features

- usually presents with trivial elevation in serum transaminases
- liver: cirrhosis (30%), HCC (200x increased risk) – most common cause of death (1/3 of patients)
- pancreas: diabetes, chronic pancreatitis
- skin: bronze or grey (due to melanin, not iron)
- heart: dilated cardiomyopathy
- pituitary: hypogonadotropic hypogonadism (impotence, decreased libido, amenorrhea)
- joints: arthralgia (any joint but especially MCP joints), chondrocalcinosis

Investigations

- screening for individuals with clinical features and/or family history (1/4 chance of sibling having the disease)
 - transferrin saturation (free Fe/TIBC) >50%
 - serum ferritin >400 ng/ml
 - HFE gene analysis: 90% of idiopathic hemochromatosis have homozygous C282Y gene mutation
- liver biopsy (to define degree of iron overload and to detect cirrhosis)
 - usually indicated if age >40, elevated ALT/AST, or ferritin >1000
- HCC screening if cirrhosis

Ferritin may never normalize if other causes of high ferritin present (e.g. fatty liver from metabolic syndrome or alcohol).

Treatment

- phlebotomy: weekly or q2weeks then lifelong maintenance phlebotomies q2-6 months
- deferoxamine if phlebotomy contraindicated (e.g. cardiomyopathy, anemia)
- primary hemochromatosis responds well to phlebotomy
- secondary hemochromatosis usually requires chelation therapy

Prognosis

- normal life expectancy if treated before the development of cirrhosis or diabetes

Alcoholic Liver Disease

13 g ethanol = 1 beer = 4 oz wine = 1.5 oz liquor

Types of Lesions

- fatty liver (all alcoholics): always reversible if alcohol stopped
- alcoholic hepatitis (35% of alcoholics): usually reversible if alcohol stopped
- cirrhosis (10-15% of alcoholics): potentially irreversible

Pathophysiology

- several mechanisms, poorly understood
- ethanol oxidation to acetaldehyde:
 - reduces NAD to NADH; increased NADH decreases ATP supply to liver, impairing lipolysis so fatty acid and triglycerides accumulate in liver
 - binds to hepatocytes evoking an immune reaction
- ethanol increases gut permeability leading to increased bacterial translocation
- alcohol metabolism causes:
 - relative hypoxia in liver zone III > zone I
 - necrosis and hepatic vein sclerosis
- histology of alcoholic hepatitis:
 - ballooned (swollen) hepatocytes often containing Mallory bodies, characteristically surrounded by neutrophils
 - large fat globules
 - fibrosis: space of Disse and perivenular

Biopsy + Histology of Alcoholic Hepatitis (triad)

- Hepatocyte necrosis with surrounding inflammation in zone III
- Mallory bodies (intracellular eosinophilic aggregates of cytokeratins)
- Chicken-wire fibrosis (network of intralobular connective tissue surrounding cells and venules)

GI Complications of Alcohol Abuse

Esophagus

- Mallory-Weiss tear
- Esophageal varices (secondary to portal hypertension)

Stomach

- Alcoholic gastritis

Pancreas

- Acute pancreatitis
- Chronic pancreatitis

Liver

- Alcoholic hepatitis
- Fatty liver
- Cirrhosis
- Hepatic encephalopathy
- Portal hypertension (secondary to cirrhosis)
- Ascites (secondary to cirrhosis)
- HCC (secondary to cirrhosis)

Clinical Features

- threshold for cirrhosis is >20-40 g EtOH/day in females or >40-80 g EtOH/day in males x 10-20 years; cirrhosis develops in about 5% of those who consume this amount daily on a continuous basis; cirrhosis risk increases with amount of alcohol consumed above threshold
- clinical findings do not predict type of liver involvement
- fatty liver:
 - mildly tender hepatomegaly; jaundice rare
 - mildly increased transaminases <5x normal
- alcoholic hepatitis:
 - variable severity: mild to fatal liver failure
 - mild: stops drinking because feels unwell, resumes when feeling better (if assessed, findings of hepatitis, potentially mild jaundice and mildly elevated INR)
 - severe: stops drinking but feels unwell, low grade fever, RUQ discomfort – mimics RLL pneumonia and cholecystitis
- blood tests are non-specific, but in general:
 - AST:ALT > 2:1 (usually <300)
 - increased GGT
 - CBC: increased MCV (mean corpuscular volume), increased WBC
- prognosis determined by degree of liver failure (INR elevation, bilirubin elevation)

Treatment

- alcohol cessation (see [Psychiatry](#), PS20)
 - Alcoholics Anonymous, disulfiram, naltrexone, acamprosate
- multivitamin supplements (especially thiamine)
- caution with drugs metabolized by the liver
- prednisone 40 mg OD x 28 days (no taper) in subgroup with elevated bilirubin and INR, or if encephalopathy; but contraindicated if GI bleeding, renal failure, infection
- pentoxifylline decreases TNF, shown in one trial to reduce renal failure but not mortality in alcoholic hepatitis, now widely used due to favourable side effect profile

Prognosis

- fatty liver: complete resolution with cessation of EtOH intake
- alcoholic hepatitis mortality
 - immediate: 30%-60% in the first 6 months if severe
 - with continued alcohol: 70% in 5 years
 - with cessation: 30% in 5 years

Non-Alcoholic Fatty Liver Disease (NAFLD)

Etiology/Epidemiology

- spectrum of disorders characterized by macrovesicular hepatic steatosis
- most common cause of liver disease in North America

Pathophysiology

- pathogenesis not well elucidated; insulin resistance implicated as key mechanism, leading to hepatic steatosis
- changes indistinguishable from those of alcoholic hepatitis despite negligible history of alcohol consumption

Risk Factors

- likely a component of the metabolic syndrome along with type II diabetes, hypertension, hypertriglyceridemia
- rapid weight loss or weight gain

Clinical Features/Investigations

- often asymptomatic
- may present with fatigue, malaise and vague RUQ discomfort
- elevated serum triglyceride/cholesterol levels and insulin resistance
- elevated serum AST, ALT \pm ALP; AST/ALT <1
- presents as echogenic liver texture on ultrasound
- liver biopsy diagnostic but often necessary only for prognosis

Management

- no proven effective therapy other than gradual weight loss
- modification of risk factors is generally recommended, particularly gradual weight reduction
- optimization of therapy for diabetes, hyperlipidemia, hypertension likely helpful

Prognosis

- better prognosis than alcoholic hepatitis
 - $<25\%$ progress to cirrhosis over a 7-10 year period
- risk of progression increases if inflammation or scarring alongside fat infiltration (non-alcoholic steatohepatitis)
- other clinical indicators of unfavourable prognosis: diabetes, age

Cirrhosis

Definition

- liver damage characterized by diffuse distortion of the basic architecture and replacement with scar tissue
- Stage 1 cirrhosis is compensated and asymptomatic, can last for 10-20 years with almost normal life expectancy
- Stage 2 cirrhosis is the onset of first decompensation, typically development of liver failure, ascites or variceal bleed

Fibrosis may regress and disappear if cause of liver injury is treated or resolves.

Usual causes of death in cirrhosis: renal failure (hepatorenal syndrome), sepsis, GI bleed, or HCC.

Etiology

- fatty liver (alcohol, metabolic syndrome)
- chronic viral hepatitis (B, B+D, C; not A or E)
- autoimmune hepatitis
- hemochromatosis
- α 1-antitrypsin deficiency
- primary biliary cirrhosis
- chronic hepatic congestion
 - cardiac cirrhosis (chronic right heart failure, constrictive pericarditis)
 - hepatic vein thrombosis (Budd-Chiari)
- idiopathic
- rare – Wilson's disease, Gaucher's disease

Diagnosis

- definitive diagnosis is histologic (liver biopsy)
- other tests may be suggestive:
 - blood work: fall in platelet count <150 is the earliest finding, followed many years later with rise in INR, fall in albumin, rise in bilirubin, fall in glucose level (pre-terminal event)
 - imaging:
 - ♦ U/S is the primary imaging modality but only finds advanced cirrhosis
 - ♦ CT to look for varices, nodular liver texture, splenomegaly, ascites
 - gastroscopy: varices or portal gastropathy

Management

- treat underlying disorder
- decrease insults (e.g. alcohol cessation, hepatotoxic drugs)
- follow patient for complications (esophageal varices, ascites, HCC defines stage 2 cirrhosis)
- prognosis: Child-Pugh Score (see Table 19)
- liver transplantation for end-stage disease if no alcohol for >6 months; use MELD stratification
 - MELD (Model for End Stage Liver Disease)
 - ♦ used to stratify patients on transplant list
 - ♦ score <14 predicts 3 month survival
 - ♦ based on creatinine, INR and total bilirubin

Table 19. Child-Pugh Score and Interpretation

Classification	1	2	3
Serum bilirubin (μ mol/L)	<34	34-51	>51
Serum albumin (g/L)	>35	28-35	<28
Presence of ascites	Absent	Controllable	Refractory
Encephalopathy	Absent	Minimal	Severe
INR	<1.7	1.7-2.3	>2.3
Interpretation			
Points	Class	Life Expectancy	Perioperative Mortality
5-6	A	15-50 years	10%
7-9	B	Candidate for transplant	30%
10-15	C	1-3 months	82%
Score: 5-6 (Child's A), 7-9 (Child's B), 10-15 (Child's C)			

*Note: Child's classification is rarely used for shunting, but is still useful to quantitate the severity of cirrhosis

Complications

- hematologic changes in cirrhosis
 - pancytopenia from hypersplenism: platelets first, then WBC, then hemoglobin
 - decreased clotting factors resulting in elevated INR, thus tendency for bruising and bleeding
- renal failure in cirrhosis
 - classifications
 - ♦ pre-renal (usually due to over-diuresis)
 - ♦ acute tubular necrosis (ATN)
 - ♦ hepatorenal syndrome (HRS)
 - Type I: sudden and acute renal failure in the setting of pre-existing type II HRS
 - Type II: gradual increase in creatinine with worsening liver function
 - e.g. creatinine doubling over years
 - hepatorenal syndrome can occur at any time in severe liver disease, especially after:
 - ♦ overdiuresis or dehydration, such as diarrhea, vomiting, etc.
 - ♦ GI bleed
 - ♦ sepsis

Cirrhosis Complications

VARICES

Varices
Anemia
Renal failure
Infection
Coagulopathy
Encephalopathy
Sepsis

- hepatorenal syndrome vs. pre-renal failure – difficult to differentiate:
 - ♦ similar blood and urine findings, (see [Nephrology](#), NP19)
 - ♦ urine sodium very low in hepatorenal; low in prerenal
 - ♦ intravenous fluid challenge (giving volume expanders improves prerenal failure but not hepatorenal syndrome)
 - ♦ treatment for hepatorenal syndrome is generally unsuccessful at improving long term survival
 - ♦ octreotide + midodrine + albumin (increased renal blood flow by increased systemic vascular resistance)
 - ♦ definitive treatment is liver transplant
- hepatopulmonary syndrome (HPS)
 - clinical triad:
 1. liver disease
 2. increased alveolar-arterial gradient while breathing room air
 3. evidence for intrapulmonary vascular abnormalities
 - majority of cases due to cirrhosis, though can be due to other chronic liver diseases, such as non-cirrhotic portal hypertension
 - thought to arise from ventilation-perfusion mismatch, intrapulmonary shunting and limitation of oxygen diffusion, failure of damaged liver to clear circulating pulmonary vasodilators, vs. production of a vasodilating substance by the liver
 - clinical features:
 - ♦ hyperdynamic circulation with cardiac output >7 L/min at rest and decreased pulmonary + systemic resistance (intrapulmonary shunting)
 - ♦ dyspnea, platypnea (increase in dyspnea in upright position, improved by recumbency) and orthodeoxia (desaturation in the upright position, improved by recumbency)
 - ♦ diagnosis via contrast-enhanced (inject air bubbles into peripheral vein) echocardiography (air bubbles appear in left ventricle after third heartbeat; normal = no air bubbles; in ventricular septal defect air bubbles seen <3 heartbeats)
 - ♦ only proven treatment is liver transplantation

Figure 12. Clinical Features of Liver Disease

Hepatocellular Carcinoma (HCC)

- see [General Surgery](#), GS42

Liver Transplant

- see [General Surgery](#), GS44

Portal Hypertension

Definition

- pressure gradient between hepatic vein pressure and wedged hepatic vein pressure (corrected sinusoidal pressure) >5 mmHg

Pathophysiology

- 3 sites of increased resistance (remember pressure = flow x resistance)
 - pre-sinusoidal (e.g. portal vein thrombosis, schistosomiasis, sarcoidosis)
 - sinusoidal (e.g. cirrhosis, alcoholic hepatitis)
 - post-sinusoidal (e.g. right-sided heart failure, hepatic vein thrombosis, veno-occlusive disease, constrictive pericarditis)

**Portal Hypertension****Signs**

Esophageal varices
Melena
Splenomegaly
Ascites
Hemorrhoids

Management

β -blockers
Nitrates
Shunts [e.g. transjugular intrahepatic portosystemic shunt (TIPS)]

Complications

- GI bleeding from varices in esophagus, less commonly in stomach, even less frequently from portal hypertensive gastropathy
- ascites
- hepatic encephalopathy
- thrombocytopenia
- renal dysfunction
- sepsis
- arterial hypoxemia

Management

- β -blockers (propranolol, nadolol) decreases risk of bleeding from varices
- transjugular intrahepatic portosystemic shunt (TIPS): to decrease portal venous pressure
 - shunt between portal and hepatic vein via percutaneous puncture of portal vein, and (central) hepatic vein via transjugular vein catheterization
 - can be used to stop acute bleeding or prevent rebleeding or treat ascites
 - shunt usually remains open for <1 year
 - complications: hepatic encephalopathy, deterioration of hepatic function
 - contraindicated with severe liver dysfunction
- other surgically created shunts (rare): portocaval, distal spleno-renal (Warren shunt)

**Hepatic Encephalopathy****Definition**

- acute neuropsychiatric syndrome secondary to liver disease

Pathophysiology

- porto-systemic shunt around hepatocytes and decreased hepatocellular function increases toxin (believed to be ammonia from gut, mercaptans, fatty acids, amino acids) delivery to brain

Precipitating Factors

- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)
- drugs (narcotics, CNS depressants)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- infection (spontaneous bacterial peritonitis)
- deterioration in hepatic function or superimposed liver disease

Stages

- I: apathy, restlessness, reversal of sleep-wake cycle, slowed intellect, impaired computational abilities, impaired handwriting
- II: asterixis, lethargy, drowsiness, disorientation
- III: stupor (rousable), hyperactive reflexes, extensor plantar responses
- IV: coma (response to painful stimuli only)

Investigations

- clinical diagnosis: supported by laboratory findings and exclusion of other neuropsychiatric diseases
- rule out:
 - non-liver-related neuropsychiatric disease in a patient with liver problems (e.g. alcohol withdrawal or intoxication, sedatives, subdural hematoma, metabolic encephalopathy)
 - causes of metabolic encephalopathy (e.g. renal failure, respiratory failure, severe hyponatremia, hypoglycemia)
- characteristic EEG findings: diffuse (non-focal), slow, high amplitude waves

Treatment

- treat underlying precipitating factors
- decrease generation of nitrogenous compounds
 - decrease dietary protein to 50 g/day; vegetable protein is better tolerated than animal protein
 - lactulose: titrated to achieve 2 to 3 soft stools per day
 - ♦ prevents diffusion of NH_3 (ammonia) from the colon into blood by lowering pH and forming non-diffusible NH_4 (ammonium)
 - ♦ serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
 - ♦ also acts as a laxative to eliminate nitrogen-producing bacteria from colon
- if inadequate response with lactulose, may try antibiotics
 - broad-spectrum antibiotics (metronidazole, rifaximin) eliminate ammonia producing bacteria from bowel lumen
- avoid causing severe diarrhea with lactulose to decrease fluid/electrolyte problems
- best acute treatment in comatose patient is tap water enemas

**Precipitating Factors for Hepatic Encephalopathy****Hepatics**

Hemorrhage in GI tract/Hypokalemia
Excess dietary protein
Paracentesis
Alkalosis/Anemia
Trauma
Infection
Colon surgery
Sedatives

Ascites

Definition

- accumulation of excess fluid in the peritoneal cavity

Etiology

Table 20. Serum-Ascites Albumin Gradient as an Indicator of the Causes of Ascites

Serum [Alb] – Ascitic [Alb] >11 g/L (1.1 g/dL) Portal Hypertension Related	Serum [Alb] – Ascitic [Alb] <11 g/L (1.1 g/dL) Nonportal Hypertension Related
Cirrhosis/severe hepatitis	Peritoneal carcinomatosis
Chronic hepatic congestion (right heart failure, Budd-Chiari)	TB
Massive liver metastases	Pancreatic disease
Myxedema	Serositis
	Nephrotic syndrome*

* In nephrotic syndrome: decreased serum [Alb] to begin with therefore gradient not helpful

Pathogenesis

- increased portal pressure and low oncotic pressure (e.g. low serum albumin) drives sodium/water out of the splanchnic portal circulation into abdominal cavity
- key factor in pathogenesis is increased sodium (and water) retention by the kidney
 - “underfill hypothesis”: circulation underfilling because of fluid leaving circulation (secondary to high portal pressure, low oncotic pressure)
 - “overflow hypothesis”: direct effect of cirrhosis on kidney
 - peripheral arteriolar vasodilation theory: incorporates both theories (most popular)
- cirrhosis via unknown factors causes splanchnic vasodilation via nitric oxide, increasing vascular capacitance, which is underfilled relative to its capacity, but overfilled as compared to before the onset of vasodilation (i.e. volume to capacitance ratio low, but absolute volume is high)

Diagnosis

- abdominal ultrasound
- physical exam (clinically detectable when >500ml):
 - bulging flanks, shifting dullness, fluid-wave test positive
 - most sensitive sign: ankle swelling

Investigations

- diagnostic paracentesis
 - 1st aliquot: cells and differential
 - 2nd aliquot: chemistry (esp. albumin, but also protein, amylase if pancreatitis, TG if turbid and suspect chylous ascites)
 - 3rd aliquot: C&S, Gram stain
 - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

Treatment

- for non-refractory ascites:
 - Na restriction (daily sodium intake <2 grams)
 - diuretics: spironolactone, furosemide
 - aim for daily weight loss 0.5-1 kg if concomitant peripheral edema (which is mobilized quicker than ascitic fluid), more rapid weight loss increases risk of renal failure
 - double diuretic dose every 2-4 weeks to achieve aim
- for refractory ascites (diuretics inadequate or intolerated):
 - therapeutic paracentesis indicated
 - IV albumin (not indicated if <5 L removed by paracentesis)
 - TIPS usually provides temporary benefit but no survival benefit
 - liver transplantation should be considered in every case, since development of ascites in cirrhosis indicates 50% death rate in 3 years

Complication: Bacterial Peritonitis

- primary/spontaneous bacterial peritonitis (SBP)
 - complicates ascites, does not cause it (occurs in 10% of cirrhotic ascites), higher risk in GI bleed
 - 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
 - fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy
 - Gram-negatives compose 70% of pathogens: *E. coli* (most common), *Streptococcus*, *Klebsiella*

Secondary bacterial peritonitis (as opposed to primary bacterial peritonitis) usually results from a perforated viscus or surgical manipulation.

Primary Prophylaxis of Spontaneous Bacterial Peritonitis Delays Hepatorenal Syndrome and Improves Survival in Cirrhosis

Gastroenterology 2007; 133:818-24.

Study: RCT, double-blinded study with 1 year follow-up.

Population: 68 patients with cirrhosis, ascites, ascitic fluid protein <15 g/L and impaired renal function or severe liver failure.

Intervention: General, regional or combined anesthesia to patients undergoing a surgical procedure.

Main Outcome: Norfloxacin versus placebo.

Results: There was a significant reduction of patients developing spontaneous bacterial peritonitis SBP (6% vs. 30%, $p=0.02$) and spontaneous bacteremia (0% vs. 12%, $p=0.05$) with norfloxacin therapy. There were significantly fewer patients who developed all-cause renal failure (7 vs. 16, $p=0.03$) and hepatorenal syndrome with norfloxacin therapy. Probability of survival at 3 months (94% vs. 62%, $p=0.02$) and 1 year (60% vs. 48%, $p=0.003$) were high in patients treated with norfloxacin.

Conclusion: Primary prophylaxis with norfloxacin in patients with advanced cirrhosis reduced SBP, HRS, and improved 1 year survival.

- diagnosis
 - absolute neutrophil count in peritoneal fluid $>0.25 \times 10^9$ cells/L (250 cells/mm³) or WBC count $>0.5 \times 10^9$ cells/L (500 cells/mm³)
 - Gram stain positive in only 10-50% of patients
 - culture positive in <80% of patients (not needed for diagnosis)
- treatment
 - IV antibiotics (cefotaxime 2 g q12 h is the treatment of choice for 5-10 days; modify if response inadequate, culture shows resistant organisms)
 - prophylaxis long-term indicated after recovery from one episode of SBP, prophylaxis short term if GI bleeding in cirrhosis, with daily norfloxacin or TMP-SMX for 5-7 days may decrease the frequency of recurrent SBP, use if GI bleeding/previous SBP
 - IV albumin (1.5 g/kg first dose, 1 g/kg day 3) decreases mortality by lowering risk of acute renal failure

Biliary Tract

Jaundice

- see Table 21, Figures 13 and 14

Signs and Symptoms

- dark urine, pale stools – suggests that bilirubin elevation is from direct fraction
- pruritus – suggests chronic disease
- abdominal pain – suggests biliary tract obstruction from stone or pancreatic tumour (obstructive jaundice)
- painless jaundice – think of pancreatic cancer

Investigations

- blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin), amylase
- U/S for evidence of bile duct obstruction (e.g. bile duct dilation)
- direct bile duct visualization
 - magnetic resonance cholangiopancreatography (MRCP) – non-invasive
 - endoscopic retrograde cholangiopancreatography (ERCP) – invasive, most accurate, allows for therapeutic intervention
 - percutaneous transhepatic cholangiography (PTC) – if ERCP fails, if obstruction is in liver

Table 21. Classification of Jaundice

I. Predominantly Unconjugated Hyperbilirubinemia

1. Overproduction
 - Hemolysis
 - Ineffective erythropoiesis (megaloblastic anemias, others)
2. Decreased hepatic uptake
 - Gilbert's syndrome
 - Drugs (e.g. rifampin)
3. Decreased conjugation
 - Drug inhibition (e.g. chloramphenicol)
 - Crigler-Najjar syndromes type I and II
 - Neonatal jaundice
 - Gilbert's syndrome

II. Predominantly Conjugated Hyperbilirubinemia

1. Impaired hepatic secretion
 - Familial disorders (e.g. Rotor syndrome, Dubin-Johnson syndrome, cholestasis of pregnancy)
 - Hepatocellular disease – by far the most common
 - Drug-induced cholestasis (e.g. oral contraceptives, chlorpromazine)
 - Primary biliary cirrhosis (PBC)
 - Primary sclerosing cholangitis (PSC)
 - Sepsis
 - Post-operative
2. Extrahepatic biliary obstruction
 - Intraductal obstruction
 - Gallstones
 - Biliary stricture
 - Parasites
 - Malignancy (cholangiocarcinoma)
 - Sclerosing cholangitis
 - Extraductal obstruction
 - Malignancy (e.g. pancreatic cancer, lymphoma)
 - Metastases in peri-portal nodes
 - Inflammation (e.g. pancreatitis)

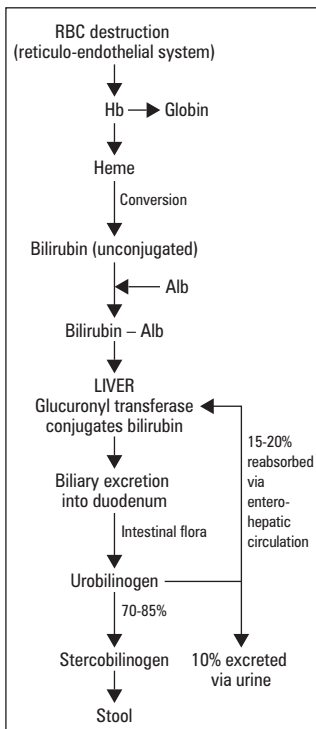

Figure 13. Production and Excretion of Bilirubin

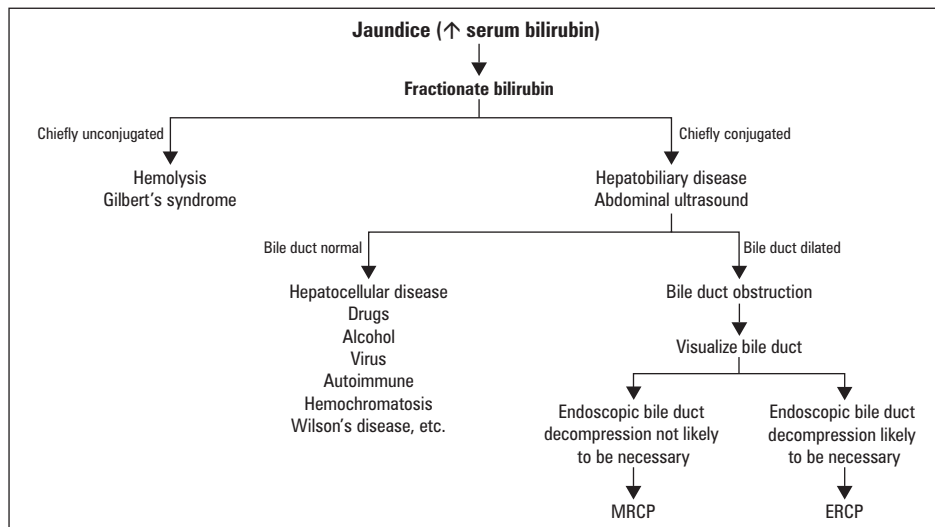

Figure 14. Approach to Jaundice

Gilbert's Syndrome

Definition

- mild decrease in glucuronyltransferase activity leading to defective conjugation of bilirubin

Etiology/Epidemiology

- some patients have decreased hepatobiliary uptake
- affects 7% of population, especially males
- autosomal dominant, 70% due to a mutation in the UGT gene

Signs and Symptoms

- presents in teens-20s, often an incidental finding
- only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting; no other clinical implications

Treatment

- none indicated (entirely benign)

Gilbert's Syndrome vs. Crigler-Najjar Syndrome

Gilbert's Syndrome: mild decrease in glucuronyltransferase activity

Crigler-Najjar Syndrome: complete deficiency of glucuronyltransferase

Sclerosing Cholangitis

Definition

- inflammation of biliary tree (intra and/or extrahepatic bile ducts) leading to scarring and obliteration

Etiology

- primary/idiopathic
 - most common
 - associated with IBD in up to 70% (usually male)
 - one of the most common indications for transplant
- secondary – less common
 - long-term choledocholithiasis
 - cholangiocarcinoma
 - surgical/traumatic injury (iatrogenic)
 - contiguous inflammatory process
 - post-ERCP
 - associated with HIV/AIDS (“HIV cholangiopathy”)

Signs and Symptoms

- often insidious, may present with fatigue and pruritus
- may present with signs of episodic bacterial cholangitis secondary to biliary obstruction

**ERCP**

- Absence of narrowing in PBC
- Narrowing of intra and extrahepatic ducts in PSC

Diagnosis

- increased ALP (hallmark), less often increased bilirubin
- mildly increased AST, usually <300 U/L
- p-ANCA (30-80%), elevated IgM (40-50%)
- ERCP shows narrowing of bile ducts, both intrahepatic and extrahepatic bile ducts
 - if intrahepatic narrowing only, do antimitochondrial antibody to rule out PBC

Complications

- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%): difficult to diagnose and treat

Management

- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma
- endoscopic sphincterotomy, biliary stent in selected cases of dominant CBD stricture
- antibiotics for cholangitis
- suppurative cholangitis requires emergency drainage of pus in CBD
- liver transplantation appears the best treatment for advanced sclerosing cholangitis (nearly 90% 1 year survival; mean follow-up from time of diagnosis to need for transplant is 10 years)
- ursodiol (previously recommended) may actually increase mortality

Prognosis

- unfavourable regardless of treatment
- mean survival after diagnosis remains 4-10 years

Primary Biliary Cirrhosis (PBC)

Definition

- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

Etiology/Epidemiology

- likely autoimmune (associated with Sjögren's syndrome, scleroderma, CREST syndrome, RA, thyroiditis)
- affects mainly middle-aged women (M:F = 1:9)

Signs and Symptoms

- often asymptomatic
- earliest symptoms: pruritus, fatigue
- after several months-years: jaundice and melanosis (darkening skin) and other signs of cholestasis
- eventually: hepatocellular failure, portal hypertension, ascites
- high incidence of osteoporosis

Investigations

- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA) (95% specificity)
- increased serum cholesterol → xanthelasma, xanthomas (mild increase in LDL, larger increase in HDL)
- liver biopsy confirms diagnosis and stages severity
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- recently described "overlap" syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis

Clinical Course

- can be fatal, although not all asymptomatic patients show progression

Treatment

- treat with ursodiol (less frequently colchicine, methotrexate)
- cholestyramine (for pruritus and hypercholesterolemia)
- calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
- monitor for thyroid disease
- liver transplant if disease severe, progressive

Table 22. Primary Sclerosing Cholangitis vs. Primary Biliary Cirrhosis

	Primary Sclerosing Cholangitis	Primary Biliary Cirrhosis
Predominant Gender	Male	Female
Associated Comorbidities	IBD Colitis	Other autoimmune disorders (Sjögren's, CREST, RA)
Affected Ducts	Both intra- and extra-hepatic	Intrahepatic only
Investigations	ERCP/MRCP (narrowing of ducts visualized)	Anti-mitochondrial antibodies, IgM, increased lipids, liver biopsy (absence of duct narrowing on ERCP)

Secondary Biliary Cirrhosis

Definition

- cirrhosis from prolonged partial or total obstruction of major bile ducts

Etiology

- acquired: post-op strictures, chronic pancreatitis, sclerosing cholangitis, stone in bile duct
- congenital: cystic fibrosis (CF), congenital biliary atresia, choledochal cysts

Diagnosis

- cholangiography and liver biopsy

Treatment

- treat obstruction, give antibiotics for cholangitis prophylaxis

Ascending Cholangitis

Definition

- infection of the biliary tree

Etiology

- stasis in the biliary tract due to obstruction or stricture (usually from previous cholecystectomy)
- infection originates in the duodenum or spreads hematogenously from the portal vein
- bacteria
 - *E. coli*, *Klebsiella*, *Enterobacter*, *Enterococcus*
 - co-infection with *Bacteroides* and *Clostridia* can occur

Signs and Symptoms

- Charcot's Triad: fever, RUQ pain, jaundice (50-70%)
- Reynold's Pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, confusion

Diagnosis

- increased WBC
- usually increased ALP, ALT, less often increased bilirubin
- blood culture
- abdominal U/S – CBD dilation, stones

Treatment

- antibiotic therapy – broad spectrum to cover Gram-negatives and *Enterococcus*
 - ampicillin + gentamicin OR 3rd generation cephalosporin OR imipenem
 - consider metronidazole to cover anaerobes, especially if previous CBD manipulation
- ERCP – diagnosis and therapeutic sphincterotomy, stone extraction

Prognosis

- good with effective drainage and antibiotics in mild to moderate cases
- high mortality (~50%) in patients with Reynold's Pentad

Charcot's Triad

- RUQ pain
- Fever
- Jaundice

Reynold's Pentad

- Charcot's triad
- Hypotension
- Confusion

Pancreas

Pancreatic Enzyme Abnormalities

Pancreatic Enzymes

- Amylase
- Lipase
- Trypsin
- Chymotrypsin

When serum amylase >5x normal, the cause is almost always pancreatitis or renal disease.

Causes of Increased Serum Amylase

- pancreatic disease
 - pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
 - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
 - cancer (lung, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
 - macroamylasemia

Causes of Increased Serum Lipase

- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
 - macrolipasemia
 - renal failure

Acute Pancreatitis

When thinking about the causes of acute pancreatitis remember: **I GET SMASHED**, but vast majority due to gallstones or ethanol

Etiology

Idiopathic: thought to be hypertensive sphincter or microlithiasis

Gallstones (45%)

Ethanol (35%)

Tumours: pancreas, ampulla, choledochocoele

Scorpion stings

Microbiological

- bacterial: *Mycoplasma*, *Campylobacter*, TB, *M. avium intracellulare*, *Legionella*, leptospirosis
- viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
- parasites: ascariasis, clonorchiasis, echinococcosis

Autoimmune: SLE, polyarteritis nodosa (PAN), Crohn's

Surgery/trauma

- manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer

Hyperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), hypercalcemia, hypothermia

Emboli or ischemia

Drugs/toxins

- azathioprine, mercaptopurine, furosemide, estrogens, methyl dopa, H₂-blockers, valproic acid, antibiotics, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)

Pathogenesis

- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis this is due to mechanical obstruction of the pancreatic duct by stones, in ethanol unknown
- in rare genetic diseases, which may be a model for ethanol, key problem is a mutation preventing the physiological trypsin breakdown required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis; mutation in SPINK 1 gene which normally inhibits activated trypsin)

Pathology

- mild (interstitial)
 - peri-pancreatic fat necrosis
 - interstitial edema
- severe (necrotic)
 - extensive peri-pancreatic and intra-pancreatic fat necrosis
 - parenchymal necrosis and hemorrhage → infection in 60%
 - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)

Rule out other causes with specific treatment before making diagnosis of acute pancreatitis, which can only be treated by supportive means.

- severity of clinical features may not always correlate with pathology
- 3 phases:
 - local inflammation + necrosis → hypovolemia
 - systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
 - local complications 2 weeks after presentation → pancreatic sepsis/abscess

Signs and Symptoms

- pain: epigastric, noncolicky, constant, can radiate to back, may improve when leaning forward (Ingelfinger's sign)
- tender rigid abdomen; guarding
- nausea and vomiting
- abdominal distention from paralytic ileus
- fever: chemical, not due to infection
- jaundice: compression or obstruction of bile duct
- Cullen's/Grey-Turner's signs
- tetany: transient hypocalcemia
- hypovolemic shock: can lead to renal failure
- acute respiratory distress syndrome
- coma

Investigations

- increased serum pancreatic enzymes: amylase, lipase (more specific)
- ALT >100 strongly suggests biliary pancreatitis
- increased WBC, glucose; low calcium
- imaging: CT most useful for diagnosis and prognosis
 - x-ray: "sentinel loop" (dilated proximal jejunum), calcification and "colon cut-off sign" (colonic spasm)
 - U/S: best for evaluating biliary tree (67% sensitivity, 100% specificity)
 - CT scan with IV contrast: useful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
 - ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumour, pancreas divisum

Prognosis

- usually a benign, self-limiting course, single or recurrent
- occasionally severe leading to:
 - shock
 - pulmonary edema
 - multi-organ dysfunction syndrome
 - GI ulceration due to stress
 - death
- mortality according to Ranson's criteria (see sidebar)
 - ≤2 criteria = <5% mortality
 - 3-4 criteria = 15-20%
 - 5-6 criteria = 40%
 - ≥7 criteria = >99%

Treatment

- goals:
 - (1) hemodynamic stability
 - (2) analgesia
 - (3) oxygen
 - (4) stop progression of damage – difficult
 - (5) treat local and systemic complications
- antibiotics controversial except in documented infection (use cephalosporins, imipenem)
- aspirate necrotic areas of pancreas to diagnose infection; drain if infected
- IV fluids (crystalloid or colloid)
 - beware third spacing of fluid, monitor urine output carefully
- NG suction (rests pancreas) if vomiting, stomach very dilated
- endoscopic sphincterotomy if gallstone pancreatitis
- nutritional support: nasoenteric jejunal feeding tube or TPN if cannot tolerate enteric feeds
 - recent evidence supports nasogastric enteral (or oral if feasible) feeds
- no benefit: glucagon, atropine, trasyolol, H₂-blockers, peritoneal lavage
- follow clinically and CT/ultrasound to exclude complications
- chief role of surgery is to drain fluid in the case of infected pancreatic necrosis (try to delay for >2 weeks to allow demarcation between viable and necrotic tissue)

Increased amylase

- Sensitive, not specific

Increased lipase

- Higher sensitivity and specificity
- Stays elevated longer

Ranson's Criteria: Prognostic Indicator of Mortality in Pancreatitis Not due to Gallstones (criteria slightly different for gallstone-induced pancreatitis)

At Admission

G: Blood Glucose >11 mmol/L (>200 mg/dL) (with no history of hyperglycemia)

A: Age >55

L: Serum LDH >350 IU/L

A: AST >250 IU/L

W: WBC >16 × 10⁹/L (16,000/mm³)

During First 48 hours

C: Serum Calcium <2 mmol/L (<8 mEq/L)

H: Hematocrit drop >10%

O: Arterial PO₂ <60 mmHg

B: Base deficit >4 mmol/L (>4 mEq/L)

B: BUN rise >1.8 mmol/L (>5 mg/dL)

S: Estimated fluid Sequestration >6 L

- Difficult course if 2 criteria present
- High mortality if ≥3 criteria present

Prophylactic Antibiotics Cannot Reduce Infected Pancreatic Necrosis and Mortality in Acute Necrotizing Pancreatitis: Evidence from a Meta-analysis of Randomized Controlled Trials

Am J Gastroenterol 2008; 103:104-10

Purpose: To review the effectiveness of IV antibiotics on pancreatic necrosis.

Study Selection: Randomized controlled trials comparing antibiotics with placebo or no treatment.

Results: Seven trials (n= 467) were included.

Antibiotics were not statistically superior to controls in reduction of infected necrosis and mortality.

Conclusion: Prophylactic antibiotics cannot reduce infected pancreatic necrosis and mortality in patients with acute necrotizing pancreatitis.

Note: In practice the temptation to give antibiotics for pancreatitis is mainly in the setting of a sick patient with fever and suggestive pancreatic necrosis on CT scan. It is difficult to determine whether pancreatic necrosis has become infected without aspiration biopsy. See *Curr Gastroenterol Rep* 2009; 11:104-10.

Late Complications

- pseudocysts – follow if asymptomatic, drain if symptomatic or growing
 - drain: choice of endoscopic, percutaneous under radiological guidance, or surgical
- infected necrosis/abscesses – antibiotics + percutaneous drainage, endoscopic vs. surgical
- bleeding – (1) gastric varices if splenic vein thrombosis; (2) pseudoaneurysm of vessels in areas of necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged pancreas
- splenic and portal vein thrombosis – no effective therapy described, anticoagulation not proven, hazardous
- rare: diabetes, pancreatic duct damage

Chronic Pancreatitis

Definition

- irreversible damage to pancreas characterized by:
 - (1) pancreatic cell loss (from necrosis)
 - (2) inflammation
 - (3) fibrosis

Etiology/Pathophysiology

- alcohol (most common):
 - causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
 - changes composition of pancreatic juice (e.g. increases viscosity)
 - decreases pancreatic secretion of pancreatic stone protein (lithostathine) which normally solubilizes calcium salts
 - ♦ precipitation of calcium within pancreatic duct results in duct and gland destruction
 - toxic effect on acinar and duct cells – directly or via increasing free radicals
 - acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen (leading to fibrosis)
 - varying degrees of ductular dilatation, strictures, protein plugs, calcification
 - no satisfactory theory to explain why only a minority of alcoholics develop pancreatitis
- unusual causes
 - cystic fibrosis
 - severe protein-calorie malnutrition
 - hereditary
 - idiopathic
- never gallstones – cause acute pancreatitis only

Signs and Symptoms

- early stages:
 - recurrent attacks of severe abdominal pain (upper abdomen and back)
 - chronic painless pancreatitis: 10%
- late stages: occurs in 15% of patients
 - malabsorption syndrome when >90% of function is lost, steatorrhea
 - diabetes, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

Investigations

- laboratory:
 - increase in serum glucose
 - increase in serum ALP, less commonly bilirubin (jaundice)
 - serum amylase and lipase usually normal
- AXR: looking for pancreatic calcifications
- U/S: calcification, dilated pancreatic ducts, pseudocyst
- CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- 72-hour fecal fat test: exocrine function
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive
- fecal pancreatic enzyme measurement (elastase-1, chymotrypsin) available only in selected centres

Management

- most common problem is pain, difficult to control
- general management:
 - total abstinence from alcohol
 - enzyme replacement may help pain by resting pancreas via negative feedback
 - analgesics
 - celiac ganglion blocks
 - time – pain decreases with time as pancreas “burns out”

Symptoms of Chronic Pancreatitis

- Abdominal pain
- Diabetes
- Steatorrhea

Etiology = Almost Always Alcohol

Treatment

- Alcohol abstinence
- Pancreatic enzyme replacement
- Analgesics
- Pancreatic resection if ductular blockage

- endoscopy: sphincterotomy, stent if duct dilated, remove stones from pancreatic duct
- surgery: drain pancreatic duct (pancreaticojejunostomy) if duct dilated
 - resect pancreas if duct contracted
- steatorrhea:
 - pancreatic enzyme replacement
 - restrict fat, increase carbohydrate and protein (may also decrease pain)
 - neither endoscopy nor surgery can improve pancreatic function

Clinical Nutrition

Determination of Nutritional Status

- simple weight loss is most important parameter, expressed as body mass index (kg/m^2)

Investigations

- plasma proteins: albumin, pre-albumin (shorter half life than albumin), transferrin
 - decrease may indicate decreased nutritional status or disease state
- thyroid-binding globulin, retinol-binding protein (may be too sensitive)
- anthropometry (e.g. triceps skinfold thickness), grip strength less often used

Table 23. Areas of Absorption of Nutrients

	Fe	CHO	Proteins, Lipids Na, H ₂ O	Bile Acids	Vit B ₁₂
Duodenum	+++	+++	+++	+	
Jejunum		+	++	+	+
Ileum		+	++	+++	+++

Hypomagnesemia may be an initial sign of short bowel syndrome in patients who have undergone surgical bowel resection.

Most Common Indications for Artificial Nutrition Support include:

1. Preexisting nutritional deprivation
2. Anticipated or actual inadequate energy intake by mouth
3. Significant multiorgan system disease

Enteral Nutrition (EN)

Definition

- enteral nutrition (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
- choice of tubes: nasogastric, nasojejunal, percutaneous endoscopic gastrostomy, percutaneous endoscopic jejunostomy or tubes can be placed radiologically, surgically

Indications

- oral feeding inadequate or contraindicated

Feeds

- polymeric feeds contain whole protein, carbohydrate, fat as a liquid, with or without fibre
- elemental feeds contain protein as amino acids, carbohydrate as simple sugars, fat content low (therefore high osmolality)
- specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

Relative Contraindications

- non-functioning gut (e.g. intestinal obstruction, enteroenteral or enterocutaneous fistulae)
- uncontrolled diarrhea
- GI bleeding

Complications

- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnea, azotemia (from excess protein)

Enteral Nutrition Advantages over Parenteral Nutrition

- far fewer serious complications (especially sepsis)
- nutritional requirements for enterally administered nutrition better understood
- can supply gut-specific fuels such as glutamine and short chain fatty acids
- nutrients in the intestinal lumen prevent atrophy of the gut and pancreas
- prevents gallstones by stimulating gallbladder motility
- much less expensive

Parenteral Nutrition (PN)

Definition

- parenteral nutrition is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

Indications

- short term (<1 month)
 - whenever GI tract not functioning
 - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer
 - preoperative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/l or <2.8 g/dl), and only if given for ≥2 weeks
 - renal failure: PN shown to increase rate of recovery; no increase in survival
 - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
 - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)
 - some evidence for efficacy, but convincing data not available for:
 - radiation/chemotherapy-induced enteritis
 - AIDS with wasting diarrhea
 - severe acute pancreatitis
- long term (>1 month): can be given at home
 - severe untreatable small bowel disease (e.g. radiation enteritis, extensive Crohn's disease, high output fistulae)
 - following surgical resection of >70% of bowel (e.g. bowel infarction)
 - severe motility diseases (e.g. scleroderma affecting bowel)

Relative Contraindications

- functional GI tract for enteral nutrition
- active infection; at least until appropriate antibiotic coverage
- inadequate venous access; triple-lumen central venous lines usually prevent this problem
- unreliable patient or clinical setting

Complications of PN

- sepsis: most serious of the common complications
- mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
- metabolic: CHF, hyperglycemia, gallstones, cholestasis

Visualizing the GI Tract

- see also [Diagnostic Medical Imaging](#), D11

Esophagus, Stomach, Duodenum

- endoscopy (esophagogastroduodenoscopy) – best visualization of mucosa, allows for therapeutic intervention (band varices, cauterize/clip/inject bleeding ulcers)
 - consider barium swallow first if dysphagia, decreased level of consciousness (increases risk of aspiration), inability to cooperate (increases risk of pharyngeal trauma during intubation)
 - endotracheal intubation first if massive upper GI bleed, acidosis, unable to protect airway

Small Bowel

- most difficult to visualize if mucosal detail is needed
- most accurate is wireless endoscopy capsule (26 x 11 mm capsule is swallowed, transmits images to a computer; contraindicated if bowel obstruction)
- CT enterography (use enteroclysis if suspect obstruction) more accurate than small bowel swallow, but both have low sensitivity
- MRI enteroclysis increasingly available
- “double balloon” endoscopy (endoscope with balloons proximally and distally to propel endoscope into jejunum from mouth or into ileum from anus) may be most sensitive but currently available only in selected centres; technically demanding

Colon and Terminal Ileum

- colonoscopy, with biopsy if required; contraindicated in acute diverticulitis, severe colitis (increased risk of perforation)
- CT colonoscopy (“virtual colonoscopy”) more accurate in diagnosing diverticulosis, extrinsic pressure on colon (e.g. ovarian cancer compressing sigmoid colon), fistulae

Whenever possible, enteral nutrition is ALWAYS preferable over PN!

Pancreatic/Biliary Duct

- MRCP (magnetic resonance cholangiopancreatography = MRI of pancreas/bile duct) almost as sensitive as ERCP (endoscopic retrograde cholangiopancreatography) to determine if bile duct obstruction present, but less accurate in determining cause of obstruction (tumour, stone, stricture)
- use ERCP if endoscopic draining likely to be necessary, strong suspicion of stone or ampullary tumour
- MRCP reported to have lower sensitivity in sclerosing cholangitis than ERCP

Common Medications

Table 24. Common Drugs Prescribed in Gastroenterology

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Proton Pump Inhibitors (H ⁺ /K ⁺ -ATPase inhibitors)	omeprazole	Losec®/Prilosec®	20 mg OD	Inhibits gastric enzymes H ⁺ /K ⁺ -ATPase (proton pump)	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, reflux esophagitis, symptomatic GERD, dyspepsia, Zollinger-Ellison syndrome, eradication of <i>H. pylori</i> (combined with antibiotics)	Hypersensitivity to drug	Dizziness, headache, flatulence, abdo pain, nausea, rash, increased risk of osteoporotic fracture (secondary to impaired calcium absorption)
	lansoprazole	Prevacid®	Oral therapy: 15-30 mg OD (before breakfast) IV therapy: 30 mg OD	Same as above	Same as above	Same as above	Same as above
	pantoprazole	Pantoloc® Protonix®	40 mg OD for UGIB: 80 mg bolus then 8 mg/h infusion	Same as above	Same as above and UGIB	Same as above	Same as above
	rabeprazole	Pariet®/Aciphex®	40 mg OD	Same as above	Same as above	Same as above	Same as above
	esomeprazole	Nexium®	20-40 mg OD	Same as above	Same as above	Same as above	Same as above
Histamine H₂-receptor Antagonists	ranitidine	Zantac®	300 mg OD or 150 mg bid IV therapy: 50 mg q8h (but tachyphylaxis a problem)	Inhibits gastric histamine H ₂ -receptors	Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, ulcer prophylaxis, reflux esophagitis, symptomatic GERD, Zollinger-Ellison syndrome	Hypersensitivity to drug	Confusion, dizziness, headache, arrhythmias, constipation, nausea, agranulocytosis, pancytopenia, depression
	famotidine	Pepcid®	Oral therapy: duodenal/gastric ulcers: 40 mg qhs GERD: 20 mg bid IV therapy: 20 mg bid	Same as above	Same as above	Same as above	Same as above
Stool Softener	docusate sodium	Colace®	100-400 mg daily, divided in 1-4 doses	Promotes incorporation of water into stool	Relief of constipation	Presence of abdo pain, fever, nausea and vomiting	Throat irritation, abdo cramps, rashes
Laxative	lactulose	Lactulose/ Constulose®	Constipation: 15-30 ml OD to bid Encephalopathy: 15-30 ml bid to qid	Poorly absorbed in GI tract and is broken down by colonic bacteria into lactic acid into colon, increased osmotic colonic contents, increases stool volume	Chronic constipation, prevention and treatment of portal-systemic encephalopathy	Patients who require a low galactose diet	Flatulence, intestinal cramps, nausea, diarrhea if excessive dosage

Table 24. Common Drugs Prescribed in Gastroenterology (continued)

Class	Generic Drug Name	Trade Name	Dosing	Mechanism of Action	Indications	Contraindications	Side Effects
Peristaltic Stimulant	senna	Senokot®	Tablets: 1-4 qhs Syrup: 10-15 ml qhs	Senna glycosides are converted into aglycones in the colon and function as laxative agents by altering colonic water and electrolyte transport	Relief of constipation	Patients with acute abdomen	Abdo cramps, discolouration of breast milk, urine, feces, melanosis coli and atonic colon from prolonged use (controversial)
Antidiarrheal Agents	loperamide	Imodium®	Acute diarrhea: 4 mg initially, followed by 2 mg after each unformed stool	Acts as antidiarrheal via cholinergic, oncholingeric, opiate and nonopiate receptor-mediated mechanisms; decreases activity of myenteric plexus	Adjunctive therapy for acute non-specific diarrhea, chronic diarrhea associated with IBD and for reducing the volume of discharge for ileostomies, colostomies and other intestinal resections	Children <2 yrs, known hypersensitivity to drug, acute dysentery characterized by blood in stools and fever, acute ulcerative colitis or pseudomembranous colitis associated with broad-spectrum antibiotics	Abdo pain or discomfort, drowsiness or dizziness, tiredness, dry mouth, nausea and vomiting, hypersensitivity reaction
	diphenoxylate/atropine	Lomotil®	5 mg tid to qid	Inhibits GI propulsion via direct action on smooth muscle, resulting in a decrease in peristaltic action and increase in transit time	Adjunctive therapy for diarrhea, as above	Hypersensitivity to diphenoxylate or atropine, jaundice, pseudomembranous enterocolitis, diarrhea caused by enterotoxin producing bacteria	Dizziness, drowsiness, insomnia, headache, nausea, vomiting, cramps, allergic reaction
IBD Agents	mesalamine	Pentasa® Salofalk® Asacol® Mesasal®	CD: 1g tid/qid Active UC: 1g qid Maintenance UC: 1.6 g divided doses daily also as suppositories and enemas	5-ASA: Blocks arachidonic acid metabolism to prostaglandins and leukotrienes	IBD	Hypersensitivity to mesalamine salicylates	Abdo pain, constipation, arthralgia, headache
	sulfasalazine	Salazopyrin®	3-4 g/d in divided doses	Compound composed of 5-ASA bound to sulfapyridine, hydrolysis by intestinal bacteria releases 5-ASA, the active component	Colonic disease	Hypersensitivity to sulfasalazine, sulfa drugs, salicylates; intestinal or urinary obstruction, porphyria	Rash, loss of appetite, nausea, vomiting, headache, oligospermia (reversible)
	prednisone		20-40 mg OD for acute exacerbation	Anti-inflammatory	Mod-severe CD and UC		Complications of steroid therapy
Immuno-suppressive Agents	6-mercaptopurine (6-MP)	Purinethol®	CD: 1.5 mg/kg/day	Immunosuppressive	IBD: active inflammation and to maintain remission	Hypersensitivity to mercaptopurine, prior resistance to mercaptopurine or thioguanine, history of treatment with alkylating agents, hypersensitivity to azathioprine, pregnancy	Pancreatitis, bone marrow suppression, increased risk of cancer
	azathioprine	Azasan® Imuran®	IBD: 2-3 mg/kg/day	Same as above	Same as above	Same as above	Same as above
Immunomodulators	infliximab	Remicade®	5-10 mg/kg IV over 2 h	Antibody to tumour necrosis factor	Medically refractory CD	Heart failure, moderate to severe, doses >5 mg/kg	Reported cases of reactivated TB, PCP, lymphoma, other infections

Basic Anatomy Review

Common Acronyms

AAA – abdominal aortic aneurysm
 ABG – arterial blood gas
 ABI – ankle brachial index
 APR – abdominal perineal resection
 BRBPR – bright red blood per rectum
 CBD – common bile duct
 CVA – costovertebral angle
 CVP – central venous pressure
 DPL – diagnostic peritoneal lavage
 EBL – estimated blood loss
 OGD/EGD – esophagogastro-duodenoscopy
 ERCP – endoscopic retrograde cholangiopancreatography
 EUA – examination under anesthesia
 FAST – focused abdominal sonogram for trauma
 FNA – fine needle aspiration
 FOBT – fecal occult blood test
 I&D – incision and drainage
 LBO – large bowel obstruction
 LES – lower esophageal sphincter
 LGIB – lower GI bleed
 MAE – moving all extremities
 MEN – multiple endocrine neoplasia
 MIS – minimally invasive surgery
 MRCP – magnetic resonance cholangiopancreatography
 NGT – nasogastric tube
 POD – postoperative day
 SBO – small bowel obstruction
 SIADH – syndrome of inappropriate anti-diuretic hormone
 TEE – transesophageal echocardiogram
 TTE – transthoracic echocardiogram
 UGIB – upper GI bleed

Figure 1. Abdominal Incisions

Layers from Superficial to Deep

Figure 2. Continuity of the Abdominal Wall with Layers of the Scrotum and Spermatic Cord

- skin (epidermis, dermis, subcutaneous fat)
- superficial fascia
 - Camper's fascia (fatty) → Dartos
 - Scarpa's fascia (membranous) → Colle's superficial perineal fascia
- muscle (see Figure 2 and Figure 3)
 - external oblique → inguinal ligament → external spermatic fascia → fascia lata
 - internal oblique → cremasteric muscle/fascia
 - transversus abdominus → posterior inguinal wall
- transversalis fascia → internal spermatic fascia
- preperitoneal fat
- peritoneum → tunica vaginalis
- at midline
 - rectus abdominus muscle: in rectus sheath, divided by linea alba
- above arcuate line (semicircular line of Douglas), which is midway between symphysis pubis and umbilicus
 - anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
 - posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus muscle aponeurosis
- below arcuate line
 - anterior rectus sheath = aponeurosis of external, internal oblique, transversus muscles
 - posterior rectus sheath = transversalis fascia
- arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac); both arteries anastomose and lie behind the rectus muscle

Figure 3. Midline Cross-Section of Abdominal Wall

Figure 4. Blood Supply to the GI Tract

Venous Flow

- end point is the portal vein

Figure 5. Venous Drainage of the GI Tract

Organ	Arteries
Liver	Left and right hepatic (branches of hepatic proper)
Spleen	Splenic
Gallbladder	Cystic (Off right hepatic artery)
Stomach	1. Lesser curve-right and left gastric 2. Greater curve-right (off gastroduodenal) and left gastroepiploic (off splenic artery) (gastro-omental) 3. Fundus-short gastrics (off splenic)
Duodenum	1. Gastroduodenal 2. Pancreaticoduodenals (off superior mesenteric)
Pancreas	1. Splenic branches 2. Pancreaticoduodenals
Small intestine	1. Superior mesenteric branches – jejunal, ileal, ileocolic
Large intestine	1. Superior mesenteric branches – right colic, middle colic 2. Inferior mesenteric branches – left colic, sigmoid, rectal

Differential Diagnoses of Common Presentations

Acute Abdominal Pain

Table 1. Differential Diagnosis of Acute Abdominal Pain

RUQ	EPIGASTRIC	LUQ
Hepatobiliary Biliary colic Cholecystitis Cholangitis CBD obstruction (stone, tumour) Hepatitis Budd-Chiari Hepatic abscess/mass Right subphrenic abscess Gastrointestinal Pancreatitis Presentation of gastric, duodenal or pancreatic pathology Hepatic flexure pathology (CRC, subcostal incisional hernia) Genitourinary Nephrolithiasis Pyelonephritis Renal: mass, ischemia, trauma Cardiopulmonary RLL Pneumonia Effusion/Empyema CHF (causing hepatic congestion and R pleural effusion) MI Pericarditis Pleuritis Miscellaneous Herpes zoster Trauma Costochondritis	Cardiac Aortic dissection/ruptured AAA MI Pericarditis Gastrointestinal Gastritis GERD/Esoophagitis Peptic ulcer disease Pancreatitis Mallory-Weiss tear DIFFUSE Gastrointestinal Peritonitis Early appendicitis, perforated appendicitis Mesenteric ischemia Gastroenteritis/Colitis Constipation Bowel obstruction Pancreatitis Inflammatory bowel disease Irritable bowel syndrome Ogilvie's syndrome Cardiovascular/Hematological Aortic dissection/ruptured AAA Sickle cell crisis Genitourinary/Gynecological Perforated ectopic pregnancy PID Acute urinary retention Endocrinological Carcinoid syndrome Diabetic ketoacidosis Addisonian crisis Hypercalcemia Other Lead poisoning Tertiary syphilis	Pancreatic Pancreatitis (acute vs. chronic) Pancreatic pseudocyst Pancreatic tumours Gastrointestinal Gastritis Peptic ulcer disease Splenic flexure pathology (e.g. CRC, ischemia) Splenic Splenic infarct/abscess Splenomegaly Splenic rupture Splenic aneurysm Cardiopulmonary (see RUQ and Epigastric) Genitourinary (see RUQ) LLQ Gastrointestinal Diverticulitis Diverticulosis Colon/Sigmoid/Rectal Cancer Fecal impaction Proctitis (ulcerative colitis, infectious; i.e. gonococcus or chlamydia) Sigmoid volvulus Hernia See gynecological, urological, and extraperitoneal as per RLQ and suprapubic
RLQ Gastrointestinal Appendicitis Crohn's disease Tuberculosis of the ileocecal junction Cecal tumour Intussusception Mesenteric lymphadenitis (Yersinia) Cecal diverticulitis Cecal volvulus Hernia: amyands, femoral, inguinal obstruction (and resulting cecal distention) Gynecological See 'suprapubic' Genitourinary See 'suprapubic' Extraperitoneal Abdominal wall hematoma/abscess Psoas Abscess	SUPRAPUBIC Gastrointestinal (see RLQ/ LLQ) Acute appendicitis IBD Gynecological PID Ectopic pregnancy Endometriosis Threatened/Incomplete abortion Hydrosalpinx/Salpingitis Ovarian torsion Hemorrhagic fibroid Tubo-ovarian abscess Gynecological tumours Genitourinary Cystitis (infectious, hemorrhagic) Hydroureter/Urinary Colic Epididymitis Testicular torsion Acute urinary retention Extraperitoneal Rectus sheath hematoma	

In all patients presenting with an acute abdomen, order the following:

1. Amylase/lipase
2. Urinalysis
3. Beta-hCG (in women)
4. Consider CXR + troponins

This will help rule out "non-GI surgical" causes!

Pancreatitis can look like a surgical abdomen, but is rarely an indication for laparotomy.

Referred Pain

Biliary colic: to right shoulder or scapula
 Renal colic: to groin
 Appendicitis: periumbilical to right lower quadrant (RLQ)
 Pancreatitis: to back
 Ruptured aortic aneurysm: to back or flank
 Perforated ulcer: to RLQ (right paracolic gutter)
 Hip pain: to groin

Abdominal Mass

Table 2. Differential Diagnosis of Abdominal Mass

Right Upper Quadrant (RUQ)	Upper Midline	Left Upper Quadrant (LUQ)
Gallbladder – cholecystitis, cholangiocarcinoma, cholelithiasis	Pancreas – pancreatic adenocarcinoma, IPMT, other pancreatic cancer, pseudocyst	Spleen – splenomegaly, tumour, abscess, subcapsular splenic hemorrhage, can also present as RLQ mass if extreme splenomegaly
Biliary tract – Klatskin tumour	Abdominal aorta – AAA (pulsatile)	Stomach – tumour
Liver – hepatomegaly, hepatitis, abscess, tumour (hepatocellular carcinoma, metastatic tumour, etc.)	Gastric tumour (adenocarcinoma, gastrointestinal stromal tumour, carcinoid tumour), MALT lymphoma	
Right Lower Quadrant (RLQ)	Lower Midline	Left Lower Quadrant (LLQ)
Intestine – stool, tumour (CRC), mesenteric adenitis, appendicitis, appendicular phlegmon or other abscess, typhlitis, intussusception, Crohn's inflammation	Uterus – pregnancy, leiomyoma (fibroid), uterine cancer, pyometria, hematometria	Intestine – stool, tumour, abscess (see RLQ)
Ovary – ectopic pregnancy, cyst (physiological vs. pathological), tumour (serous, mucinous, struma ovarii, germ cell, krukberg)	GU – bladder distention, tumour	Ovary – ectopic pregnancy, cyst, tumour (see RLQ)
Fallopian tube – ectopic pregnancy, tubo-ovarian abscess, hydrosalpinx, tumour		Fallopian tube – ectopic pregnancy, tubo-ovarian abscess, hydrosalpinx, tumour

Indications for Urgent Operation

IHOP
Ischemia
Hemorrhage
Obstruction
Perforation

GI Bleeding

- see Gastroenterology, G26-29

Indications for Surgery

- failure of medical management
- prolonged bleeding, significant blood loss (requiring >6 units of pRBCs in a short period of time), high rate of bleeding, hypotension
- bleeding that persists despite endoscopic and angiographic therapeutic maneuvers

Surgical Management of GI Bleeding

- upper GI bleeding:
 - bleeding from a source proximal to the ligament of Treitz
 - often presents with hematemesis and melena unless very brisk (then can present with BRBPR, hypotension, tachycardia)
 - initial management with endoscopy; if fails, then consider surgery
- lower GI bleeding:
 - bleeding from a source distal to the ligament of Treitz
 - often presents with BRBPR unless proximal to transverse colon
 - ♦ may occasionally present with melena
 - initial management with colonoscopy to detect and potentially stop source of bleeding
 - angiography, RBC scan to determine source as indicated
 - ♦ surgical intervention if no source found

Table 3. Differential Diagnosis of GI Bleeding

Anatomical Source	Etiology	
Hematological	Excess anticoagulation (coumadin, heparin, etc.)	DIC Congenital bleeding disorders
Nose	Epistaxis	
Esophagus	Esophageal varices Mallory-Weiss tear Esophagitis	Aorto-esophageal fistula (generally post endovascular aortic repair)* Esophageal cancer
Stomach	Gastritis Gastric varices Dieulafoy lesion	Gastric ulcer Gastric cancer*
Duodenum	Duodenal ulcer Perforated duodenal ulcer*	Duodenal cancer*
Jejunum	Tumours*	
Ileum and Ileocecal Junction	Meckel's diverticulum (rare surgical management) Small bowel obstruction	Crohn's disease* Tuberculosis of ileocecal junction

Table 3. Differential Diagnosis of GI Bleeding (continued)

Anatomical Source	Etiology	
Large Intestine	Colorectal cancer* Mesenteric thrombosis/ischemic bowel* Ulcerative colitis* (subtotal colectomy if failure of medical management) Angiodysplasia	Crohn's disease (less frequently presents with bleeding)* Pancolitis (infectious, chemotherapy or radiation induced) Bleeding post-gastrointestinal anastomosis
Sigmoid	Diverticulosis* Sigmoid cancer* Bleeding post-polypectomy	Polyps* (surgical management if not amenable to colonoscopic polypectomy) Inflammatory bowel disease (IBD)
Rectum and Anus	Hemorrhoids Fissures Rectal cancer* Anal varices	Polyps* (surgical management if not amenable to polypectomy) Crohn's or ulcerative colitis* Solitary rectal ulcer syndrome

*Managed surgically in most cases

Jaundice

- see Gastroenterology, G44

Differential Diagnosis

- **pre-hepatic**
 - pathology occurring prior to the liver
 - ♦ hemolysis
 - ♦ Gilbert's disease, Crigler-Najjar disease
- **hepatic**
 - pathology occurring at the level of the liver
 - ♦ viral hepatitis
 - ♦ alcoholic hepatitis, cirrhosis
 - ♦ drug-induced hepatitis – acetaminophen, erythromycin, isoniazid, valproic acid, phenytoin, oral contraceptive pill
 - ♦ Dubin-Johnson syndrome
- **post-hepatic:**
 - pathology is located after the conjugation of bilirubin in the liver
 - ♦ choledocholithiasis, cholangitis, sclerosing cholangitis, choledochal cyst
 - ♦ benign biliary stricture
 - ♦ carcinoma – bile duct, head of pancreas, ampulla of Vater, duodenum

Bilirubin Levels

	Prehepatic	Intrahepatic	Posthepatic
Serum bilirubin			
Indirect	↑	↑	N
Direct	N	↑	↑
Urine			
Urobilinogen	↑	↑	Absent
Bilirubin	–	+	+
Fecal			
Urobilinogen	↑	↑	Absent

Approach to the Critically Ill Surgical/Trauma Patient ABC, I'M FINE ABC

- I** – IV: 2 large bore IV's with NS, wide open
- M** – Monitors: O₂ sat, ECG, BP
- F** – Foley catheter to measure urine output
- I** – Investigations: bloodwork
- N** – NG tube if indicated
- E** – "Ex" rays (abdomen 3 views, CXR), other imaging

DRUGS – 6 A's

Analgesia
Anti-emetic
Anti-coagulation
Antibiotics
Anxiolytics
All other patient meds

Preoperative Preparations

Considerations

- informed consent (see Ethical, Legal and Organizational Aspects of Medicine, ELOAM8)
- consults – anesthesia, medicine, cardiology as indicated
- NPO after midnight, AAT (activity as tolerated), VSR (vital signs routine)
- IV – balanced crystalloid at maintenance rate (4:2:1 rule → roughly 100-125 cc/hr): normal saline or Ringer's lactate; bolus to catch up on estimated losses from bowel prep
- patient's regular meds including prednisone – consider pre-op stress dose if prednisone used in past year
- prophylactic antibiotics (within 1 hour prior to incision): usually cefazolin (Ancef®) ± metronidazole (Flagyl®)
- bowel prep: cleans out bowel and decreases bacterial population
 - oral cathartic (e.g. fleet Phosphosoda®) starting previous day
 - used for left-sided or rectal resections (routine use is controversial and probably unnecessary)
- consider DVT prophylaxis for all inpatient surgery (heparin)
- hold ASA x 1 week preop
- smoking cessation x 6 weeks preop can significantly decrease postop complications

Investigations

- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, BUN, creatinine
- INR/PT, PTT with history of bleeding disorder
- ABGs if predisposed to respiratory insufficiency
- CXR (PA and lateral) if >50 years old or previously abnormal within past 6 months
- ECG if >50 years old or as indicated by history

Drains

- nasogastric (NG) tube:
 - indications: gastric decompression, analysis of gastric contents, irrigation/dilution of gastric contents, feeding (only if necessary due to risk of aspiration → naso-jejunal tube preferable)
 - contraindications: suspected basal skull fracture, obstruction of nasal passages due to trauma
- Foley catheter:
 - indications: to accurately monitor urine output, decompression of bladder, relieve obstruction
 - contraindications: suspected urethral injury, difficult insertion of catheter

Surgical Complications

Postoperative Fever

- fever does not necessarily imply infection
- timing of fever may help identify cause
- POD #0-2:
 - atelectasis (most common cause of fever on POD #1)
 - early wound infection (especially *Clostridium*, Group A *Streptococcus* – feel for crepitus and look for “dishwater” drainage)
 - aspiration pneumonitis
 - other: Addisonian crisis, thyroid storm, transfusion reaction
- POD #3:
 - infections more likely
 - UTI, wound infection, IV site infection, septic thrombophlebitis
- POD #5+:
 - leakage at bowel anastomosis (tachycardia, hypotension, oliguria, abdominal pain)
 - intra-abdominal abscess (usually POD #5-10)
 - DVT/PE (can be anytime post-op, most commonly POD #7-10)
 - drug fever (POD #6-10)
- other: cholecystitis, peri-rectal abscess, URTI, infected seroma/biloma/hematoma, parotitis, *C. difficile* colitis, endocarditis

“5 W’s” of Post-Op Fever

Wind (pulmonary)

Water (urine-UTI)

Wound

Walk (DVT/PE)

Wonder drugs (drug fever)

Correlate with time spent in post-op period.

Treatment

- treat primary cause
- antipyrexia (e.g. acetaminophen)

Wound Complications

WOUND CARE

- epithelialization of wound occurs 48 hours after closure
- dressings applied in the operating room can be removed POD #2-4
- leave uncovered if wound is dry
- remove dressings if wet, signs of infection (fever, tachycardia, pain)
- examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
- skin sutures and staples can be removed POD #5:
 - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use) removed POD #14, earlier if signs of infection
- can bathe POD #2-3
- negative pressure dressings consist of gel foam and suction, promote granulation
 - ideal for large (grafted sites) or nonhealing wounds (irradiated skin, ulcer)

DRAINS

- placed intra-operatively to prevent fluid accumulation (blood, pus, serum, bile, urine)
- potential route of infection, bring out through separate incision (vs. operative wound) to decrease risk of wound infection
- types of drains
 - open (Penrose), higher risk of infection
 - closed (Jackson-Pratt, Blake) connected to suction
 - sump (Davol) suction with airflow system to prevent obstruction
- monitor drain outputs daily
- drains should be removed once drainage is minimal (usually less than 30-50 cc/24hr)

WOUND INFECTION

Etiology

- S. aureus*, *E. coli*, *Enterococcus*, *Streptococcus* spp., *Clostridium* spp.

Risk Factors

- type of procedure:
 - clean (elective, not emergent, not traumatic, no acute inflammation, resp/GI/biliary/GU tracts not entered): <1.5%
 - clean-contaminated (elective entering of resp/GI/biliary/GU tracts): <3%
 - contaminated (nonpurulent inflammation, gross spillage from GI, entry into biliary or GU tracts with infected bile/urine, penetrating trauma <4 hrs old): 5%

Antimicrobial Prophylaxis for Surgery:
An Advisory Statement from the National
Surgical Infection Prevention Project
Clin Infect Dis 2004; 38:1706

Level IV Evidence (Consensus)

General Recommendations from Consensus Panel:

The first antimicrobial dose should be administered via infusion within 60 minutes of the surgical incision and prophylactic antimicrobials should be discontinued within 24 hours postoperatively.

The initial dose should be based on the patient's body weight, adjusted dosing weight, or BMI. If the surgical procedure is still in progress 2 half-lives after the initial dose, another dose should be administered intraoperatively.

General Abdominal Colorectal surgery:

For parenteral antimicrobial prophylaxis, use cefoxitin OR cefotetan OR cefazolin plus metronidazole.

If the patient has a β -lactam allergy, use clindamycin combined with either gentamicin, ciprofloxacin, or aztreonam, OR metronidazole combined with either gentamicin or ciprofloxacin.

Chlorhexidine-Alcohol versus Povidone-Iodine for Surgical-Site Antisepsis

Darouiche RO et al. *NEJM* 2010; 362:18-26

Purpose: To determine whether preoperative skin cleansing with chlorhexidine-alcohol is more protective against infection than povidone-iodine.

Methods: Randomized trial of adults undergoing clean-contaminated surgery in six hospitals to preoperative skin preparation with either chlorhexidine-alcohol scrub or povidone-iodine scrub and paint.

Main outcomes: Any surgical-site infection within 30 days after surgery

Results: A total of 849 subjects (409 in the chlorhexidine-alcohol group and 440 in the povidone-iodine group) qualified for the intention-to-treat analysis. The overall rate of surgical-site infection was significantly lower in the chlorhexidine-alcohol group than in the povidone-iodine group (9.5% vs. 16.1%; $P=0.004$; relative risk, 0.59; 95% confidence interval, 0.41 to 0.85). Chlorhexidine-alcohol was significantly more protective than povidone-iodine against both superficial incisional infections (4.2% vs. 8.6%, $P=0.008$) and deep incisional infections (1% vs. 3%, $P=0.05$) but not against organ-space infections (4.4% vs. 4.5%). Similar results were observed in the per-protocol analysis of the 813 patients who remained in the study during the 30-day follow-up period. Adverse events were similar in the two study groups.

Conclusions: Preoperative cleansing of the patient's skin with chlorhexidine-alcohol is superior to cleansing with povidone-iodine for preventing surgical-site infection after clean-contaminated surgery.

- dirty (purulent inflammation, pre-op perforation of resp/GI/biliary/GU tracts, penetrating trauma >4 hrs old): 33%
- increased risk with procedures >2 hrs long, use of drains
- patient characteristics:
 - age, DM, steroids, immunosuppression, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, chemotherapy
- other factors:
 - prolonged preoperative hospitalization, reduced blood flow, break in sterile technique, multiple antibiotics, hematoma, seroma, foreign bodies (drains, sutures, grafts)

Clinical Presentation

- typically fever POD #3-6 (*Streptococcus* and *Clostridium* can present in 24 hrs)
- pain, blanchable wound erythema, induration, frank pus or purulosanguinous discharge, warmth
- complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, hernia

Prophylaxis

- pre-op antibiotics for all surgeries [cefazolin (Ancef®)/metronidazole (Flagyl®)]:
 - within 1 hour preincision; can re-dose with Ancef® after 4 hrs in the OR
- post-op antibiotics for contaminated and dirty surgeries:
 - no evidence supporting more than 24 hrs of post-op antimicrobial prophylaxis for any case
 - generally no need for post-op antibiotics unless intra-abdominal infection
- normothermia (maintain patient temperature >36°C during OR)
- hyperoxygenation (consider FiO₂ >80 in OR)

Treatment

- re-open affected part of incision, culture wound, pack, heal by secondary intention
- antibiotics only if cellulitis or immunodeficiency
- debride necrotic and non-viable tissue intraoperatively

WOUND HEMORRHAGE/HEMATOMA

- secondary to inadequate surgical control of hemostasis

Risk Factors

- anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial hypertension, severe cough

Clinical Features

- pain, swelling, discolouration of wound edges, leakage
- rapidly expanding neck hematoma can compromise airway and is a surgical emergency

Treatment

- pressure dressing
- if significant bleeding, may need to re-operate to find source

SEROMA

- fluid collection other than pus or blood
- secondary to transection of lymph vessels
- delays healing

Treatment

- pressure dressing \pm needle drainage
- if significant may need to re-operate

WOUND DEHISCENCE

- disruption of fascial layer, abdominal contents contained by skin only

Clinical Features

- typically POD #1-3, most common presenting sign is serosanguinous drainage from wound, \pm evisceration (disruption of all abdominal layers and extrusion of abdominal contents – mortality of 15%)
- palpation of wound edge: should normally feel a "healing ridge" from abdominal wall closure (raised area of tissue under incision)

Risk Factors

- local: technical failure of closure, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation
- systemic: smoking, malnutrition (hypoalbuminemia, vitamin C), connective tissue diseases, immunosuppression (disease, steroids, chemotherapy), other (age, DM, sepsis, uremia)

Treatment

- may consider conservative management
- operative closure, evisceration is a surgical emergency

Urinary and Renal Complications

URINARY RETENTION

- may occur after any operation with general anesthesia or spinal anesthesia
- more likely in older males with history of benign prostatic hyperplasia (BPH), patients on anticholinergics

Clinical Presentation

- abdominal discomfort, palpable bladder, overflow incontinence

Treatment

- Foley catheter to rest bladder, then trial of void

OLIGURIA/ANURIA (see also [Nephrology](#), NP20)**Etiology**

- pre-renal vs. renal vs. post-renal:
 - most common post-op cause is pre-renal ± ischemic ATN
 - ♦ external fluid loss: hemorrhage, dehydration, diarrhea
 - ♦ internal fluid loss: third-spacing due to bowel obstruction, pancreatitis, post-op

Clinical Presentation

- urine output <0.5 cc/kg/hr, increasing Cr, increasing BUN

Treatment

- according to underlying cause; fluid deficit is treated with crystalloid, [normal saline (NS) or Ringer's lactate (RL)]

Postoperative Dyspnea

- see *Respiratory Complications*, GS9 and *Cardiac Complications*, GS11
- respiratory: atelectasis, pneumonia, pulmonary embolus (PE), acute respiratory distress syndrome (ARDS), asthma, pleural effusion
- cardiac: MI, arrhythmia, CHF
- pain

Respiratory Complications

ATELECTASIS

- comprises 90% of post-op pulmonary complications

Clinical Features

- low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, tachypnea

Risk Factors

- COPD, smoking, obesity, elderly persons
- upper abdominal/thoracic surgery, oversedation, significant post-op pain, poor inspiratory effort

Treatment

- pre-operative prophylaxis:
 - smoking cessation (most beneficial if >6 weeks pre-op)
- postoperative prophylaxis:
 - minimize use of respiratory depressant drugs
 - good pain control
 - incentive spirometry, deep breathing and coughing, chest physiotherapy, postural changes
 - early ambulation

PNEUMONIA/PNEUMONITIS

- may be secondary to aspiration of gastric contents during anesthetic induction or extubation, causing a chemical pneumonitis

Risk Factors

- aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NG tube, pregnancy, seizure disorder
- non-aspiration: atelectasis, immobility, pre-existing respiratory disease

Clinical Features

- productive cough, fever
- tachycardia, cyanosis, respiratory failure, decreased LOC
- CXR: pneumonic infiltrate

Treatment

- aspiration prophylaxis: pre-op NPO/NG tube, rapid sequence anesthetic induction
- immediate removal of debris and fluid from airway
- consider endotracheal intubation and flexible bronchoscopic aspiration
- IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. cefotaxime, metronidazole)

PULMONARY EMBOLUS (see Respirology, R18)**Clinical Features**

- unilateral leg swelling and pain (DVT as a source of PE), sudden onset SOB, tachycardia, fever (POD #7-10)

Treatment

- IV heparin, long term warfarin (INR = 2-3) for 3 months
- Greenfield (IVC) filter if contraindications to anticoagulation
- prophylaxis: subcutaneous heparin (5000 units bid) or LMW heparin, compression stockings (TED stockings)

PULMONARY EDEMA**Etiology**

- cardiogenic vs. noncardiogenic
- circulatory overload: excess volume replacement, LV failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, alveolar injury due to toxins (e.g. ARDS)
 - more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anaesthesia

Clinical Features

- SOB, crackles at lung bases, CXR abnormal

Treatment (LMNOP)

- Lasix
- Morphine (decreases symptoms of dyspnea, venodilator and afterload reduction)
- Nitrates (venodilator)
- Oxygen + non-invasive ventilation
- Position (sit patient up)

RESPIRATORY FAILURE**Clinical Features**

- dyspnea, cyanosis, evidence of obstructive lung disease
- earliest manifestations – tachypnea and hypoxemia (RR >25, pO₂ <60)
- pulmonary edema, unexplained decrease in SaO₂

Treatment

- ABCs, O₂, ± intubation
- bronchodilators, diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO₂ >60, consider ARDS

Cardiac Complications

- abnormal ECGs common in post-op period (compare to pre-op ECG)
- common arrhythmias: supraventricular tachycardia (SVT), atrial fibrillation (secondary to fluid overload, PE, MI)

MYOCARDIAL INFARCTION (MI)

- see Cardiology and Cardiovascular Surgery, C25
- surgery increases risk of MI
- incidence:
 - 0.5% in previously asymptomatic men >50 years old
 - 40-fold increase in men >50 years old with previous MI

Risk Factors

- pre-op hypertension, CHF
- previous MI (highest risk ≤6 months, but risk never returns to baseline)
- increased age
- intra-operative hypotension
- operations >3 hrs
- angina

Clinical Features

- majority of cases on day of operation or POD #1-4
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, hypotension

Intra-abdominal Abscess

Definition

- collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

Etiology

- usually polymicrobial: Gram-negative bacteria, anaerobes
- consider Gram-positives if coexistent cellulitis

Risk Factors

- emergency OR
- post-op contaminated OR
- GI surgery with anastomoses
- poor healing risk factors (DM, poor nutrition, etc.)
- may occur POD #3 after laparotomy when fluid re-distribution occurs

Clinical Features

- persistent spiking fever, dull pain, weight loss
- mass difficult to palpate
- peritoneal signs if abscess perforation and secondary peritonitis
- leukocytosis or leukopenia (immunocompromised, elderly)
- co-existing effusion (pleural effusion with subphrenic abscess)
- common sites: pelvis, Morrison's pouch (space between duodenum and liver), subphrenic, paracolic gutters, lesser sac, peri-appendiceal, post-surgical anastomosis, diverticular, psoas

Investigations

- CBC, blood cultures x 2
- CT ± water-soluble contrast
- DRE (pelvic abscess)

Treatment

- IR percutaneous drainage
- debridement of infected soft tissue around infection
- antibiotics to cover aerobes and anaerobes (ampicillin/gentamicin/metronidazole or ciprofloxacin/metronidazole or clindamycin/gentamicin or cefotetan)

Paralytic Ileus

- see *Bowel Obstruction*, GS23

Delirium

- see Psychiatry, PS17 and Neurology, N10

Thoracic Surgery

Esophagus

Figure 6. Types of Hiatus Hernia – Sliding (left) and Paraesophageal (right)

SLIDING HIATUS HERNIA (Type I) (see Figure 6)

- herniation of both the stomach and the gastroesophageal (GE) junction into thorax
- 90% of esophageal hernias

Risk Factors

- age
- increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, heavy lifting, straining with constipation)
- smoking

Clinical Features

- majority are asymptomatic
- larger hernias frequently associated with GERD due to disruption of competence of GE junction and prevention of acid clearance once reflux has occurred

Complications

- most common complication is GERD
- other complications are rare and are related to reflux:
 - esophagitis (dysphagia, heartburn)
 - consequences of esophagitis (peptic stricture, Barrett's esophagus, esophageal carcinoma)
 - extra-esophageal complications (aspiration pneumonia, asthma, cough, laryngitis)

Investigations

- barium swallow, endoscopy, or esophageal manometry (technique for measuring LES pressure) detect larger hernias
- 24-hour esophageal pH monitoring to quantify reflux
- gastroscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett's, and cancer
- CXR: globular shadow with air-fluid level visible over cardiac shadow

Treatment

- treat symptoms of GERD:
 - lifestyle modification:
 - ♦ stop smoking, weight loss, elevate head of bed, no meals <3 hrs prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint and fat
 - medical:
 - ♦ antacid, H₂-antagonist, proton pump inhibitor, adjuvant prokinetic agent
 - surgical (<15%):
 - ♦ if severe complications or if refractory to medical management
 - ♦ Nissen fundoplication (usually laparoscopic)
 - fundus of stomach is wrapped around the lower esophagus and sutured in place
 - 90% success rate

Differential Diagnosis of Hiatus Hernia

GI Causes	Non-GI Causes
<ul style="list-style-type: none"> • Cholelithiasis • Diverticulitis • Peptic ulcer • Achalasia • Pancreatitis • GERD • Gastritis 	<ul style="list-style-type: none"> • MI • Angina • Pericarditis

PARAESOPHAGEAL HIATUS HERNIA (Type II) (see Figure 6)

- herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction
- least common esophageal hernia (<10%)

Clinical Features

- usually asymptomatic due to normal GE junction
- pressure sensation in lower chest, dysphagia

Complications

- hemorrhage, incarceration, strangulation, obstruction, gastric stasis ulcer

Treatment

- surgery to prevent severe complications:
 - reduce hernia and excise hernia sac, repair defect at hiatus, and Nissen fundoplication
 - may consider suturing stomach to anterior abdominal wall (gastropexy)
 - in very elderly patients at high surgical risk consider PEG (percutaneous endoscopic gastrostomy)

MIXED HIATUS HERNIA (Type III)

- combination of Types I and II

TYPE IV HERNIA

- herniation of other abdominal organs into thorax: colon, spleen, small bowel

ESOPHAGEAL PERFORATION**Etiology**

- iatrogenic (most common):
 - endoscopic, dilation, biopsy, intubation, operative, NG tube placement
- barogenic:
 - repeated, forceful vomiting (Boerhaave's syndrome)
 - trauma
 - other: convulsions, defecation, labour (rare)
- ingestion injury:
 - foreign body, corrosive substance
- carcinoma

Clinical Features

- neck or chest pain
- fever, tachycardia, hypotension, dyspnea, respiratory compromise
- subcutaneous emphysema, pneumothorax, hematemesis

Investigations

- CXR: pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air
- CT chest: widened mediastinum, pneumomediastinum
- contrast swallow (water-soluble then thin barium): contrast extravasation

Treatment

- supportive if rupture is contained:
 - NPO, vigorous fluid resuscitation, broad-spectrum antibiotics
- surgical:
 - <24 hrs
 - ♦ primary closure of a healthy esophagus or resection of diseased esophagus
 - >24 hrs or non-viable wound edges
 - ♦ diversion and exclusion followed by delayed reconstruction (i.e. esophagostomy proximally, close esophagus distally, gastrostomy/jejunostomy for decompression/feeding)

Complications

- sepsis, abscess, fistula, empyema, mediastinitis, death
- post-op esophageal leak
- mortality 10-50% dependant on timing of diagnosis

Boerhaave's – transmural esophageal perforation

Mallory-Weiss tear – non-transmural esophageal tear (partial thickness tear)

Both are associated with forceful emesis.

ESOPHAGEAL CARCINOMA

Epidemiology

- male:female = 3:1
- onset 50-60 years of age
- upper (20-33%), middle (33%), lower (33-50%)
- squamous cell carcinoma (SCC) and adenocarcinoma occur with equal frequency, with adenocarcinoma becoming more common

Risk Factors

- geographic variation in incidence
- squamous cell carcinoma (SCC):
 - **4 S's:** Smoking, Spirits (alcohol), Seeds (Betel nut), Scalding (hot liquids)
 - underlying esophageal disease such as strictures, diverticula, achalasia
- adenocarcinoma:
 - Barrett's esophagus (most important), smoking, obesity (increased reflux), GERD

Clinical Features

- frequently asymptomatic – late presentation
- progressive dysphagia (mechanical) – first solids then liquids
- odynophagia then constant pain
- constitutional symptoms
- regurgitation and aspiration (aspiration pneumonia)
- hematemesis, anemia
- tracheoesophageal or bronchoesophageal fistula
- direct, hematogenous or lymphatic spread:
 - trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aortic, liver, lung, bone, celiac and mediastinal nodes
- weight loss

Investigations

- barium swallow:
 - shows narrowing – suggestive but not diagnostic
- esophagoscopy:
 - biopsy/tissue diagnosis
 - determine extent and resectability of tumour
- CT chest/abdomen:
 - visualize local disease
 - staging workup (adrenal, liver, lung, bone metastases)
- endoscopic ultrasound (EUS):
 - visualize local disease
 - regional nodal involvement (most accurate way to stage the cancer)
- bronchoscopy:
 - rule out airway invasion in tumours of the upper and mid esophagus

Treatment

- if inoperable or unresectable (locally invasive disease or distant mets):
 - multimodal therapy:
 - ♦ concurrent external beam radiation and chemotherapy (cisplatin and 5-FU)
 - ♦ possibility of curative esophagectomy after chemoradiation if disease responds well
 - if unable to tolerate multimodal therapy or if highly advanced disease, consider palliative resection, brachytherapy, or endoscopic dilation/stenting/laser ablation for palliation
- if operable:
 - esophagectomy (transthoracic or trans-hiatal approach) and lymphadenectomy
 - ♦ anastomosis in chest or neck
 - ♦ stomach most often used for reconstruction; may also use colon
 - neoadjuvant chemotherapy and radiation are controversial
 - adjuvant chemotherapy ± radiation usually recommended for post-op node-positive disease

Prognosis

- 5-8% operative death rate
- prognosis usually poor because presentation is usually at advanced stage

OTHER DISORDERS

- esophageal varices (see [Gastroenterology, G27](#))
- Mallory-Weiss tear (see [Gastroenterology, G28](#))

Chest Wall

CONGENITAL ABNORMALITIES

- pectus excavatum, pectus carinatum, sternal fissures
- surgery for: cosmesis, psychosocial factors, respiratory or cardiovascular insufficiency

THORACIC OUTLET SYNDROME

- impingement of subclavian vessels and brachial plexus nerve trunk

Etiology

- congenital – cervical rib
- trauma
- degenerative – osteoporosis, arthritis

Clinical Features

- neurogenic – ulnar and median nerve motor and sensory function
- arterial – fatigue, weakness, coldness, ischemic pain, paresthesia
- venous – edema, venous distention, collateral formation, cyanosis

Treatment

- conservative (50 to 90%)
 - physiotherapy, posture and behaviour modification
- surgical – if conservative treatment fails, removal of first or cervical rib (if applicable)

TUMOURS

- benign: fibrous dysplasia, eosinophilic granuloma, osteochondroma
- malignant: fibrosarcoma, chondrosarcoma, osteogenic sarcoma, Ewing's sarcoma, myeloma

Figure 7. Typical Thoracic Surgery Incisions

Pleura, Lung, and Mediastinum

- see Respirology, R21

TUBE THORACOSTOMY

Indications

- to drain abnormal large-volume air or fluid collections in the pleural space
 - hemothorax, chylothorax, empyema
 - pneumothorax, if:
 - ♦ large or progressive
 - ♦ patient is on mechanical ventilation
 - ♦ bronchopleural fistula
 - ♦ tension pneumothorax
- to facilitate pleurodesis:
 - i.e. obliteration of the pleural space by instilling talc or doxycycline to cause fibrosis and adherence of parietal and visceral pleura
 - indicated for recurrent pleural effusions (often malignant)
- for long-term drainage of malignant effusions

Procedure

- tube size – varies according to indication; larger tube for more viscous drainage
- insertion site – typically 4th or 5th intercostal space in anterior axillary or mid-axillary line
- technique:
 - local anaesthetic
 - ~2 cm skin incision
 - Kelly clamp for blunt dissection to the pleural space, taking care to pass over the top of the rib to avoid neurovascular bundle
 - tube is inserted and sutured in place
 - tube is attached to a pleural drainage system (suction/underwater seal, usually -20 mmH₂O)
 - post-insertion CXR to ensure proper tube placement (posterior apex of lung)
- removal:
 - when drainage <100-200 cc/day, no air leak, and lung is fully expanded
 - consider clamping tube for 4-6 hrs then obtaining CXR to ensure lung remains expanded
 - brisk removal after patient expires and holds breath

Complications

- overall complications are rare (1-3%)
- malposition (most common complication), especially by inexperienced operators:
 - tubes may dissect along the external chest wall, or may be placed below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma
- risk of re-expansion pulmonary edema when large volumes of air or fluid are drawn off quickly (>1.0 to 1.5 L)

Stomach and Duodenum

Peptic Ulcer Disease

GASTRIC ULCERS

- see Gastroenterology, G11, G27

Surgical Treatment

- increasingly rare due to *H. pylori* eradication and medical treatment

Indications for Surgery

- unresponsive to medical treatment (intractability):
 - always operate if fails to heal completely, even if biopsy negative – could be primary gastric lymphoma or adenocarcinoma
- dysplasia or carcinoma:
 - always biopsy ulcer for malignancy
- hemorrhage – 3x greater risk of bleeding compared to duodenal ulcers
- complications: obstruction, perforation, bleeding

Procedures

- distal gastrectomy with ulcer excision – Billroth I or Billroth II (see Figure 8)
- vagotomy and pyloroplasty only if acid hypersecretion – rare
- wedge resection if possible or biopsy with primary repair

DUODENAL ULCERS

- see Gastroenterology, G12
- most within 2 cm of pylorus (duodenal bulb)

Complications

- perforated ulcer (typically on anterior surface)
 - clinical features:
 - ♦ sudden onset of pain (possibly in RLQ due to track down right paracolic gutter)
 - ♦ acute abdomen – rigid, diffuse guarding
 - ♦ ileus
 - ♦ initial chemical peritonitis followed by bacterial peritonitis
 - investigations:
 - ♦ CXR – free air under diaphragm (70% of patients)
 - treatment:
 - ♦ oversew ulcer (plication) and omental (Graham) patch – most common treatment
- posterior penetration:
 - into pancreas → elevated amylase/lipase
 - constant mid-epigastric pain burrowing into back, unrelated to meals
- hemorrhage (typically on posterior surface):
 - gastroduodenal artery involvement
 - treatment:
 - ♦ resuscitation initially with crystalloids; blood transfusion if necessary
 - ♦ diagnostic and/or therapeutic endoscopy (laser, cautery or injection); if recurs, may have 2nd scope
 - ♦ surgery if severe or recurrent bleeding, hemodynamically unstable, or failure of endoscopy
 - oversewing of ulcer, pyloroplasty
- gastric outlet obstruction:
 - etiology: ulcer can lead to edema, fibrosis of pyloric channel, neoplasm
 - clinical presentation:
 - ♦ nausea and vomiting (undigested food, non-bilious), dilated stomach, crampy abdominal pain
 - ♦ succussion splash (splashing noise heard when patient is shaken)
 - ♦ auscultate gas and fluid movement in obstructed organ

- treatment:
 - ♦ NG decompression and correction of hypochloremic, hypokalemic metabolic alkalosis
 - ♦ medical management initially: high dose PPI therapy
 - ♦ if obstruction does not resolve, consider surgical resection: either Billroth I, pyloroplasty or gastrojejunostomy to bypass

Surgical Treatment

- surgical indications:
 - hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
 - ♦ decision to operate based on amount of blood loss (usually >8 units), rate of bleeding and hemodynamic stability
 - intractable despite medical management (endoscopy)
- procedures:
 - oversewing of ulcer, pyloroplasty
 - vagotomy
 - ♦ rarely done now due to *H. pylori* eradication

Complications of Surgery

- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome (see *Complications of Gastric Surgery*, GS19)

Gastric Carcinoma

Epidemiology

- male:female = 3:2
- incidence for adenocarcinoma = 10 per 100,000, incidence highest in Asia (Japan 80 times higher than in U.S.)
- most common age group = 50-59 years
- incidence has decreased by 2/3 in past 50 years

Risk Factors

- *H. pylori*, causing chronic atrophic gastritis
- hereditary nonpolyposis colorectal cancer (HNPCC)
- smoking, alcohol, smoked food, nitrosamines
- pernicious anemia associated with achlorhydria and chronic atrophic gastritis
- gastric adenomatous polyps
- previous partial gastrectomy (>10 years post-gastrectomy)
- hypertrophic gastropathy
- blood type A

Clinical Features

- clinical suspicion:
 - ulcer fails to heal
 - lesion on greater curvature of stomach or cardia
- asymptomatic, insidious or late onset of symptoms:
 - postprandial abdominal fullness, vague epigastric pain
 - anorexia, weight loss
 - burping, nausea, vomiting, dyspepsia, dysphagia
 - hepatomegaly, epigastric mass (25%)
 - hematemesis, fecal occult blood, melena, iron-deficiency anemia
- signs of metastatic disease:
 - Virchow's node – left supraclavicular node
 - Blumer's shelf – mass in pouch of Douglas
 - Krukenberg tumour – metastases to ovary
 - Sister Mary Joseph node – umbilical metastases
 - Irish's node – left axillary nodes
- metastasis:
 - liver, lung, brain

Investigations

- OGD and biopsy
- chest/abdo/pelvis CT
- CT for metastatic work-up (see Table 4)

Figure 8. Billroth I and Billroth II with Roux-en-Y Reconstruction (gastrojejunostomy)

Table 4. Staging of Gastric Carcinoma

Stage	Criteria	Prognosis (5-year survival)
I	Mucosa and submucosa	70%
II	Extension to muscularis propria	30%
III	Extension to regional nodes	10%
IV	Distant metastases or involvement of continuous structures	0%

Treatment

- adenocarcinoma:
 - proximal lesions:
 - ♦ total gastrectomy and esophagojejunostomy – Roux-en-Y (see Figure 8)
 - distal lesions:
 - ♦ distal gastrectomy: wide margins, en bloc removal of omentum and lymph nodes
 - palliation:
 - ♦ gastric resection to decrease bleeding and relieve obstruction, enables the patient to eat
 - ♦ radiation therapy
 - ♦ studies are showing larger role for chemotherapy
- lymphoma:
 - chemotherapy ± radiation, surgery in limited cases (perforation, bleeding, obstruction)

Gastric Sarcoma

Gastrointestinal Stromal Tumour (GIST)

- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach's plexus that have autonomous pacemaker function co-ordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%), and proximal small intestine (25%), but can occur anywhere along GI tract
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- often discovered incidentally on CT, laparotomy or endoscopy

Risk Factors

- Carney's Triad: GISTs, paraganglioma, and pulmonary chondroma
- Type IA neurofibromatosis

Management

- surgical resection if >2 cm; follow with serial endoscopy if <2 cm then resect if growing or symptomatic
- pre-operative biopsy: controversial, but useful for indeterminate lesions:
 - not recommended if index of suspicion for GIST is high
 - percutaneous biopsy is NOT recommended due to high friability and risk of peritoneal spread
- localized GIST: surgical resection with preservation of intact pseudocapsule
 - lymphadenectomy NOT recommended, as GISTs rarely metastasize to lymph nodes
- advanced disease: metastases to liver and/or peritoneal cavity:
 - chemotherapy with imatinib mesylate (tyrosine kinase inhibitor)
 - current research looking into role of imatinib as adjuvant or neoadjuvant therapy for localized GIST

Prognosis

- risk of metastatic potential depends on:
 - tumour size (worse if >10 cm)
 - mitotic activity (worse if >5 mitotic figures or 50/hpf)
 - degree of nuclear pleomorphism
 - location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
 - mets to liver, omentum, peritoneum; nodal mets rare

Bariatric Surgery

- weight reduction surgery for morbid obesity
- indications: BMI >40 or BMI >35 with related comorbidity (e.g. DM, CAD)
- requires multidisciplinary evaluation and follow-up

Bariatric (Weight Loss) Surgery for Obesity is considered when Other Treatments have Failed
Benefits

- Greater weight loss in patients with BMI >30 at 2 years
- Reduction in co-morbidities (Type II diabetes, hypertension and medication use)
- Improvement in quality of life at 2 years (physical function, physical role, general health, vitality and emotional role)

Risks

- Complications: leaks, hernias, infection, pulmonary embolism, postoperative mortality
- Side effects specific to type of procedure (i.e. vomiting, dumping syndrome, food intolerance)
- Cholecystitis occurs as a result of rapid weight loss

Colquitt JL, Picot J, Loveman E, Clegg AJ. Surgery for Obesity (Cochrane Review). In: *The Cochrane Library*, Issue 2, 2009. Chichester, UK: John Wiley & Sons, Ltd.

Surgical Options

- malabsorptive/restrictive:
 - laparoscopic Roux-en-Y gastric bypass (most common)
 - staple off small gastric pouch (restrictive) with Roux-en-Y limb to pouch (malabsorptive) with dumping syndrome physiology
 - most effective, higher complication rates
- restrictive:
 - laparoscopic adjustable gastric banding
 - silicone band around fundus creates pouch, adjustable through port under skin
 - laparoscopic vertical banded gastroplasty
 - vertical stapled small gastric pouch with placement of silastic ring band
- malabsorptive:
 - biliopancreatic diversion with duodenal switch
 - gastrectomy, enteroenterostomy, duodenal division closure and duodenoenterostomy

Complications

- perioperative mortality ~1% (anastomotic leak with peritoneal signs, PE)
- obstruction at enteroenterostomy (see *Complications of Gastric Surgery*, below)
- staple line dehiscence
- dumping syndrome
- cholethiasis due to rapid weight loss (20-30%)
- band abscess (if long-term)

Complications of Gastric Surgery

- most resolve within 1 year (see Figure 9)

Alkaline Reflux Gastritis (see Figure 9A)

- duodenal contents (bilious) reflux into stomach causing gastritis ± esophagitis
- treatment:
 - medical: H₂-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
 - surgical: conversion of Billroth I or II to Roux-en-Y

Afferent Loop Syndrome (see Figure 9B)

- accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
- clinical features:
 - early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
- treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

Dumping Syndrome (see Figure 9C)

- early – 15 minutes post-prandial:
 - etiology:
 - hyperosmotic chyme released into small bowel (fluid accumulation and jejunal distention)
 - clinical features:
 - post-prandial symptoms
 - epigastric fullness or pain, emesis, nausea, diarrhea, palpitations, dizziness, tachycardia, diaphoresis
 - treatment:
 - small multiple low carbohydrate, low fat and high protein meals and avoidance of liquids with meals
 - last resort is interposition of antiperistaltic jejunal loop between stomach and small bowel to delay gastric emptying
- late – 3 hours post-prandial:
 - etiology: large glucose load leads to large insulin release and hypoglycemia
 - treatment: small snack 2 hours after meals

Blind-Loop Syndrome (see Figure 9D)

- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features:
 - anemia/weakness, diarrhea, malnutrition, abdominal pain and hypocalcemia
- treatment: broad-spectrum antibiotics, surgery (conversion to Billroth I)

Postvagotomy Diarrhea (see Figure 9E)

- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine), surgical (reversed interposition jejunal segment)

Figure 9. Complications of Gastric Surgery
© Wensi Sheng 2010

Small Intestine

Meckel's Diverticulum

- remnant of the embryonic vitelline duct on antimesenteric border of ileum
- heterotopic – several types of mucosa including gastric, pancreatic, colonic
- most common true diverticulum of GI tract

Clinical Features

- 2% symptomatic
- GI bleed, small bowel obstruction (SBO), diverticulitis (mimics appendicitis)
- painless bleeding – ulceration caused by ectopic gastric mucosa
 - 50% of patients with this presentation are <2 years old

Investigations

- technetium-99 to identify the ectopic gastric mucosa (Meckel's scan)

Complications

- fistula: umbilicus-ileum, umbilical sinus
- fibrous cord between umbilicus and ileum
- SBO due to volvulus, intussusception, perforation

Treatment

- incidental finding – consider surgical resection
- symptomatic – fluid and electrolyte stabilization and surgical resection
- broad based – segmental resection to remove all mucosal types and ulcerated mucosa opposite the diverticulum (i.e. not simple diverticulectomy)

Rule of 2s for Meckel's Diverticulum

- 2% of the population
- Symptomatic in 2% of cases
- Found within 2 feet (10-90 cm) of the ileocecal (IC) valve
- 2 inches in length
- Often present by 2 years of age

Tumours of Small Intestine

Risk Factors

- carcinogen exposure (red meat in diet)
- familial adenomatous polyposis (FAP), Peutz-Jegher syndrome, Gardner's syndrome
- Crohn's disease, celiac disease
- immunodeficiency, autoimmune disorders

Clinical Features

- usually asymptomatic until advanced
- intermittent obstruction, intussusception, occult bleeding, palpable abdominal mass, abdominal pain

BENIGN TUMOURS

- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum, proximal jejunum
- polyps:
 - adenomas
 - familial adenomatous polyposis (FAP) (see *Familial Colon Cancer Syndromes*, GS33)
 - hamartomatous
 - juvenile polyps
- other: leiomyomas, lipomas, hemangiomas

MALIGNANT TUMOURS

- usually asymptomatic until advanced stage
 - 25-30% associated with distant metastases at time of diagnosis
- adenocarcinoma:
 - most common primary tumour of small intestine
 - usually 50-70 years old, male predominance
 - usually in proximal small bowel, incidence decreases distally
 - risk factors: Crohn's disease, FAP
 - early metastasis to lymph nodes – 80% metastatic at time of operation
 - investigations – CT abdo/pelvis, endoscopy
 - treatment – surgical resection ± chemotherapy
 - 5-year survival 25%

Malignant Tumours

Adenocarcinoma	Most common
Carcinoid	
Lymphoma	
Sarcoma	Least common

- **carcinoid:**

- increased incidence 50-60 years old
- originate from enterochromaffin cell in crypts
- most commonly 60 cm from the ileocecal (IC) valve
 - ♦ appendix 46%, distal ileum 28%, rectum 17%
- often slow-growing
- classified by embryological origin (correlate with morphology, biological behaviour):
 - ♦ foregut – stomach, duodenum, pancreas
 - ♦ midgut – jejunum, ileum, appendix, ascending colon
 - ♦ hindgut – transverse, descending and sigmoid colon, rectum
- clinical features:
 - ♦ usually asymptomatic, incidental finding
 - ♦ obstruction, bleeding, crampy abdominal pain, intussusception
 - ♦ carcinoid syndrome (<10%):
 - hot flashes, hypotension, diarrhea, bronchoconstriction (wheezing), tricuspid/pulmonic valve insufficiency, right heart failure
 - requires liver involvement: lesion secretes serotonin, kinins and vasoactive peptides directly to systemic circulation (normally inactivated by liver)
 - EXCEPTION: carcinoid tumours arising in the bronchi can cause carcinoid syndrome without liver involvement because of access to systemic circulation
- investigations:
 - ♦ most found incidentally at surgery for obstruction or appendectomy
 - ♦ elevated 5-HIAA (breakdown product of serotonin) in urine or increased 5-HT in blood
- treatment:
 - ♦ tumour and metastases: surgical resection ± chemotherapy
 - ♦ carcinoid syndrome: steroids, histamine, octreotide
- prognosis:
 - ♦ metastatic risk 2% if size <1 cm, 90% if >2 cm
 - ♦ 5-year survival 70%; 20% with liver metastases

- **lymphoma:**

- highest incidence at 70 years old, more common in males
- usually non-Hodgkin's lymphoma
- location:
 - ♦ usually distal ileum
 - ♦ proximal jejunum in patients with celiac disease
- clinical features:
 - ♦ fatigue, weight loss, abdominal pain, fever, malabsorption
 - ♦ rarely – perforation, obstruction, bleeding, intussusception
- treatment:
 - ♦ low grade: chemotherapy with cyclophosphamide
 - ♦ high grade: surgical resection, radiation
 - ♦ palliative: somatostatin, doxorubicin
- 5-year survival 40%

- **metastatic:**

- most common site of GI metastases in patients with metastatic melanoma
- hematogenous spread from breast, lung, kidney
- direct extension from cervix, ovaries, colon

- **gastrointestinal stromal tumours (GISTs):**

- see *Gastric Sarcoma* section, GS18

Symptoms of Carcinoid Syndrome

Flushing
Diarrhea
Right-sided heart failure

Ability of Somatostatin Receptor Scintigraphy to Identify Patients with Gastric Carcinoids: A Prospective Study

J Nucl Med 2000; 41(10):1646-56

Background: Carcinoid tumours are challenging cancers to identify, with low detection rates achieved by conventional radiologic imaging modalities. Somatostatin receptor scintigraphy (SRS) is a new imaging modality which has been shown to have improved rates of detection of carcinoid tumours compared to conventional imaging studies. The purpose of this study was to determine the sensitivity and specificity of SRS in identifying gastric carcinoids.

Methods: 162 consecutive patients with Zollinger-Ellison syndrome (ZES) were studied prospectively. Patients were investigated by annual SRS with SPECT, upper gastrointestinal endoscopy, and direct biopsies of any detected gastric abnormalities, as well as random gastric tissue biopsies. Results of SRS were correlated with the gastric biopsy results.

Results: Gastric SRS localization was positive in 19 (12%) of 162 patients. Sixteen patients had a gastric carcinoid, and 12 of these patients had SRS localization. The sensitivity of SRS in localizing a gastric carcinoid was 75%, with a specificity of 95%. Positive and negative predictive values were 63% and 97%, respectively.

Conclusion: SRS is a noninvasive method which can be used to identify gastric carcinoid tumours with high specificity and reasonable sensitivity.

Hernia

Definition

- fascial defect → protrusion of a viscus into an area in which it is not normally contained

Epidemiology

- male:female = 9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- 50% are indirect inguinal hernia, 25% are direct inguinal hernia, 5% are femoral
- most common surgical disease of males

Risk Factors

- activities which increase intra-abdominal pressure:
 - obesity, chronic cough, pregnancy, constipation, straining on urination or defecation, ascites, heavy lifting
- congenital abnormality (e.g. patent processus vaginalis)
- previous hernia repair

Figure 10. Normal Inguinal Anatomy

Figure 11. Richter's Hernia

Clinical Features

- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

Investigations

- physical examination usually sufficient
- ultrasound \pm CT

Classification

- complete – hernia sac and contents protrude through defect
- incomplete – partial protrusion through the defect
- internal hernia – sac herniating into or involving intra-abdominal structure
- external hernia – sac protrudes completely through abdominal wall
- strangulated hernia – vascular supply of protruded viscus is compromised (ischemia)
 - requires **emergency** repair
- incarcerated hernia – irreducible hernia, not necessarily strangulated
- Richter's hernia – only part of circumference of bowel (usually anti-mesenteric border) is incarcerated or strangulated so may not be obstructed
 - a strangulated Richter's hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation
- sliding hernia – part of wall of hernia formed by protruding viscus (usually cecum, sigmoid colon, bladder)

Anatomical Types

- groin (see Tables 5 and 6)
 - indirect and direct inguinal, femoral (see Figure 12)
 - pantaloon: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastric: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Littre's (involving Meckel's), Amyand's (containing ruptured appendix), lumbar, obturator, parastomal, umbilical, Spigelian (ventral hernia through linea semilunaris)

Complications

- incarceration: irreducible
- strangulation: irreducible with resulting ischemia:
 - small, new hernias more likely to strangulate
 - femoral \gg indirect inguinal $>$ direct inguinal
 - intense pain followed by tenderness
 - intestinal obstruction, gangrenous bowel, sepsis
 - surgical emergency
 - **DO NOT** attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous

Treatment

- surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration or for cosmesis or symptoms; if asymptomatic can delay surgery
- repair may be done open or laparoscopic and may use mesh for tension-free closure
- most repairs are now done with a plug in the hernial defect and a patch over it or patch alone
- observation is acceptable for small asymptomatic inguinal hernias

Postoperative Complications

- recurrence (15-20%):
 - risk factors: recurrent hernia, age >50 , smoking, BMI >25 , poor pre-op functional status (ASA ≥ 3 – see [Anaesthesia](#), A4), associated medical conditions: type II DM, hyperlipidemia, immunosuppression, any comorbid conditions increasing intra-abdominal pressure
 - less common with mesh/"tension-free" repair
- scrotal hematoma (3%):
 - painful scrotal swelling from compromised venous return of testes
 - deep bleeding – may enter retroperitoneal space and not be initially apparent
 - difficulty voiding
- nerve entrapment:
 - ilioinguinal
 - genital branch of genitofemoral (in spermatic cord)
- stenosis/occlusion of femoral vein:
 - acute leg swelling
- ischemic colitis

Groin Hernias

Table 5. Groin Hernias

	Direct Inguinal	Indirect Inguinal	Femoral
Epidemiology	1% of all men	Most common hernia in men and women Males > females	Affects mostly females
Etiology	Acquired weakness of transversalis fascia "Wear and tear" Increased intra-abdominal pressure	Congenital persistence of processus vaginalis in 20% of adults	Pregnancy – weakness of pelvic floor musculature Increased intra-abdominal pressure
Anatomy	Through Hesselbach's triangle Medial to inferior epigastric artery Usually does not descend into scrotal sac	Originates in deep inguinal ring Lateral to inferior epigastric artery Often descends into scrotal sac (or labia majora)	Into femoral canal, below inguinal ligament but may override it Medial to femoral vein within femoral canal
Treatment	Surgical repair	Surgical repair	Surgical repair
Prognosis	3-4% risk of recurrence	<1% risk of recurrence	

Table 6. Superficial Inguinal Ring vs. Deep Inguinal Ring

Superficial Inguinal Ring	Deep Inguinal Ring
Opening in ext. abdominal aponeurosis; palpable superior and lateral to pubic tubercle	Opening in transversalis fascia; palpable superior to mid-inguinal ligament
Medial border: medial crus of ext. abdominal aponeurosis	Medial border: inf. epigastric vessels
Lateral border: lateral crus of ext. oblique aponeurosis	Superior-lateral border: internal oblique and transversus abdominis muscles
Roof: intercrural fibres	Inferior border: inguinal ligament

Bowel Obstruction

Definition

- partial or complete blockage of the bowel resulting in failure of intestinal contents to pass through lumen

Pathogenesis

- disruption of the normal flow of intestinal contents → proximal dilation + distal decompression
- may take 12-24 hrs to decompress, therefore passage of feces and flatus may occur after the onset of obstruction
- bowel ischemia may occur if blood supply is strangulated or bowel wall inflammation leads to venous congestion
- bowel wall edema and disruption of normal bowel absorptive function → increased intraluminal fluid → transudative fluid loss into peritoneal cavity, electrolyte disturbances

Differential Diagnosis

- small bowel obstruction (SBO), large bowel obstruction (LBO), pseudo-obstruction

Clinical Features

- must differentiate between obstruction and ileus, and characterize obstruction as acute vs. chronic, partial vs. complete (constipation vs. obstipation), small vs. large bowel, strangulating vs. non-strangulating, and with vs. without perforation

Table 7. Bowel Obstruction vs. Paralytic Ileus

	SBO	LBO	Paralytic ileus
Nausea, Vomiting	Early, may be bilious	Late, may be feculent	Present
Abdominal Pain	Colicky	Colicky	Minimal or absent
Abdominal Distention	+ (prox) < ++ (distal)	++	+
Constipation	+	+	+
Other	± visible peristalsis	± visible peristalsis	
Bowel Sounds	Normal, increased Absent if secondary ileus	Normal, increased (borborygmi) Absent if secondary ileus	Decreased, absent
AXR Findings	Air-fluid levels "Ladder" pattern (plicae circularis) Proximal distention (>3 cm) + no colonic gas	Air-fluid levels "Picture frame" appearance Proximal distention + distal decompression No small bowel air if competent ileocecal valve Coffee bean sign	Air throughout small bowel and colon

Contents of Spermatic Cord

vas deferens, testicular artery/veins, genital branch of genitofemoral nerve, lymphatics, cremaster muscle, ± hernia sac

Indirect hernia

Direct hernia

Femoral hernia

© Jason Sharpe 2003

Figure 12. Schematic of Inguinal (Direct and Indirect) and Femoral Hernias

Complications (of total obstruction)

- strangulating obstruction (10% of bowel obstructions) = **surgical emergency**:
 - cramping pain turns to continuous ache, hematemesis, melena (if infarction)
 - fever, leukocytosis, tachycardia
 - peritoneal signs, early shock
 - see also *Intestinal Ischemia*, GS27
- other:
 - perforation: secondary to ischemia and luminal distention
 - septicemia
 - hypovolemia (due to third spacing)

**Increased Risk of Perforation with Distention as seen on Abdo Imaging**

Small bowel ≥ 3 cm
Distal colon ≥ 6 cm
Proximal colon ≥ 9 cm
Cecum ≥ 12 cm

Investigations

- radiological:
 - upright CXR or left lateral decubitus (LLD) to rule out free air, usually seen under the right hemidiaphragm
 - abdominal x-ray (3 views) to determine SBO vs. LBO vs. ileus (see Table 7)
 - ♦ if ischemic bowel look for: free air, pneumatosis, thickened bowel wall, air in portal vein, dilated small and large bowels, thickened or hose-like haustra (normally fingerlike projections)
 - other:
 - ♦ CT provides information on level of obstruction, severity, cause
 - ♦ upper GI series/small bowel series for SBO (if no cause apparent, i.e. no hernias, no previous surgeries)
 - ♦ if suspect LBO, consider a rectal water-soluble (Gastrografin® for PO/PR; Hypaque® for IV) enema rather than barium enema (can thicken and cause complete obstruction)
 - ♦ may consider ultrasound or MRI in pregnant patients
- laboratory:
 - may be normal early in disease course
 - BUN, creatinine, hematocrit (hemoconcentration) to assess degree of dehydration
 - fluid, electrolyte abnormalities
 - amylase elevated
 - metabolic alkalosis due to frequent emesis
 - if strangulation: leukocytosis with left shift, lactic acidosis, elevated LDH (late signs)

Treatment

- stabilize vitals, fluid and electrolyte resuscitation (with normal saline/Ringer's first, then with added potassium after fluid deficits are corrected)
- NG tube to relieve vomiting, prevent aspiration and decompress small bowel by prevention of further distention by swallowed air
- Foley catheter to monitor in/outs

Small Bowel Obstruction (SBO)

Etiology**Table 8. Common Causes of SBO**

Intraluminal	Intramural	Extramural
Intussusception	Crohn's	Adhesions
Gallstones	Radiation stricture	Incarcerated hernia
	Adenocarcinoma	Peritoneal carcinomatosis

Treatment

- consider whether complete or partial obstruction, ongoing or impending strangulation, location and cause:
 - SBO with history of abdo/pelvic surgery → conservative management (likely to resolve) → surgery if no resolution in 48-72 hrs or complications
 - complete SBO, strangulation → urgent surgery after stabilizing patient
 - trial of medical management may be indicated in Crohn's, recurrent SBO, carcinomatosis
 - special case: early postoperative SBO (within 30 days of abdominal surgery) – prolonged trial of conservative therapy is appropriate, surgery is reserved for complications such as strangulation

Prognosis

- mortality: non-strangulating <1%, strangulating 8% (25% if >36 hours), ischemic = up to 50%

**Top 3 Causes of SBO (in order)****ABC**

1. Adhesions
2. Bulge (hernias)
3. Cancer (neoplasms)

Large Bowel Obstruction (LBO)

Etiology

Table 9. Common Causes of LBO

Intraluminal	Intramural	Extramural
Constipation	Adenocarcinoma Diverticulitis IBD stricture Radiation stricture	Volvulus

Top 3 Causes of LBO (in order)

1. Cancer
2. Diverticulitis
3. Volvulus

Clinical Features (unique to LBO)

- open loop (10-20%) (safe):
 - incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical presentation similar to SBO
- closed loop (80-90%) (**dangerous**):
 - competent ileocecal valve, resulting in proximal and distal occlusions
 - massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

In a patient with clinical LBO consider impending perforation when:

- Cecum ≥ 12 cm in diameter
- Tenderness present over cecum

Treatment

- surgical correction of obstruction (usually requires resection + temporary diverting colostomy)
- volvulus requires sigmoidoscopic or endoscopic decompression followed by operative reduction if unsuccessful
 - if successful, consider sigmoid resection on same admission

Prognosis

- overall mortality: 10%
- cecal perforation + feculent peritonitis: 20% mortality

Pseudo-Obstruction

Definition

- condition with symptoms of intestinal blockage without any physical signs of blockage

Differential Diagnosis

- acute: toxic megacolon, trauma, postoperative, neurologic disease, retroperitoneal disease
- chronic: neurologic disease (enteric, central, peripheral nervous system), scleroderma

Toxic Megacolon

Pathogenesis

- extension of inflammation into smooth muscle layer causing paralysis
- damage to myenteric plexus and electrolyte abnormalities are not consistently found

Etiology

- inflammatory bowel disease (ulcerative colitis > Crohn's Disease)
- infectious colitis: bacterial (*C. difficile*, *Salmonella*, *Shigella*, *Campylobacter*), viral (cytomegalovirus), parasitic (*E. histolytica*)
- volvulus, diverticulitis, ischemic colitis, obstructing colon cancer are rare causes

Clinical Features

- infectious colitis usually present for >1 week before colonic dilatation
- diarrhea \pm blood (but improvement of diarrhea may portend onset of megacolon)
- abdominal distention, tenderness, \pm local/general peritoneal signs (suggest perforation)
- triggers: hypokalemia, constipating agents (opioids, antidiarrheals, loperamide, anticholinergics), barium enema, colonoscopy

Diagnostic Criteria

- must have both colitis and systemic manifestations for diagnosis
- radiologic evidence of dilated colon
- **three of:** fever, HR >120, WBC >10.5, anemia
- **one of:** fluid and electrolyte disturbances, hypotension, altered LOC

Use caution when giving antidiarrheals, especially with bloody diarrhea.

Investigations

- CBC (leukocytosis with left shift, anemia from bloody diarrhea), electrolytes, elevated CRP, ESR
- metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings
- AXR: dilated colon >6 cm (right > transverse > left), loss of haustra
- CT: useful to assess underlying disease

Treatment

- NPO, NG tube, stop constipating agents, correct fluid and electrolyte abnormalities, transfusion
- serial AXRs
- broad-spectrum antibiotics (reduce sepsis, anticipate perforation)
- aggressive treatment of underlying disease (e.g. steroids in IBD, metronidazole for *C. difficile*)
- indications for surgery (50% improve on medical management):
 - worsening or persisting toxicity or dilation after 48-72 hrs
 - severe hemorrhage, perforation
- procedure: subtotal colectomy + end ileostomy with 2nd operation for re-anastomosis

Prognosis

- average 25-30% mortality

Paralytic Ileus

Pathogenesis

- temporary paralysis of the myenteric plexus

Associations

- postoperative, intra-abdominal sepsis, medications (opiates, anesthetics, psychotropics), electrolyte disturbances (Na, K, Ca), *C. difficile*, inactivity

Treatment

- NG decompression, NPO, fluid resuscitation, correct causative abnormalities (e.g. sepsis, medications, electrolytes), consider TPN for prolonged ileus
- post-op: gastric and small bowel motility returns by 24-48 hrs, colonic motility by 3-5 d
- current interest in novel therapies such as gum chewing and pharmacologic therapy (opioid antagonists, neostigmine)

Ogilvie's Syndrome

- acute pseudo-obstruction
- distention of colon without mechanical obstruction in distal colon
- arises in bedridden patients with serious extraintestinal illness or trauma
- exact mechanism unknown, likely autonomic motor dysregulation → possibly sympathetic deprivation to colon, unopposed parasympathetic tone, and interruption of sacral parasympathetic tone to distal bowel
- first presents with abdominal distention (>90%) ± tenderness
- later symptoms mimic true obstruction

Associations

- most common: trauma, infection, cardiac (MI, CHF)
- disability (long term debilitation, chronic disease, bed-bound nursing home patients, paraplegia), drugs (narcotic use, laxative abuse, polypharmacy), other (recent orthopaedic or neurosurgery, post-partum, hypokalemia, retroperitoneal hematoma, diffuse carcinomatosis)

Investigations

- AXR: cecal dilatation – if diameter ≥ 12 cm, increased risk of perforation

Treatment

- treat underlying cause
- NPO, NG tube
- decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), surgical decompression (ostomy/resection) uncommon
- surgery (extremely rare): if perforation, ischemia or failure of conservative management

Prognosis

- most resolve with conservative management

Intestinal Ischemia

Etiology

- acute:
 - arterial:
 - ♦ occlusive: thrombotic, embolic, extrinsic compression (e.g. strangulating hernia)
 - ♦ non-occlusive: mesenteric vasoconstriction 2° to systemic hypoperfusion (preserves supply to vital organs)
 - ♦ trauma/dissection
 - venous thrombosis (prevents venous outflow): consider hypercoagulable state, deep vein thrombosis (DVT)
- chronic: usually due to atherosclerotic disease – look for CVD risk factors

Clinical Features

- acute: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, sepsis
- chronic: postprandial pain, fear of eating, weight loss
- common sites: superior mesenteric artery (SMA) supplied territory, “watershed” areas of colon – splenic flexure, left colon, sigmoid colon

Investigations

- labs: leukocytosis (non-specific), lactic acidosis (late finding)
 - amylase, LDH, CK, ALP can be used to observe progress
 - hypercoagulability workup if suspect venous thrombosis
- AXR: portal venous gas, intestinal pneumatosis, free air if perforation
- contrast CT: thickened bowel wall, luminal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, pneumatosis
- CT angiography is the gold standard for acute arterial ischemia

Treatment

- fluid resuscitation, NPO, prophylactic broad-spectrum antibiotics
- exploratory laparotomy
- angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, anticoagulation therapy
- segmental resection of necrotic intestine:
 - assess extent of viability; if extent of bowel viability is uncertain, a second look laparotomy 12-24 hrs later is mandatory

Pain “out of keeping with physical findings” is the hallmark of early intestinal ischemia.

An acute abdomen + metabolic acidosis is bowel ischemia until proven otherwise.

Appendix

Appendicitis

Epidemiology

- 6% of population, M>F
- 80% between 5-35 years of age

Pathogenesis

- luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
- etiology:
 - children or young adult: hyperplasia of lymphoid follicles, initiated by infection
 - adult: fibrosis/stricture, fecolith, obstructing neoplasm
 - other causes: parasites, foreign body

Clinical Features

- most reliable feature is progression of signs and symptoms
- low grade fever (38°C), rises if perforation
- abdominal pain then anorexia, nausea and vomiting
- classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well localized pain over McBurney's point
 - due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
 - McBurney's sign

Figure 13. Appendix Anatomy

McBurney's Sign
Tenderness 1/3 the distance from the ASIS to the umbilicus on the right side.

Laparoscopic vs. Open Appendectomy**Laparoscopic Surgery**

- Intra-abdominal abscesses 3 times more likely
- Mean length of hospital stay reduced by 0.7 d
- Sooner return to normal activity, work and sport
- Costs outside hospital are reduced
- Reduced levels of pain on POD #1

Open Surgery

- Wound infections 2 times as likely
- Lower operation costs

Overview

Diagnostic laparoscopy led to a large reduction in the rate of negative appendectomies, and a reduction in surgeries with unestablished diagnosis. This was especially pronounced in fertile women due to a broader differential for appendicitis.

Sauerland S, Lefering R, Neugebauer EAM. Laparoscopic versus open surgery for suspected appendicitis (Cochrane Review). In: *The Cochrane Library*, Issue 3, 2004. Chichester, UK: John Wiley & Sons, Ltd.

Antibiotics versus Placebo for Prevention of Postoperative Infection after Appendectomy

Cochrane Database of Systematic Reviews 2005; 3

Study: Meta-analysis of Randomised Controlled Trials (RCTs) and Controlled Clinical Trials (CCTs), on both adults and children, in which any antibiotic regime was compared to placebo in patients undergoing appendectomy for suspected appendicitis.

Data Sources: Cochrane Central Register of Controlled Trials (2005 issue 1), PubMed (1966 to April 2005), EMBASE (1980 to April 2005), Cochrane Colorectal Cancer Group Specialised Register (April 2005), and reference lists from included studies.

Patients: Wound infection, 20 studies (n=2343). Postoperative Intra-abdominal abscess, 8 studies (n=1033).

Main Outcomes: (1) Wound infection (discharge of pus from the wounds) and (2) Postoperative intra-abdominal abscess (persistent pyrexia without any other focus, after operation, palpable mass in the abdomen or discharge of pus from the rectum).

Results: Treatment with antibiotics decreased infection rates with an NNT=37 ($p<0.00001$), while treatment with antibiotics decreased abscess rates with an NNT=199 ($p=0.03$).

Conclusion: Various prophylactic antibiotic regimens are effective in preventing postoperative complications. Further studies are required to determine the ideal regimen.

- signs:
 - inferior appendix: McBurney's sign (see above), Rovsing's sign (palpation pressure to left abdomen causes McBurney's point tenderness)
 - retrocecal appendix: psoas sign (pain on flexion of hip against resistance or passive hyperextension of hip)
 - pelvic appendix: obturator sign (flexion then external or internal rotation about right hip causes pain)
- complications:
 - perforation (especially if >24 hrs duration)
 - abscess, phlegmon

Investigations

- labs:
 - mild leukocytosis with left shift (may have normal WBC counts)
 - higher leukocyte count with perforation
 - beta-hCG to rule out ectopic pregnancy
 - urinalysis
- imaging:
 - upright CXR, AXR: usually nonspecific – free air if perforated (rarely), calcified fecolith, loss of psoas shadow
 - ultrasound: may visualize appendix, but also helps rule out gynecological causes – overall accuracy 90-94%
 - CT scan: thick wall, appendicolith, inflammatory changes – overall accuracy 94-100%, optimal investigation

Treatment

- hydrate, correct electrolyte abnormalities
- surgery + antibiotic coverage
- if localized abscess (palpable mass or large phlegmon on imaging and often pain >4-5 days), consider radiologic drainage + antibiotics x 14 d + interval appendectomy in 6 weeks
- appendectomy:
 - laparoscopic vs. open (see sidebar)
 - complications: spillage of bowel contents, pelvic abscess, enterocutaneous fistula
 - perioperative antibiotics:
 - ♦ ampicillin + gentamicin + metronidazole (antibiotics x 24 h only if non-perforated)
 - ♦ other choices: 2nd/3rd generation cephalosporin for aerobic gut organisms

Prognosis

- morbidity/mortality 0.6% if uncomplicated, 5% if perforated

Tumours of the Appendix

CARCINOID TUMOURS (most common type)

- see *Tumours of Small Intestines: Carcinoid*, GS21

ADENOCARCINOMA

- 50% present as acute appendicitis
- spreads rapidly to lymph nodes, ovaries, and peritoneal surfaces
- treatment: right hemicolectomy

OTHER

- malignant mucinous cystadenocarcinoma

Inflammatory Bowel Disease (IBD)

- see *Gastroenterology*, G19

Principles of Surgical Management

- can alleviate symptoms, address complications, improve quality of life
- conserve bowel – resect as little as possible to avoid short gut syndrome
- perioperative management:
 - optimize medical status: may require TPN (especially if >7 days NPO) and bowel rest
 - hold immunosuppressive therapy pre-op, provide pre-op stress dose of corticosteroid if patient had recent steroid therapy
 - deep vein thrombosis (DVT) prophylaxis: heparin (IBD patients at increased risk of thromboembolic events)

Crohn's Disease

Treatment

- surgery is NOT curative, but over lifetime ~70% of Crohn's patients will have surgery
- indications for surgical management:
 - failure of medical management
 - SBO (due to stricture/inflammation): indication in 50% of surgical cases
 - abscess, fistula (enterocolic, vesicular, vaginal, cutaneous abscess), quality of life, perforation, hemorrhage, chronic disability, failure to thrive (children), perianal disease
- surgical procedures:
 - resection and anastomosis/stoma if active or subacute inflammation, perforation, fistula
 - ♦ resection margin only has to be free of gross disease (microscopic disease irrelevant to prognosis)
 - stricturoplasty – widens lumen in chronically scarred bowel – relieves obstruction without resecting bowel (contraindicated in acute inflammation)

Crohn's 3 Major Patterns

- Ileocecal 40% (RLQ pain, fever, weight loss)
- Small intestine 30% (especially terminal ileum)
- Colon 25% (diarrhea)

Complications of Treatment

- short gut syndrome (diarrhea, steatorrhea, malnutrition)
- fistulas
- gallstones (if terminal ileum resected, decreased bile salt resorption → increased cholesterol precipitation)
- kidney stones (loss of calcium in diarrhea → increased oxalate absorption and hyperoxaluria → stones)

Findings in Crohn's

- "Cobblestoning" on mucosal surface due to edema and linear ulcerations
- "Skip lesions": normal mucosa in between
- "Creeping fat": mesentery infiltrated by fat
- Granulomas: 25-30%
- Barium enema: "lead-pipe appearance"

Prognosis

- recurrence rate at 10 years: ileocolic (25-50%), small bowel (50%), colonic (40-50%)
- re-operation at 5 years: primary resection (20%), bypass (50%), stricturoplasty (10% at 1 year)
- 80-85% of patients who need surgery lead normal lives
- mortality: 15% at 30 years

Ulcerative Colitis

Treatment

- indications for surgical management:
 - failure of medical management (including inability to taper steroids)
 - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
 - reduce cancer risk (1-2% risk per year after 10 years of disease)
- surgical procedures:
 - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
 - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
 - colectomy and IPAA ± rectal mucosectomy
 - in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

Complications of Treatment

- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

Prognosis

- mortality: 5% over 10 years
- total proctocolectomy will completely eliminate risk of cancer
- perforation of the colon is the leading cause of death from ulcerative colitis

Diverticular Disease

Definitions

- diverticulum – abnormal sac or pouch protruding from the wall of a hollow organ
- diverticulosis – presence of multiple false diverticuli
- diverticulitis – inflammation of diverticuli
- right sided (true) diverticuli = contains all layers (congenital) (see Figure 14)
- left sided (false) diverticuli = contains only mucosal and submucosal layers (acquired)

Figure 14. Diverticular Disease – Cross-Sections of True and False Diverticuli

Diverticulosis

Epidemiology

- 35-50% of general population, M=F
- increased incidence in 5th to 8th decades of life
- 95% involve sigmoid colon (site of highest pressure)
- higher incidence in Western countries, related to low fibre diet

Pathogenesis

- risk factors:
 - low-fibre diet (increases gut transit time and intraluminal pressure)
 - muscle wall weakness from aging and illness (e.g. Ehler-Danlos, Marfan's)
 - possible genetic component
- high intraluminal pressures cause outpouching to occur at area of greatest weakness: most commonly at the site of penetrating vessels at antimesenteric tenia, therefore increased risk of hemorrhage

Clinical Features

- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic LLQ abdominal pain, bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications:
 - diverticulitis (15-20%)
 - bleeding (5-15%): PAINLESS rectal bleeding, 2/3 of massive lower GI bleeds

Treatment

- uncomplicated diverticulosis: high fibre, education
- diverticular bleed:
 - initially work up and treat as any lower GI bleed
 - if hemorrhage does not stop, resect involved region

Diverticulitis ("left sided appendicitis")

Definition

- infection or perforation of a diverticulum

Pathogenesis

- erosion of the wall by increased intraluminal pressure (or inspissated food particles) → microperforation/macroporforation → inflammation and focal necrosis
- usually mild inflammation with perforation walled off by pericolic fat
- sigmoid colon most often involved

Clinical Features

- severity ranges from mild inflammation to feculent peritonitis
- LLQ pain/tenderness, present for several days before admission
- alternating constipation and diarrhea, urinary symptoms (dysuria if inflammation adjacent to bladder)
- palpable mass if phlegmon or abscess, nausea, vomiting
- low-grade fever, mild leukocytosis
- occult or gross blood in stool less common
- generalized tenderness suggests macroperforation and peritonitis
- complications:
 - abscess – on physical exam may find palpable abdominal mass
 - fistula – colovesical (most common), coloenteric, colovaginal, colocutaneous
 - obstruction – due to scarring from repeated inflammation
 - macroperforation → peritonitis (feculent vs. purulent)
 - ♦ recurrent attacks RARELY lead to peritonitis

Investigations

- AXR, upright CXR:
 - localized diverticulitis (ileus, thickened wall, SBO, partial colonic obstruction)
 - free air may be seen in 30% with perforation and generalized peritonitis
- CT scan (optimal method of investigation) :
 - 97% sensitive, very useful for assessment of severity and prognosis
 - very helpful in localizing an abscess
- Hypaque® (water soluble) enema – SAFE (under low pressure):
 - saw-tooth pattern (colonic spasm)
 - may show site of perforation, abscess cavities or sinus tracts, fistulas
- barium enema: contraindicated during an acute attack:
 - risk of chemical peritonitis (because of perforation)
- sigmoidoscopy/colonoscopy:
 - not during an acute attack, only done on an elective basis
 - take biopsies to rule out other diagnoses (polyps, malignancy)

Treatment

- admit, NPO, fluid resuscitation, NG + suction, IV antibiotics covering *B. fragilis* (e.g. ciprofloxacin, metronidazole)
- indications for surgery:
 - unstable patient with peritonitis
 - Hinchey stage 2-4 (see Table 10)
 - after 1 attack if: (a) immunosuppressed, (b) abscess needing percutaneous drainage
 - consider after 2 or more attacks, recent trend is toward conservative management of recurrent mild/moderate attacks
- complications: generalized peritonitis, free air, abscess fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management
- surgical procedures:
 - Hartmann procedure: resection + colostomy and rectal stump → colostomy reversal in 3-6 months (see Figure 15)
 - resection + primary anastomosis (± pre-op bowel prep or on-table lavage): controversial (anastomosis of inflamed tissues = increased risk of anastomotic leakage)

Prognosis

- 13-30% recurrence after 1st attack, 30-50% after 2nd attack

Table 10. Hinchey Staging and Treatment for Diverticulitis

Hinchey Stage	Description	Acute treatment
1	Phlegmon / small pericolic abscess	Medical
2	Large abscess / fistula	Abscess drainage, resection ± primary anastomosis
3	Purulent peritonitis (ruptured abscess)	Hartmann procedure, sometimes primary anastomosis
4	Feculent peritonitis	Hartmann procedure

Figure 15. Hartmann Procedure

Colorectal Neoplasms

Colorectal Screening Guidelines

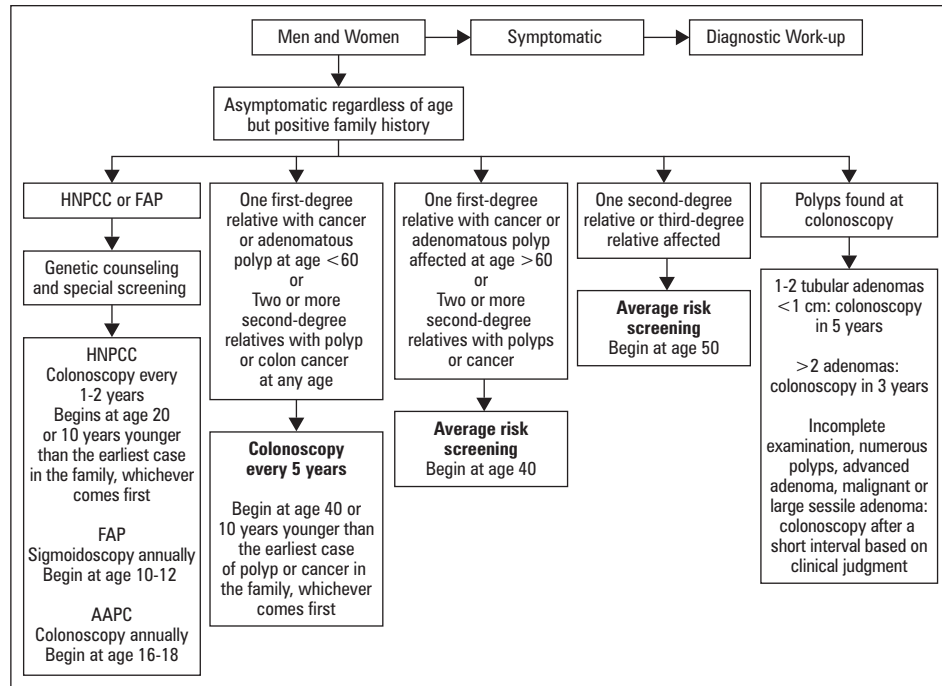

Figure 16. Approach to Higher Risk Screening

AAPC (attenuated adenomatous polyposis) FAP (familial adenomatous polyposis); HNPCC (hereditary nonpolyposis colorectal cancer); First degree relatives: parents, siblings, children; 2nd degree relatives: grandparents, aunts, uncles; 3rd degree relatives: great grandparents or cousins.

Colorectal Polyps

Definition

- polyp: small mucosal outgrowth into the lumen of the colon or rectum
- sessile (flat) or pedunculated (on a stalk) (see Figure 17)

Epidemiology

- 30% of population have polyps by age 50, 40% by age 60, 50% by age 70

Table 11. Characteristics of Tubular vs. Villous Polyps

	Tubular	Villous
Incidence	Common (60% to 80%)	Less common (10%)
Size	Small (<2 cm)	Large (usually >2 cm)
Attachment	Pedunculated	Sessile
Malignant Potential	Lower	Higher
Distribution	Even	Left-sided predominance

Clinical Features

- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, but may have rectal bleeding, change in bowel habit, mucous per rectum
- usually detected during routine endoscopy or familial/high risk screening

Pathology

- non-neoplastic:
 - hyperplastic – most common non-neoplastic polyp
 - pseudopolyps – inflammatory, associated with IBD, no malignant potential

Figure 17. Sessile and Pedunculated Polyps

- neoplastic:
 - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
 - ♦ malignant risk due to associated adenomas (large bowel)
 - ♦ low malignant potential → most spontaneously regress or autoamputate
 - adenomas – premalignant, often carcinoma in situ:
 - ♦ some may contain invasive carcinoma (“malignant polyp” – 3-9%): invasion into muscularis
 - ♦ malignant potential: villous > tubulovillous > tubular (see Table 11)

Investigations

- flexible sigmoidoscopy can reach 60% of polyps in men and 35% of polyps in women; if polyps detected, proceed to colonoscopy for examination of entire bowel and biopsy
- colonoscopy still the gold standard

Treatment

- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- surgical resection for those invading into muscularis (high risk of malignancy) and those too large to remove endoscopically
- follow-up endoscopy 1 year later, then every 3-5 years

Familial Colon Cancer Syndromes

FAMILIAL ADENOMATOUS POLYPOSIS (FAP)

Pathogenesis

- autosomal dominant (AD) inheritance, mutation in adenomatous polyposis coli (APC) gene on chromosome 5q

Clinical Features

- hundreds to thousands of colorectal adenomas usually by age 20 (by 40's in attenuated FAP)
- extracolonic manifestations:
 - carcinoma of duodenum, bile duct, pancreas, stomach, thyroid, adrenal, small bowel
 - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients
- virtually 100% lifetime risk of colon cancer (because of number of polyps)
- variants:
 - Gardner's syndrome: FAP + extraintestinal lesions (sebaceous cysts, osteomas, desmoid tumours)
 - Turcot's syndrome: FAP + CNS tumours (glioblastoma multiforme)

Investigations

- genetic testing (80-95% sensitive, 99-100% specific) (see sidebar)
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- if polyposis found: annual colonoscopy and consider surgery (see Figure 16)

Treatment

- surgery indicated by age 17-20
- total proctocolectomy with ileostomy OR total colectomy with ileorectal anastomosis
- doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

Referral Criteria for Genetic Screening for APC

- To confirm the diagnosis of FAP (in patients with ≥100 colorectal adenomas)
- To provide pre-symptomatic testing for individuals at risk for FAP (1st degree relatives who are ≥10 years old)
- To confirm the diagnosis of attenuated FAP (in patients with ≥20 colorectal adenomas)

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER (HNPCC)

Pathogenesis

- AD inheritance, mutation in a DNA mismatch repair gene resulting in genomic instability and subsequent mutations

Clinical Features

- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 years, lifetime risk 70-80% (M>F)
 - Lynch syndrome I: hereditary site-specific colon cancer
 - Lynch syndrome II: cancer family syndrome – high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis

- diagnosis is clinical – based on Amsterdam Criteria:
 - at least 3 relatives with colorectal cancer or HNPCC related CA
 - 2 or more generations involved, and 1 must be 1st degree relative of the other 2
 - 1 case must be diagnosed before 50 years old
 - FAP is excluded

Revised Bethesda Criteria – Refer for Genetic Screening for HNPCC

- Individuals with cancer in families that meet the Amsterdam Criteria
- Patients with two HNPCC-related cancers, including synchronous and metachronous colorectal cancer or associated extracolonic cancers (endometrial, ovarian, gastric, hepatobiliary, small bowel, or transitional cell carcinoma of the renal pelvis or ureter).
- Patients with colorectal cancer and a first degree relative with colorectal cancer and/or HNPCC-related extracolonic cancer and/or a colorectal adenoma with one of the cancers diagnosed before age 45, and the adenoma diagnosed before age 40.
- Patients with right-sided colorectal cancer having an undifferentiated pattern (solid/cirriiform) on histopathologic diagnosis before age 45.
- Patients with signet-ring cell type colorectal cancer diagnosed before age 45.
- Patients with adenomas diagnosed before age 40.

Screening for Colorectal Cancer (asymptomatic, no history of UC, polyps, or CRC)

- Average risk individuals, at age 50 (incl. those with <2 relatives with CRC) – recommendations are variable:
 - American Gastroenterology Society and American Cancer Society
 - Yearly fecal occult blood test (FOBT), flexible sigmoidoscopy q5y, colonoscopy q10y
 - Canadian Task Force on Preventative Health Care:
 - Yearly FOBT (“A” recommendation)
 - Sigmoidoscopy (“B” recommendation)
 - Whether to use one or both of FOBT or sigmoidoscopy (“C” recommendation)
 - Colonoscopy (“C” recommendation due to lack of good RCTs)
- Family Hx (>2 relatives with CRC/adenoma, one being a 1st degree relative):
 - Start screening 10 years prior to the age of the relative's with the earliest onset of carcinoma
- FAP genetic testing +ve:
 - Yearly sigmoidoscopy starting at puberty (“B” recommendation)
- HNPCC genetic testing +ve:
 - Yearly colonoscopy starting at age 20 (“B” recommendation)

Elderly persons who present with iron-deficiency anemia should be investigated for colon cancer.

Investigations

- genetic testing (80% sensitive) – colonoscopy mandatory even if negative
 - refer for genetic screening individuals who fulfill EITHER the Amsterdam Criteria (as above) OR the revised Bethesda Criteria (see sidebar)
- colonoscopy (starting age 20) annually
- surveillance for extracolonic lesions

Treatment

- total colectomy and ileorectal anastomosis with yearly proctoscopy

Colorectal Carcinoma (CRC)

Epidemiology

- 3rd most common cancer (after lung, prostate/breast), 2nd most common cause of cancer death

Risk Factors

- most patients have no specific risk factors
- FAP, HNPCC, family history of CRC
- adenomatous polyps (especially if >1 cm, villous, multiple)
- age >50 (dominant risk factor in sporadic cases), mean age is 70
- IBD (especially UC: risk is 1-2%/yr if UC >10 yrs)
- previous colorectal cancer (also gonadal or breast)
- diet (increased fat, red meat, decreased fibre) and smoking
- diabetes mellitus (insulin is a growth factor for colonic mucosal cells) and acromegaly

Screening Tools

- digital rectal exam (DRE): most common exam, but not recommended as a screening tool
- fecal occult blood test (FOBT):
 - proper test requires 3 samples of stool collected at 3 different times
 - recommended annually by the World Health Organization (WHO)
 - results in 16-33% reduction in mortality in RCTs
 - Minnesota Colon Cancer Study: RCT showed that annual FOBT can decrease mortality rate by 1/3 in patients 50-80 years old
- sigmoidoscopy:
 - can identify 30-60% of lesions
 - sigmoidoscopy + FOBT misses 24% of colonic neoplasms
- colonoscopy:
 - can remove or biopsy lesions during procedure
 - can identify proximal lesions missed by sigmoidoscopy
 - used as follow-up to other tests if lesions found
 - disadvantages: expensive, not always available, poor compliance, requires sedation, risk of perforation (0.2%)
- virtual colonoscopy (CT colonography): 91% sensitive, 17% false positive rate
- air contrast barium enema (ACBE): 50% sensitive for large (>1 cm) adenomas, 39% for polyps

Pathogenesis

- adenoma-carcinoma sequence; rarely arise *de novo*

Clinical Features (see Table 12)

- often asymptomatic
- hematochezia/melena, abdominal pain, change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, obstruction
- 3-5% have synchronous lesions
- spread:
 - direct extension, lymphatic, hematogenous (liver most common, lung, rarely bone and brain)
 - peritoneal seeding: ovary, Blumer's shelf (pelvic cul-de-sac)
 - intraluminal

Table 12. Clinical Presentation of CRC

	Right Colon	Left Colon	Rectum
Frequency	25%	35%	30%
Pathology	Exophytic lesions with occult bleeding	Annular, invasive lesions	Ulcerating
Symptoms	Weight loss, weakness, rarely obstruction	Constipation ± overflow (alternating bowel patterns), abdominal pain, decreased stool caliber, rectal bleeding	Obstruction, tenesmus, rectal bleeding
Signs	Fe-deficiency anemia, RLQ mass (10%)	BRBPR, LBO	Palpable mass on DRE, BRBPR

Investigations

- colonoscopy (best), look for synchronous lesions; alternative: air contrast barium enema ("apple core" lesion) + sigmoidoscopy
- if a patient is FOBT +ve, has microcytic anemia or has a change in bowel habits, do colonoscopy
- metastatic workup: CXR, abdominal CT/ultrasound
- bone scan, CT head only if lesions suspected
- labs: CBC, urinalysis, liver function tests, CEA (before surgery for baseline)
- staging (see Table 13 and sidebar)
- rectal cancer: pelvic MRI or endorectal ultrasound to determine T and N stage

Table 13. TNM Classification System for Staging of Colorectal Carcinoma

Primary Tumour (T)	Regional Lymph Nodes (N)	Distant Metastasis (M)
T0 No primary tumour found	N0 No regional node involvement	M0 No distant metastasis
Tis Carcinoma in situ	N1 Metastasis in 1-3 pericolic nodes	M1 Distant metastasis
T1 Invasion into submucosa	N2 Metastasis in 4 or more pericolic nodes	
T2 Invasion into muscularis propria	N3 Metastasis in any nodes along the course of named vascular trunks	
T3 Invasion through muscularis and into serosa		
T4 Invasion into adjacent structures or organs		

Treatment

- surgery (indicated in potentially curable or symptomatic cases – not usually in stage IV)
 - curative: wide resection of lesion (5 cm margins) with nodes and mesentery
 - palliative: if distant spread, then local control for hemorrhage or obstruction
 - 80% of recurrences occur within 2 years of resection
 - improved survival if metastasis consists of solitary hepatic mass that is resected
 - colectomy:
 - ♦ most patients get primary anastomosis [e.g. hemicolectomy, low anterior resection (LAR)] (see Figure 18)
 - ♦ if cancer is low in rectum, patient may require an abdominal perineal resection (APR) with a permanent end colostomy, especially if lesion involves the sphincter complex
 - ♦ complications: anastomotic leak or stricture, recurrent disease, pelvic abscess, enterocutaneous fistula
- radiotherapy and chemotherapy:
 - chemotherapy (5-FU based regimens): for patients with node-positive disease
 - radiation: for patients with node-positive or transmural rectal cancer (pre ± post-op), not effective as 1^o treatment of colon cancer
 - adjuvant therapy: chemotherapy (colon) and radiation (rectum)
 - palliative chemotherapy/radiation therapy for improvement in symptoms and survival
 - neoadjuvant chemoradiation for T3 or N1 rectal cancer

Case Finding for Colorectal Cancer (symptomatic or history of UC, polyps, or CRC)

- surveillance (when polyps are found): colonoscopy within 3 years after initial finding
- patients with past CRC: colonoscopy every 3-5 years, or more frequently
- IBD: some recommend colonoscopy every 1-2 years after 8 years of disease (especially UC)

Follow-Up

- intensive follow up improves overall survival in low risk patients
- currently there are no data suggesting optimal follow-up
- combination of periodic CT chest/abdo/pelvis, CEA and colonoscopy is recommended
- carcinogenic embryonic antigen (CEA): to monitor for initial response to treatment, and to assess for recurrence q3 months (not a screening test)

Staging for CRC

- I T1,2 N0M0
- II T3,4 N0M0
- III TxN+M0
- IV TxNxM1

Prognosis for CRC

Stage	5 yr survival %
T ₁ N ₀ M ₀	>90
T ₂ N ₀ M ₀	85
T ₃ N ₀ M ₀	70-80
T _x N ₁ M ₀	35-65
T _x N _x M ₁	5

Figure 18. Low Anterior Resection (LAR)

Combined-modality Treatment for Resectable Metastatic Colorectal Cancer to the Liver: Surgical Resection of Hepatic Metastases in Combination with Continuous Infusion of Chemotherapy – An Intergroup Study

J Clin Oncol 2002; 20(6):1499-505

Background: Metastatic spread of colorectal cancer commonly targets the liver, and long-term outcome studies of surgical resection of hepatic metastases have shown high rates of treatment failure. Arterial chemotherapy regimens targeted to the liver represent a promising adjuvant treatment to reduce recurrence rates.

Methods: Patients with 1-3 resectable liver metastases were randomized preoperatively to receive no further intervention (45 patients, control group) or postoperative floxuridine and fluorouracil (30 patients).

Results: 4-year recurrence-free survival rates were 25% for the control group and 46% for the chemotherapy group ($P=0.04$), with liver recurrence-free rates of 43% and 67% respectively ($P=0.03$).

Conclusions: Adjuvant intra-arterial and intravenous chemotherapy shows promise in preventing hepatic recurrence after surgical resection of colorectal cancer hepatic metastases.

APR removes distal sigmoid colon, rectum and anus, permanent end colostomy required.

LAR removes distal sigmoid and rectum with anastomosis of distal colon to anus.

Other Conditions of the Large Intestine

Angiodysplasia

Definition

- vascular anomaly: focal submucosal venous dilatation and tortuosity

Clinical Features

- most frequently in right colon of patients >60 years old
- bleeding typically intermittent (melena, anemia, guaiac positive stools)

Investigations

- endoscopy (cherry red spots, branching pattern from central vessel)
- angiography (slow filling/early emptying mesenteric vein, vascular tuft)
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

Treatment

- none if asymptomatic
- cautery, right hemicolectomy, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

Volvulus

Definition

- rotation of segment of bowel about its mesenteric axis
- sigmoid (70%), cecum (30%)

Risk Factors

- age (50% of patients >70 yrs: stretching/elongation of bowel with age is a predisposing factor)
- high fibre diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, institutionalized (less frequent evacuation of bowels)
- congenitally hypermobile cecum

Clinical Features

- symptoms due to bowel obstruction (GS23) or intestinal ischemia (GS27)

Investigations

- AXR: "omega", "bent inner-tube", "coffee-bean" signs (see sidebar)
- barium/gastrografin enema: "ace of spades" (or "bird's beak") appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT

Treatment

- initial supportive management with fluid, electrolyte resuscitation
- cecum:
 - nonsurgical
 - ♦ may attempt colonoscopic detorsion and decompression
 - surgical:
 - ♦ right colectomy + ileotransverse colonic anastomosis
- sigmoid:
 - nonsurgical
 - ♦ decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
 - ♦ subsequent elective surgery recommended (50-70% recurrence)
 - surgical: Hartmann procedure (if urgent)
 - ♦ indications: strangulation, perforation or unsuccessful endoscopic decompression

Cecal Volvulus

AXR: Central cleft of "coffee bean" sign points to RLQ.

Sigmoid Volvulus

AXR: Central cleft of "coffee bean" sign points to LLQ.

Barium enema: "ace of spades" or "bird's beak" sign.

Gastric Volvulus

Brochard's Triad

Epigastric distention

Failure to pass NG tube

Emesis followed by inability to vomit

Treatment: exploratory laparotomy to untwist and gastropexy

Fistula

Definition

- abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, entero-enteric)

Etiology

- foreign object erosion (e.g. gallstone, graft)
- infection, IBD (especially Crohn's), diverticular disease
- iatrogenic/surgery (e.g. postoperative anastomotic leak)
- congenital, trauma
- neoplastic

Investigations

- contrast radiography (fistulogram)
- sonogram
- CT scan
- measure amount of drainage from fistula

Treatment

- fluid resuscitation, manage electrolytes
- bowel rest – NPO
- drain any abscesses/control sepsis
- nutrition – elemental/low residue, TPN
- decrease secretion – octreotide/somatostatin/omeprazole
- skin care (for enterocutaneous fistula)
- surgical intervention – dependent upon etiology (for non-closing fistulas); uncertainty of diagnosis

Why Fistulae Stay Open

FRIENDO

- Foreign body
- Radiation
- Infection
- Epithelialization
- Neoplasm
- Distal obstruction (most common)
- Others: increased flow; steroids (may inhibit closure, usually will not maintain fistula)

Ostomies

Definition

- an opening of the GI tract onto the surface of the abdomen wall
- types (see Figure 19): colostomy vs. ileostomy, temporary vs. permanent, continent vs. incontinent, end vs. loop, ileoconduit
 - end (Brooke) ileostomy: for incontinent, continuous drainage in patients requiring total colectomy
 - Koch ileostomy: for continent, manual drainage – rarely used

Complications (10%)

- obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
- peri-ileostomy abscess and fistula
- skin irritation
- prolapse or retraction
- diarrhea (excessive output)

Colostomy/Ileostomy

- Connection of proximal limb of colon or ileum to abdominal wall skin

Mucous Fistula

- Connection of distal limb of colon to abdominal wall skin

Ileoconduit

- Connection of colon to ureter proximally + abdominal wall distally to drain urine

Figure 19. Ostomies

Anorectum

Hemorrhoids

Always rule out more serious causes (e.g. colon CA) in a person with hemorrhoids and rectal bleeding.

Figure 20. Hemorrhoids

Etiology

- vascular and connective tissue complexes form a plexus of dilated veins (cushion)
 - internal: superior hemorrhoidal veins, above dentate line, portal circulation
 - external: inferior hemorrhoidal veins, below dentate line, systemic circulation

Risk Factors

- increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal hypertension, heavy lifting

Clinical Features and Treatment

- internal hemorrhoids (see Figure 20):
 - engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
 - painless rectal bleeding, anemia, prolapse, mucus discharge, pruritus, burning pain, rectal fullness:
 - 1st degree:** bleed but do not prolapse through the anus
 - treatment: high fibre/bulk diet, sitz baths, steroid cream, pargoline (Anusol®), rubber band ligation, sclerotherapy, photocoagulation
 - 2nd degree:** prolapse with straining, spontaneous reduction
 - treatment: rubber band ligation, photocoagulation
 - 3rd degree:** prolapse requiring manual reduction
 - treatment: same as 2nd degree, but may require closed hemorrhoidectomy
 - 4th degree:** permanently prolapsed, cannot be manually reduced
 - treatment: closed hemorrhoidectomy
- external hemorrhoids (see Figure 20):
 - dilated venules usually mildly symptomatic
 - pain after bowel movement, associated with poor hygiene
 - medical treatment: dietary fibre, stool softeners, steroid cream (short course), pargoline (Anusol®), avoid prolonged straining
 - thrombosed hemorrhoids are very painful:
 - resolve within 2 weeks, may leave excess skin = perianal skin tag
 - treatment: consider surgical decompression within first 48 hours of thrombosis, otherwise medical treatment

Anal Fissures

Definition

- tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline, 10% anterior midline
- if off midline: consider IBD, STIs, TB, leukemia or anal carcinoma
- repetitive injury cycle after first tear:
 - sphincter spasm occurs preventing edges from healing and leads to further tearing
 - ischemia may ensue and contribute to chronicity

Etiology

- large, hard stools and irritant diarrheal stools
- tightening of anal canal secondary to nervousness/pain
- others: habitual use of cathartics, childbirth

Clinical Features

- acute fissure:
 - very painful bright red bleeding especially after bowel movement
 - treatment is conservative: stool softeners, sitz baths
- chronic fissure:
 - triad: fissure, sentinel skin tags, hypertrophied papillae
 - treatment:
 - stool softeners, bulking agents, sitz baths
 - topical nitroglycerin or nifedipine – increases local blood flow, promoting healing and relieves sphincter spasm
 - surgery (most effective) – lateral internal sphincterotomy; objective is to relieve sphincter spasm → increases blood flow and promotes healing; but 5% chance of fecal incontinence therefore not commonly done
 - alternative treatment:
 - botulinum toxin – inhibits release of acetylcholine (ACh), reducing sphincter spasm

Anorectal Abscess

Definition

- infection in one or more of the anal spaces (see Figure 21)
- usually bacterial infection of blocked anal gland at the dentate line
 - E. coli*, *Proteus*, *Streptococci*, *Staphylococci*, *Bacteroides*, anaerobes

Figure 21. Different Types of Perianal Abscesses

Clinical Features

- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (supralelevator) or horizontally (ischiorectal)
- tender perianal/rectal mass on exam

Treatment

- incision and drainage
 - curative in 50% of cases
 - 50% develop anorectal fistulas
- may require antibiotics if diabetic, heart murmur or cellulitis

Fistula-In-Ano

Definition

- connection between two epithelialized surfaces, one must be the rectum or anus
- an inflammatory tract with internal os at dentate line, external os on skin

Etiology

- see *Fistula*, GS37
- same perirectal process as anal abscess therefore usually associated with abscess
- other causes: post-op, trauma, anal fissure, malignancy, radiation proctitis

Clinical Features

- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract

Treatment

- identification:
 - internal opening:
 - Goodsall's rule (see Figure 22):
 - a fistula with an external opening anterior to the transverse anal line will have its internal opening at relatively the same position (e.g. external opening at 2 o'clock = internal opening at 2 o'clock) whereas all external openings posterior to the line will tend to have their internal openings in the midline
 - fistulous tract:
 - probing or fistulography under anesthesia

Figure 22. Goodsall's Rule

- surgery:
 - fistulotomy: unroof tract from external to internal opening, allow drainage
 - low lying fistula (does not involve external sphincter) → primary fistulotomy
 - high lying fistula (involves external sphincter) → staged fistulotomy with Seton suture placed through tract:
 - ♦ promotes drainage
 - ♦ promotes fibrosis and decreases incidence of incontinence
 - ♦ delineates anatomy
 - ♦ usually done to spare muscle cutting

Postoperative

- sitz baths, irrigation and packing to ensure healing proceeds from inside to outside

Complications

- recurrence
- rarely fecal incontinence

Pilonidal Disease

Definition

- acute abscess or chronic draining sinus in sacrococcygeal area

Epidemiology

- occurs most frequently in young men age 15-40 yrs

Etiology

- obstruction of the hair follicles in this area → formation of cysts, sinuses or abscesses

Clinical Features

- asymptomatic until acutely infected, then pain/tenderness, purulent discharge

Treatment

- acute abscess:
 - incision and drainage
 - wound packed open
 - 40% develop chronic pilonidal sinuses
- chronic disease:
 - pilonidal cystotomy
 - excision of sinus tract and cyst ± marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

Rectal Prolapse

Definition

- protrusion of full thickness of rectum through anus

Epidemiology

- extremes of ages – <5 years old and >5th decade
- 85% women

Etiology

- lengthened attachment of rectum secondary to constant straining
- 3 types:
 - I – false/mucosal: redundant rectal mucosa, radial furrows
 - II – incomplete: rectal intussusception without sliding hernia
 - III – true/complete (most common) (see Figure 23):
 - ♦ protrusion of entire rectal wall through anal orifice with herniation of pelvic peritoneum/cul-de-sac
 - ♦ circular furrows

Risk Factors

- gynecological surgery
- chronic neurologic/psychiatric disorders affecting motility

Clinical Features

- extrusion of mass with increased intra-abdominal pressure:
 - straining, coughing, laughing, Valsalva
- difficulty in bowel regulation:
 - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration and constant soiling
- may be associated with urinary incontinence or uterine prolapse

Figure 23. Rectal Prolapse (true vs. false)

Treatment

- Types I and II (false/mucosal/incomplete):
 - conservative – gentle replacement of prolapsed area, especially in children
 - hemorrhoidectomy with excision of redundant mucosa, mostly in adults
- Type III (true/complete):
 - conservative – reduce if possible
 - surgery – abdominal, perineal, transsacral approaches

Anal Neoplasms

ANAL CANAL**Squamous Cell Carcinoma (SCC) of Anal Canal (above dentate line)**

- most common tumour of anal canal (75%)
- anus prone to human papilloma virus (HPV) infection, therefore at risk for anal squamous intraepithelial lesions (ASIL)
 - high grade squamous intraepithelial lesion (HSIL) and low grade squamous intraepithelial lesion (LSIL) terminology used
- clinical features: anal pain, bleeding, mass, ulceration
- treatment: chemotherapy \pm radiation \pm surgery
- prognosis: 80% 5-year survival

Malignant Melanoma (MM) of Anal Canal

- 3rd most common site for primary MM after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- treatment: early radical surgery
- prognosis: <5% 5-year survival

ANAL MARGIN

- clinical features and treatment as for skin tumours elsewhere
- squamous and basal cell carcinoma, Bowen's disease (SCC in situ) and Paget's disease

Liver

Figure 24. Segmental Anatomy of Liver

Liver Cysts

SIMPLE CYSTS

- most common type of liver cyst, may have multiple simple cysts
- clinical features: usually asymptomatic, if large may present with pain or mass
- treatment: generally not required for simple cysts unless very large
- complications: intracystic hemorrhage (may be confused with complex cysts)

POLYCYSTIC LIVER DISEASE

- progressive condition where cysts replace much of the liver
- 50% associated with polycystic kidney disease
- treatment: if symptomatic treat by partial liver resection or by creating drainage for cysts

CHOLEDOCHAL CYSTS

- congenital malformations of pancreaticobiliary tree
- 4 types, most extreme form called Caroli's disease (multiple cystic dilations in intrahepatic ducts)
- clinical features: recurrent abdominal pain, intermittent jaundice, RUQ mass
- diagnosis: U/S, transhepatic cholangiography, LFTs
- treatment:
 - high risk of malignancy, current treatment is complete excision of cysts
 - extent of resection depends on type of cyst
 - liver transplant indicated if cyst involves intrahepatic bile ducts (Caroli's disease)
- complications of chronic choledochal cysts: biliary cirrhosis, portal hypertension, cholangiocarcinoma

HYDATID LIVER CYSTS (CYSTIC ECHINOCOCCOSIS)

- etiology:
 - infection with parasite *Echinococcus granulosus*
 - endemic to Southern Europe, Middle East, Australasia, South America
 - associated with exposure to dogs, sheep and cattle
- clinical features:
 - asymptomatic mass (most often) or chronic pain, hepatomegaly
 - rupture can cause biliary colic, jaundice or anaphylactic reaction
- investigations:
 - detection of anti-Echinococcus Ab (IgG) using ELISA or RIA
 - U/S, CT: presence of mass, often calcified
 - DO NOT perform needle biopsy as can cause seeding of abdominal cavity or anaphylaxis
- treatment:
 - medical: albendazole (anti-helminthic) – cure up to 30%
 - surgical (risk of spillage into abdomen):
 - ♦ conservative – open endocystectomy ± omentoplasty
 - ♦ radical – partial hepatectomy or total pericystectomy

CYSTADENOMA (PREMALIGNANT)/CYSTADENOCARCINOMA

- clinical features:
 - appear as complex cysts on imaging: internal septae, papillary projections, irregular lining
- all complex, multiloculated cysts (except echinococcal) should be excised because of malignancy risk

Liver Abscesses

Etiology

- types:
 - pyogenic (bacterial): most often Gram-negatives – *E. coli*, *Klebsiella*, *Proteus*
 - parasitic (amoebic): *Entamoeba histolytica*
 - fungal
- sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

Clinical Features

- fever, malaise, chills, anorexia, weight loss, abdominal pain, nausea
- RUQ tenderness, hepatomegaly, jaundice, dullness to percussion

Investigations

- leukocytosis, anemia, elevated liver enzymes, hemagglutination titres for *Entamoeba* antibodies
- U/S, CXR (right basilar atelectasis/effusion), CT

Treatment

- treat underlying cause
- surgical or percutaneous drainage and IV antibiotics

Prognosis

- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, malnutrition

Neoplasms

BENIGN LIVER NEOPLASMS**Hemangioma (cavernous)**

- pathogenesis: most common benign hepatic tumour; results from malformation of angioblastic fetal tissue
- risk factors: F:M = 6:1, steroid therapy, estrogen (exogenous, pregnancy)
- clinical features:
 - usually small and asymptomatic, larger tumours may produce pain or compress nearby structures
 - shock if ruptured (very rare)

- investigations:
 - contrast CT (well-demarcated hypodense mass with peripheral enhancement and delayed venous emptying), U/S (homogenous hyperechoic mass), arteriography (rarely used; "cotton wool" appearance), RBC scan
 - biopsy may result in hemorrhage
- treatment:
 - usually none unless tumour bleeds or is symptomatic, then excision by lobectomy or enucleation

Adenoma

- definition: benign glandular epithelial tumour
- risk factors: female, age 30-50, estrogen (OCP, pregnancy)
- clinical features: asymptomatic, 25% present with RUQ pain or mass
- investigations: CT (well-demarcated masses, often heterogenous, isodense on non-contrast CT, peripheral enhancement/isodense/hypodense on contrast CT), U/S (variable appearance; usually hyperechoic), biopsy
- treatment:
 - stop anabolic steroids or OCP
 - excise, especially if large (>5 cm), due to risk of malignancy and spontaneous rupture/hemorrhage

Focal Nodular Hyperplasia

- pathogenesis: thought to be due to local ischemia and tissue regeneration
- risk factors: female, middle age
- clinical features: asymptomatic, rarely grows or bleeds, no malignant potential
- investigations: central stellate scar on CT scan, technetium-99 scan is helpful
- treatment: may be difficult to distinguish from adenoma (malignant potential) → often resected

MALIGNANT LIVER NEOPLASMS

Primary

- usually hepatocellular carcinoma (HCC)/hepatoma
- others include angiosarcoma, hepatoblastoma, hemangioendothelioma
- epidemiology: uncommon in North America, but represents 20-25% of all carcinomas in Asia and Africa
- risk factors:
 - chronic liver inflammation: chronic hepatitis B (inherently oncogenic) and C, cirrhosis (especially macronodular), hemochromatosis, α_1 -anti-trypsin
 - meds: OCPs (3x increased risk), steroids
 - smoking, alcohol
 - chemical carcinogens (aflatoxin, vinyl chloride – associated with angiosarcoma)
- clinical features:
 - RUQ discomfort, right shoulder pain
 - jaundice, weakness, weight loss, \pm fever
 - hepatomegaly, bruit, rub
 - ascites with blood (sudden intra-abdominal hemorrhage)
 - paraneoplastic syndromes – e.g. Cushing's syndrome, hypoglycemia
 - metastasis: lung, bone, brain, peritoneal seeding
- investigations:
 - elevated ALP, bilirubin, and α -fetoprotein (80% of patients)
 - U/S (poorly-defined margins with internal echos), triphasic CT (enhancement on arterial phase and washout on portal venous phase), MRI, CT or MRI angiography
 - biopsy
- treatment:
 - cirrhosis is a *relative* contraindication to tumour resection due to decreased hepatic reserve
 - surgical: resection (10% of patients have resectable tumours)
 - liver transplant (if cirrhosis plus solitary nodule <5 cm, or less than 3 nodules each <3 cm (Milan criteria); generally not with extrahepatic disease or vascular invasion)
 - non-surgical: radiofrequency ablation, percutaneous ethanol injection, transcatheter arterial chemoembolization (TACE), chemotherapy (limited efficacy)
- prognosis:
 - 70% have metastases to nodes and lung
 - survival without treatment: 3 months
 - 5 year survival: all patients – 5%; patients undergoing complete resection – 11-40%

Secondary

- most common hepatic malignancy
- etiology:
 - GI (most common), lung, breast, pancreas, ovary, uterus, kidney, gallbladder, prostate
- treatment:
 - hepatic resection if control of primary is possible, no extrahepatic or extrapulmonary metastases and if possibility of "curative" resection
 - possible chemotherapy
- prognosis: 30-40% 5-year survival with a "curative" resection; prognosis same if metastases are multilobar compared with confined to one lobe

Differential Diagnosis of Metastatic Liver Mass

Some GU Cancers Produce Bumpy Lumps:
 Stomach
 Genitourinary cancers – kidney, ovary, uterus
 Colon
 Pancreas
 Breast
 Lung

Child-Turcotte-Pugh Score (Prognosis of Chronic Liver Disease/Cirrhosis, Including Postoperatively)

	1 Point	2 Points	3 Points
Albumin	>35 >3.5 g/dL	30-35 3.0-3.5	<28 <3.0
Ascites	Absent	Easily controlled	Poorly controlled
Bilirubin	<34 umol/L <2.0 mg/dL	34-51 2.0-3.0	>51 >3.0
Coagulation (INR)	<1.7 PT 0-4s	1.7-2.3 4-6	>2.3 >6
Hepatic encephalopathy	None	Minimal (Grade I-II)	Advanced (Grade III-IV)

Points	Class	One Year Survival	Two Year Survival
5-6	A	100%	85%
7-9	B	81%	57%
10-15	C	45%	35%

Liver Transplantation

Table 14. Conditions Leading to Transplantation

Parenchymal Disease	Cholestatic Disease	Inborn Errors	Tumours
Chronic hepatitis B or C*	Biliary atresia**	α_1 -anti-trypsin deficiency	Hepatoma
Alcoholic cirrhosis	Primary biliary cirrhosis	Wilson's disease	
Acute liver failure	Sclerosing cholangitis	Hemochromatosis	
Budd-Chiari syndrome			
Congenital hepatic fibrosis			
Cystic fibrosis (CF)			

*leading cause in adults; ** leading cause in children

Clinical Indications

- early referral for transplant should be considered for all patients with progressive liver disease not responding to medical therapy, especially decompensated cirrhosis, unresectable primary liver cancers and fulminant hepatic failure
- end-stage liver disease with life expectancy <1 year and if no other therapy is appropriate
- progressive jaundice, refractory ascites, spontaneous hepatic encephalopathy, recurrent sepsis, fulminant hepatic failure
- recurrent variceal hemorrhage, coagulopathy, severe fatigue

Criteria for Transplantation

- Model for End-Stage Liver Disease (MELD): considers probability of death within 3 months if patient does not receive transplant; based on creatinine, bilirubin, INR
- Child-Turcotte-Pugh Score: patient must have ≥ 7 points (Class B)

Contraindications

- sepsis, HIV positive status
- active alcohol/substance abuse
- extrahepatic metastasis
- advanced cardiopulmonary disease

Post-op Complications

- primary non-function (graft failure) – urgent re-transplantation is indicated
- acute and chronic rejection, ischemia-reperfusion injury
- vascular – hepatic artery or portal vein thrombosis, IVC obstruction
- biliary complications – fever, increasing bilirubin and ALP
- recurrence of hepatitis B – prophylactic medical therapy is usually effective in preventing recurrence in graft; hepatitis C anti-recurrence therapy is less effective but recurrence can be controlled medically

Prognosis

- patient survival at 1 year – 85%
- graft survival at 1 year – 60-70%, at 5 years – 40-50%

Biliary Tract

Cholelithiasis

Definition

- the formation of gallstones (see Figure 25)

Pathogenesis

- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excessive hepatic cholesterol secretion \rightarrow bile salts and lecithin are “overloaded” \rightarrow supersaturated cholesterol can precipitate and form gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

Risk Factors

- cholesterol stones:
 - obesity, age <50
 - estrogens: female, multiparity, OCPs
 - ethnicity: First Nations heritage > Caucasian > Black
 - terminal ileal resection or disease (e.g. Crohn's disease)
 - impaired gallbladder emptying: starvation, TPN, DM type I
 - rapid weight loss: rapid cholesterol mobilization and biliary stasis
- pigment stones (contain calcium bilirubinate):
 - cirrhosis
 - chronic hemolysis
 - biliary stasis (strictures, dilation, biliary infection)

Summary of Biliary Tract Conditions

Gall Bladder	Asymptomatic Pain Only	Infection + Pain
Cholelithiasis	✓ (majority)	
Biliary Colic		✓
Cholecystitis		✓
Common Bile Duct	Asymptomatic Pain Only	Infection + Pain
Cholelithiasis	✓ (majority)	✓
Cholangitis		✓ (majority)

Risk factors for cholesterol stones
“4F’s”: Fat, Female, Fertile, Forties

Figure 25. Gallstones

Clinical Features

- asymptomatic (80%):
 - most do NOT require treatment
 - consider cholecystectomy if: porcelain (calcified) gallbladder (25% risk of malignancy), sickle cell disease, pediatric patient, having bariatric surgery, diabetes, immunosuppression
- biliary colic (10-25%)
- cholecystitis
- choledocholithiasis (8-15%)
- cholangitis
- gallstone pancreatitis (see *Acute Pancreatitis*, GS49)
- gallstone ileus

Investigations

- U/S – diagnostic procedure of choice:
 - image for signs of inflammation, obstruction, localization of stones
- ERCP (endoscopic retrograde cholangiopancreatography):
 - visualization of upper GI tract, ampullary region, biliary and pancreatic ducts
 - method for treatment of CBD stones in periampullary region
 - complications: traumatic pancreatitis (1-2%), pancreatic or biliary sepsis
- MRCP (magnetic resonance cholangiopancreatography):
 - same information gained as ERCP but non-invasive
 - cannot be used for therapeutic purposes
- PTC (percutaneous transhepatic cholangiography):
 - injection of contrast via needle passed through hepatic parenchyma
 - useful for proximal bile duct lesions or when ERCP fails or not available
 - requires prophylactic antibiotics
 - contraindications: coagulopathy, ascites, peri/intrahepatic sepsis, disease of right lower lung or pleura
 - complications: bile peritonitis, chylothorax, pneumothorax, sepsis, hemobilia
- HIDA scan (hepatobiliary imino-diacetic acid scan):
 - used less commonly
 - radioisotope technetium-99 injected into a vein is excreted in high concentrations into bile, allowing visualization of the biliary tree
 - does not visualize stones; diagnosis by seeing occluded cystic duct or CBD

U/S is diagnostic procedure of choice for imaging the biliary tree.

Biliary Colic

Pathogenesis

- gallstone transiently impacted in cystic duct, no infection

Clinical Features

- steady pain in epigastrium or RUQ for minutes to hours, crescendo-decrescendo pattern
- frequently occurs at night or after fatty meal
- can radiate to right shoulder or scapula
- patients often restless
- no peritoneal findings, no systemic signs

Biliary colic is a constant pain not colicky.

Does this Patient have Acute Cholecystitis?

JAMA 2003; 289:80-86

Study: Looking at the ability of the clinical exam and basic laboratory findings to determine which patients need diagnostic imaging techniques to diagnose acute cholecystitis.

Selection criteria: Studies from 1966-2002 which evaluated the history, physical and basic laboratory tests in adult patients with abdominal pain or suspected acute cholecystitis. These studies had to have a control group with no diagnosis of acute cholecystitis. Acute cholecystitis was diagnosed through several different modalities (e.g. surgery, pathologic examination, etc.). This included 17 articles.

Results: No clinical or laboratory finding was sufficient to rule in or rule out the diagnosis of acute cholecystitis. The best finding for ruling in was positive Murphy's sign (LR+ = 2.8 95% CI 0.8-86) and the best test for ruling out was absence of right upper quadrant tenderness (LR - 0.4 95% CI 0.2-1.1), but neither of these findings were statistically significant. No study looked at the combination of clinical and laboratory findings.

Conclusion: No single clinical findings or laboratory test can rule in or rule out the diagnosis of acute cholecystitis. It is through a combination of clinical findings and diagnostic imaging that the diagnosis of acute cholecystitis is made in patients presenting with abdominal pain.

Laparoscopic vs. Open Cholecystectomy**Laparoscopic Cholecystectomy**

Shorter operating time
Shorter length of stay
Shorter sick leave
Shorter time to return to daily activities
Less postoperative pain*
Decreased use of postoperative analgesia*
Decreased reduction in pulmonary function*
Fewer pulmonary complications
Decreased acute phase response
Less impairment in intestinal motility*

Open Cholecystectomy

Lower conversion rates to open surgery (for mini-laparotomies)

***NOTE:**

Postoperative pain = measured on visual analog scale
Analgesic use = patient-controlled morphine consumption
Pulmonary function = O₂ consumption, spirometric parameters, arterial blood gases, and acid-base balance
Intestinal motility = auscultating intestinal peristalsis, abdominal circumference measurement, and time interval to restitution of defecation

Acute cholecystitis is treated with antibiotics and early cholecystectomy

Biliary colic is treated with analgesia and elective cholecystectomy

Investigations

- normal blood work: CBC, electrolytes, LFTs, bilirubin, amylase
- U/S shows cholelithiasis, may show stone in cystic duct

Treatment

- analgesia, rehydration during colic episode
- elective cholecystectomy (95% success):
 - complications: CBD injury (0.3-0.5%), hollow viscus injury, bile peritonitis, vessel injury
 - laparoscopic cholecystectomy is the standard of care
 - risk of open cholecystectomy higher in emergency situations

Acute Cholecystitis**Pathogenesis**

- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see *Acalculous Cholecystitis*, GS47)

Clinical Features

- often have history of biliary colic
- severe constant (hours to days) epigastric or RUQ pain, anorexia, nausea, vomiting, low grade fever (<38.5°C)
- focal peritoneal findings: Murphy's sign, palpable, tender gallbladder (in 33%)
- Boas' sign: right subscapular pain

Investigation

- bloodwork: elevated WBC and left shift, mildly elevated bilirubin, AST, ALT, ALP
- U/S:
 - 98% sensitive, consider HIDA scan if U/S negative
 - features on U/S (5 signs):
 - ♦ distended gallbladder
 - ♦ pericholecystic fluid
 - ♦ stone in cystic duct
 - ♦ thickened gallbladder wall (>3 mm)
 - ♦ sonographic Murphy's Sign – maximum tenderness on inspiration when probe over gallbladder

Complications

- gallbladder mucocele (hydrops) – long term cystic duct obstruction results in mucous accumulation in gallbladder (clear fluid)
- gangrene, perforation – result in abscess formation or peritonitis
- empyema of gallbladder – suppurative cholecystitis, pus in gallbladder + sick patient
- cholecystoenteric fistula, from repeated attacks of cholecystitis, can lead to gallstone ileus
- emphysematous cholecystitis – bacterial gas present in gallbladder lumen, wall or pericholecystic space (risk in diabetic patient)
- Mirizzi's syndrome – extra-luminal compression of CBD/CHD due to large stone in cystic duct

Treatment

- admit, hydrate, NPO, NG tube (if persistent vomiting from associated ileus), analgesics once diagnosis is made
- antibiotics:
 - *E. coli*, *Klebsiella*, *Enterococcus* and *Clostridium* account for >80% of infections
 - ampicillin + gentamicin OR Cipro® + Flagyl®
- cholecystectomy:
 - early (within 72 hrs) vs. delayed (after 6 weeks)
 - ♦ equal morbidity and mortality
 - ♦ early cholecystectomy preferred: shorter hospitalization and recovery time
 - ♦ emergent OR indicated if high risk, e.g. emphysematous, diabetic patient
 - laparoscopic is standard of care (convert to open for complications or difficult case)
 - ♦ laparoscopic: reduced risk of wound infections, shorter hospital stay, reduced post-op pain, increased risk of bile duct injury
- intra-operative cholangiography (IOC):
 - indications: clarify bile duct anatomy, obstructive jaundice, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), single faceted stone in gallbladder, bilirubin >137 µmol/L
- percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated

Acalculous Cholecystitis

Definition

- acute or chronic cholecystitis in the absence of stones

Pathogenesis

- typically due to gallbladder stasis → sludge forms in gallbladder

Risk Factors

- DM, immunosuppression, ICU admission, trauma patient, TPN, sepsis

Clinical Features

- see *Acute Cholecystitis*, GS46
- occurs in 20% of cases of acute cholecystitis

Investigations

- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see *Acute Cholecystitis*, GS46)
- CT or HIDA scan

Treatment

- cholecystectomy
- if patient unstable → cholecystostomy

Choledocholithiasis

Definition

- stones in common bile duct (CBD)

Clinical Features

- 50% asymptomatic
- often have history of biliary colic
- tenderness in RUQ or epigastrium
- acholic stool, dark urine, fluctuating jaundice
- primary vs. secondary stones:
 - primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst)
 - secondary: formed in gallbladder (85% of cases in U.S.)

Investigations

- CBC: usually normal; leukocytosis suggests cholangitis
- LFTs: increased bilirubin, ALP
- amylase/lipase: to rule out gallstone pancreatitis
- U/S: intra/extra-hepatic duct dilatation
- ERCP, PTC
- MRCP (90% sensitive, almost 100% specific, not therapeutic)

Complications

- cholangitis, pancreatitis, biliary stricture and biliary cirrhosis

Treatment

- if no evidence of cholangitis: treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients

Acute Cholangitis

Pathogenesis

- obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration and biliary sepsis

Etiology

- choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), biliary stent
- organisms: *E. coli*, *Klebsiella*, *Pseudomonas*, *Enterococcus*, *B. fragilis*, *Proteus*

Clinical Features

- Charcot's triad – fever, RUQ pain, jaundice
- Reynolds' pentad – fever, RUQ pain, jaundice, shock, confusion
- may have nausea, vomiting, abdominal distention, ileus, acholic stools, tea-coloured urine

Investigations

- CBC: elevated WBC + left shift
- may have positive blood cultures
- LFTs: obstructive picture (elevated ALP and conjugated bilirubin, mild increase in AST, ALT)
- amylase/lipase: rule out pancreatitis
- U/S: intra/extra-hepatic duct dilatation

Charcot's Triad
Fever, RUQ pain, jaundice.

Reynolds' Pentad
Fever, RUQ pain, jaundice, shock, confusion.

**Common Bacteria in Biliary Tract****KEEPS**

Klebsiella
Enterococcus
E. Coli, *Enterobacter*
Proteus, *Pseudomonas*
Serratia

Treatment

- initial: NPO, fluid and electrolyte resuscitation, \pm NG tube, IV antibiotics
- decompression:
 - ERCP + sphincterotomy – diagnostic and therapeutic
 - PTC with catheter drainage – if ERCP not available or unsuccessful
 - laparotomy with CBD exploration and T-tube placement if above fails
- all patients should also have a cholecystectomy, unless contraindicated

Prognosis

- suppurative cholangitis – mortality rate: 50%

Gallstone Ileus

Pathogenesis

- repeated inflammation causing a cholecystoenteric fistula (usually duodenal) \rightarrow large gallstone enters the gut and impacts at or near the ileocecal valve, causing a true bowel obstruction (note: ileus is a misnomer in this context)

Clinical Features

- crampy abdominal pain, nausea, vomiting (see *Bowel Obstruction*, GS23)

Investigations

- AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, air in biliary tree (40%)
- CT: biliary tract air, obstruction, gallstone in intestine

Treatment

- fluid resuscitation, NG decompression
- surgery: enterotomy and removal of stone, inspect small and large bowel for additional proximal stones
- fistula usually closes spontaneously
- elective cholecystectomy after recovery if patient experiences gallbladder symptoms

Carcinoma of the Gallbladder

Risk Factors

- chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder

Clinical Features

- majority are adenocarcinoma
- may be incidental finding on elective cholecystectomy (~1% of elective cholecystectomies)
- many patients are asymptomatic until late
- local: vague RUQ pain, \pm palpable RUQ mass
- systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, weight loss, malaise, anorexia
- early local extension to liver, may extend to stomach, duodenum
- early metastasis common to liver, lung, bone

Investigations

- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, fixed mass
- endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as polyps, good for staging, allows sampling of bile for cytology
- abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, distant mets

Treatment

- if carcinoma of the gallbladder is suspected preoperatively, an open cholecystectomy should be done to avoid tumour seeding of trocar sites
- confined to mucosa (rare) – cholecystectomy
- beyond mucosa – cholecystectomy, en bloc wedge resection of 3-5 cm underlying liver, dissection of hepatoduodenal lymph nodes

Prognosis

- poor 5-year survival (10%) as gallbladder carcinoma is often detected late

**Bouveret's Syndrome**

Gastric outlet/duodenal obstruction caused by a large gallstone passing through a cholecystogastric or cholecystoduodenal fistula.

Cholangiocarcinoma

Definition

- malignancy of extra intrahepatic bile ducts

Risk Factors

- age 50-70, gallstones, ulcerative colitis, primary sclerosing cholangitis, choledochal cyst, *Clonorchis sinensis* infection (liver fluke)

Clinical Features

- majority are adenocarcinoma
- gradual signs of biliary obstruction: jaundice, pruritis, dark urine, pale stool
- anorexia, weight loss, RUQ pain, Courvoisier's sign (if CBD obstructed), hepatomegaly
- early metastases are uncommon, but commonly tumour grows into portal vein or hepatic artery
- Klatskin tumour – cholangiocarcinoma located at bifurcation of common hepatic duct

Investigations

- LFTs show obstructive picture
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup

Treatment

- generally palliative
- if resectable: biliary drainage and wide excision margin
 - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
 - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
 - lower third lesions: Whipple procedure
- unresectable lesions: stent or choledochojejunostomy (surgical bypass)

Prognosis

- radiotherapy useful for additional palliation, chemotherapy may be helpful
- the more proximal to the liver, the worse the prognosis
- overall 5-year survival – 15%

Obstructive jaundice is the most common presenting symptom for cholangiocarcinoma.

Courvoisier's Sign

Palpable, nontender distended gallbladder due to CBD obstruction. Present in 33% of patients with pancreatic carcinoma. The distended gallbladder could not be due to acute cholecystitis or stone disease because the gallbladder would actually be scarred and smaller, not larger.

Pancreas

Acute Pancreatitis

- see Gastroenterology, G48

GALLSTONE PANCREATITIS

Pathogenesis

- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

Clinical Features (pancreatitis of any etiology)

- pain (epigastric pain radiating to back), nausea, vomiting, ileus, peritoneal signs, jaundice, fever
- Ingelfinger's sign: pain worse when supine, better when sitting forward
- rarely may have coexistent cholangitis or pancreatic necrosis
- Ranson's criteria for determining prognosis of acute pancreatitis (see sidebar)

Investigations

- high amylase (higher than alcoholic pancreatitis), lipase, high liver enzymes, leukocytosis
- U/S may show multiple stones (may have passed spontaneously), edematous pancreas
- CXR, AXR, CT (if severe to evaluate for complications)

Treatment

- supportive
- NPO, hydration, analgesia and antibiotics for severe cases of necrotizing pancreatitis or signs of sepsis
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission after acute attack has subsided (25-60% recurrence if no surgery)

Ranson's Criteria

A. At admission

1. Age >55 years
2. WBC >16 x 10⁹/L
3. Glucose >11 mmol/L
4. LDH ≥350 IU/L
5. AST >250 IU/L

B. During initial 48 hours

1. Hct drop >10%
2. BUN rise >1.8 mmol/L
3. Arterial PO₂ <60 mmHg
4. Base deficit >4 mmol/L
5. Calcium <2 mmol/L
6. Fluid sequestration >6 L

C. Interpretation

- ≥2 – difficult course
- ≥3 – high mortality

- may need urgent ERCP + sphincterotomy if failure of conservative management (no benefit has been shown for early ERCP + sphincterotomy if no obstructive jaundice is present)
- surgical indications in acute pancreatitis (rare):
 - debridement and drain placement for necrotizing pancreatitis if refractory to medical management, if septic or in ICU without other sources of sepsis

Complications

- pseudocyst (collection of pancreatic secretions >4 weeks old surrounded by a defined wall of granulation tissue)
- abscess/infection, necrosis
- splenic/mesenteric/portal vessel thrombosis or rupture
- pancreatic ascites/pancreatic pleural fluid effusion
- diabetes
- ARDS/sepsis/multiorgan failure
- coagulopathy/DIC
- encephalopathy
- severe hypocalcemia

Chronic Pancreatitis

- see also Gastroenterology, G50

Surgical Treatment

- treatment is generally medical
- indications for surgery:
 - failure of medical treatment
 - debilitating abdominal pain
 - pseudocyst complications: persistence, hemorrhage, infection, rupture
 - CBD obstruction (e.g. strictures), duodenal obstruction
 - pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
 - rule out pancreatic cancer
 - anatomical abnormality causing recurrent pancreatitis
- pre-op CT and/or ERCP are mandatory to delineate anatomy
- surgical options:
 - drainage procedures – only effective if ductal system is dilated
 - ♦ endoscopic duct decompression
 - ♦ Puestow procedure (longitudinal pancreatojejunostomy) – improves pain in 80% of patients
 - pancreatectomy – best option in absence of dilated duct
 - ♦ proximal disease – Whipple procedure (pancreatoduodenectomy): pain relief in 80%
 - ♦ distal disease – distal pancreatectomy ± Roux-en-Y pancreatojejunostomy
 - ♦ total pancreatectomy – refractory disease
 - nerve ablation:
 - ♦ celiac plexus block – lasting benefit in 30% patients, much less invasive
- pseudocyst (most resolve spontaneously with pancreatic rest):
 - cyst wall must be mature (4-6 weeks)
 - internal drainage (preferred): Roux-en-Y cyst-jejunostomy or cyst-gastrostomy
 - external drainage: may require second operation to treat pancreatic fistula
 - consider biopsy of cyst wall to rule out cystadenocarcinoma

The hallmark of chronic pancreatitis is epigastric pain radiating to the back.

Pancreatic Cancer

Epidemiology

- fourth most common cause of cancer-related mortality in both men and women in Canada in 2007 (Canadian Cancer Society)
- male:female = 1.7:1, average age: 50-70

Risk Factors

- increased age
- smoking – 2-5x increased risk, most clearly established risk factor
- high fat/low fibre diets, heavy alcohol use
- DM, chronic pancreatitis
- chemicals: betanaphthylamine, benzidine
- African descent

Clinical Features

- head of the pancreas (70%):
 - weight loss, obstructive jaundice, vague constant mid-epigastric pain (often worse at night, may radiate to back)
 - painless jaundice (occurs more often with peri-ampullary), Courvoisier's sign (see sidebar GS49)
 - palpable tumour mass → generally incurable
- body or tail of pancreas (30%):
 - tends to present later and usually inoperable
 - weight loss, vague mid-epigastric pain
 - <10% jaundiced
 - sudden onset diabetes

Vague abdominal pain with weight loss ± jaundice in a patient over 50 years old is pancreatic cancer until proven otherwise.

Investigations

- serum chemistry non-specific: elevated ALP and bilirubin >300 µmol/L
- U/S, contrast CT (also evaluates metastasis and resectability), ERCP

Pathology

- ductal adenocarcinoma – most common type (75-80%); exocrine pancreas
- intraductal papillary mucinous neoplasm (IPMN)
- other: mucinous cystic neoplasm (MCN), acinar cell carcinoma, islet-cell (insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma)

Treatment

- resectable (20% of pancreatic cancer)
 - no involvement of liver, peritoneum or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
 - Whipple procedure (pancreatoduodenectomy) for cure – 5% mortality (Figure 26)
 - distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
- non-resectable (palliative → relieve pain, obstruction)
 - most body/tail tumours are not resectable (due to late presentation)
 - relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochoenterostomy + gastroenterostomy)
 - chemotherapy (gemcitabine), radiotherapy – only slightly increase survival

Whipple Procedure (Pancreatoduodenectomy)

1. Removal

Choledochoectomy
Cholecystectomy
Duodenectomy
Distal pancreatectomy
± Distal gastrectomy

2. New Connections

Hepaticojejunostomy (connect common hepatic duct to jejunum post cholecystectomy)
Pancreaticojejunostomy (connect distal pancreas remnant)
Gastrojejunostomy

Prognosis

- most important prognostic indicators are lymph node status, size >3 cm, perineural invasion (invasion of tumour into microscopic nerves of pancreas)
- overall 5 year survival is 1%
- average survival – 6 months if unresected, 12-18 months with curative resection

Figure 26. Schematic of Whipple Resection, Showing the Resected Components

Spleen

Splenic Trauma

- typically from blunt trauma (especially in people with splenomegaly)
- most common intra-abdominal organ injury in blunt trauma
- may have Kehr's sign: left shoulder pain due to diaphragmatic irritation from splenic rupture

Treatment

- in stable patients – extended bed rest with serial hematocrit levels, close monitoring
- hemostatic control
- splenic artery embolization
- splenorrhaphy (suture of spleen) – if patient hemodynamically stable, patient has stopped bleeding and laceration does not involve hilum
- partial splenectomy
- total splenectomy if patient unstable or high-grade injury

Splenectomy

Indications

- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenia purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenia purpura (TTP), non-Hodgkin's lymphoma, primary splenic tumour (rare)
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIg

Complications

- short-term:
 - atelectasis of left lower lung, bleeding, infection
 - injury to surrounding structures (e.g. gastric wall, tail of pancreas)
 - post-op thrombocytosis, leukocytosis
 - subphrenic abscess
- long-term:
 - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients
 - 50% mortality
 - pre-op prophylaxis with vaccinations (pneumococcal, *H. influenzae* and meningococcus)
 - liberal use of penicillin especially in children <6 years old

Breast

Levels of Axillary Lymph Nodes
Level I: lateral to pectoralis minor
Level II: deep to pectoralis minor
Level III: medial to pectoralis minor
 (Higher level = worse prognosis)

Figure 27. Anatomy of the Breast

Benign Breast Lesions

NON-PROLIFERATIVE LESIONS

- aka fibrocystic change, chronic cystic mastitis, mammary dysplasia
- benign breast condition characterized by fibrous and cystic changes in the breast
- no increased risk of breast cancer
- age 30 to menopause (and after if HRT used)
- clinical features:
 - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, nipple discharge (straw-like, brown or green)
- treatment:
 - evaluation of breast mass and reassurance
 - if >40 years old: mammography every 3 years
 - no strong evidence for avoidance of xanthine-containing products (coffee, tea, chocolate, cola)
 - analgesia (ibuprofen, ASA)
 - for severe symptoms: OCP, danazol, bromocriptine

DDx for Breast Mass

- Breast Ca
- Fibrocystic changes
- Fibroadenoma
- Fat necrosis
- Papilloma/papillomatosis
- Galactocele
- Duct ectasia
- Ductal/lobular hyperplasia
- Sclerosing adenosis
- Lipoma
- Neurofibroma
- Granulomatous mastitis (e.g. TB, Wegener's, sarcoidosis)
- Abscess
- Silicone implant

PROLIFERATIVE LESIONS – No Atypia

Fibroadenoma

- most common benign breast tumour in women under age 30
- risk of subsequent breast cancer is increased only if fibroadenoma is complex, there is adjacent atypia or a strong family history of breast cancer
- clinical features:
 - nodules: smooth, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone dependent
 - unlike cysts, needle aspiration yields no fluid
- investigations:
 - core or excisional biopsy required
 - ultrasound and FNA alone cannot differentiate fibroadenoma from phyllodes tumour
- treatment:
 - generally conservative: serial observation
 - consider excision if size 2-3 cm and rapidly growing on serial ultrasound, if symptomatic or patient preference

Intraductal Papilloma

- solitary intraductal benign polyp
- present as nipple discharge (most common cause of spontaneous, unilateral bloody nipple discharge), breast mass, nodule on U/S
- can harbour areas of atypia or DCIS
- treatment: excision of involved duct to ensure no atypia

Ductal Hyperplasia Without Atypia

- increased number of cells within the ductal space
- cells retain benign cytology
- no treatment required
- slightly increased cancer risk if moderate or florid hyperplasia

PROLIFERATIVE LESIONS – With Atypia

Atypical Hyperplasias

- can involve ducts (ductal hyperplasia with atypia) or lobules (lobular hyperplasia with atypia)
- cells lose apical-basal orientation
- increased risk of breast cancer
- diagnosis: core or excisional biopsy
- treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

OTHER LESIONS

Fat Necrosis

- uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
- firm, ill-defined mass with skin or nipple retraction, ± tenderness
- regress spontaneously, but complete imaging ± biopsy to rule out carcinoma

Mammary Duct Ectasia

- obstruction of a subareolar duct leading to duct dilation, inflammation, and fibrosis
- may present with nipple discharge, bluish mass under nipple, local pain
- risk of secondary infection (abscess, mastitis)
- resolves spontaneously

Montgomery Tubercle

- Montgomery tubercles aka Morgagni tubercles are papular projections at the edge of the areola
- obstruction of these glands can lead to inflammation or cystic collections (cyst of Montgomery aka retroareolar cyst)
- if signs of secondary infection, start treatment for mastitis
- resolves spontaneously in weeks to years

Abscess

- lactational (see Obstetrics, OB50) vs. periductal/subareolar
- unilateral localized pain, tenderness, erythema, subareolar mass, nipple discharge, nipple inversion
- rule out inflammatory carcinoma, as indicated
- treatment: initially broad-spectrum antibiotics and I&D, if persistent total duct excision (definitive)
- if mass does not resolve: fine needle aspiration (FNA) to exclude cancer, U/S to assess for presence of abscess

Breast Cancer

Gender followed by age are the two greatest risk factors for breast cancer.

Epidemiology

- 2nd leading cause of cancer mortality in women (1st is lung cancer)
- 1/9 women in Canada will be diagnosed with breast cancer in their lifetime
- 1/27 women in Canada will die from breast cancer

Risk Factors

- gender (99% female)
- age (80% >40 years old)
- most important risk factors are prior history of breast cancer and/or prior breast biopsy (regardless of pathology)
- 1st degree relative with breast cancer (greater risk if relative was premenopausal)
- increased risk with high breast density, nulliparity, first pregnancy >30 years old, menarche <12 years old, menopause >55 years old
- decreased risk with lactation, early menopause, early childbirth
- radiation exposure (e.g. Mantle radiation for Hodgkin's disease)
- >5 years HRT

Investigations

- mammography
 - indications:
 - ♦ screening (see Table 15):
 - every 1-2 years for women age 50-69
 - positive family history in 1st degree relative: every 1-2 years starting 10 years before the youngest age of presentation
 - ♦ diagnostic: investigation of patient complaints (discharge, pain, lump)
 - ♦ follow-up after breast cancer surgery
 - findings indicative of malignancy:
 - ♦ mass that is poorly defined, spiculated border
 - ♦ microcalcifications
 - ♦ architectural distortion
 - ♦ interval mammographic changes
 - ♦ normal mammogram does not rule out suspicion of cancer based on clinical findings
- other radiographic studies:
 - ultrasound – differentiate between cystic and solid
 - MRI – high sensitivity, low specificity
 - galactogram/ductogram (for nipple discharge) – identifies lesions in ducts
 - metastatic workup as indicated (usually after surgery or if clinical suspicion of metastatic disease) – bone scan, abdo U/S, CXR, head CT

Any palpable dominant breast mass requires further investigation.

Diagnostic mammography is indicated in all patients, even in women <50 years old.

Table 15. Screening for Breast Cancer in Women of Average Risk

Test/Maneuver	Effectiveness	Level of Evidence	Recommendation
Mammography, with or without clinical examination*, women aged 40-49 years	Controversial, routine mammography with or without clinical examination, has not consistently been shown to reduce breast cancer mortality or overall mortality (7 RCTs, 7 meta-analyses)	RCTs (I)	Current evidence does not support the recommendation that screening mammography be included or excluded from the periodic health examination of women aged 40-49 with average risk of breast cancer (Grade C)
Mammography, with or without clinical examination*, women aged 50-69	Statistically significant reduction in breast cancer mortality (RR 0.76) though overall mortality not affected (7 RCTs, 5 meta-analyses)	RCTs (I)	Based on breast cancer-specific mortality, the Canadian Task Force on Preventative Health Care concluded there was good evidence for screening women aged 50-69 by mammography (and clinical breast exam).(Grade A) The best available evidence does not provide conclusive direction regarding annual versus biennial screening
Teaching of Breast Self-Examination (BSE) to women aged 40-69	Evidence of no benefit in terms of survival from breast cancer Evidence of increased number of physician visits and increased rate of benign biopsy results	RCTs (I) Non-RCTs (II-1) Cohort Studies (II-3) Case-control studies (II-3) RCTs (I) Non-RCTs (II-1)	Fair evidence of no benefit and good evidence of harm, therefore fair evidence not to recommend routine teaching of BSE from the periodic health examination (Grade D)

* The utility of adding clinical breast examination (CBE) to mammography is unclear. Some of the 7 RCTs carried out CBE and mammography in combination and some separately. As relative contributions of mammography and clinical breast exam are unknown, both maneuvers are recommended by the Canadian Task Force on Preventative Health Care.

Diagnostic Procedures

- needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
- U/S or mammography guided core needle biopsy (most common)
- fine needle aspiration (FNA): for palpable solid masses; need experienced practitioner for adequate sampling
- excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

Genetic Screening

- consider testing for BRCA1/2 if:
 - patient diagnosed with breast AND ovarian cancer
 - strong family history of breast/ovarian cancer (e.g. Ashkenazi Jewish)
 - family history of male breast cancer
 - young patient (<35 years old)

Staging (see Table 16)

- clinical:
 - tumour size by palpation, mammogram
 - nodal involvement by palpation
 - metastasis by physical exam, CXR and abdo U/S (or CT chest/abdo/pelvis), bone scan (usually done post-op if node-positive disease)
- pathological:
 - tumour size
 - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear and mitotic grade
 - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, sentinel node positive/negative
 - estrogen receptor (ER) + progesterone receptor (PR) testing
 - Her2Neu receptor testing
 - margins: negative, <1 mm, positive
 - lymphovascular invasion (LVI)
 - extensive in situ component (EIC): DCIS in surrounding tissue
 - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIB

A Comparison of Aspiration Cytology and Core Needle Biopsy According to Tumour Size of Suspicious Breast Lesions

Diagn Cytopathol 2008; 36(1):26-31

Background: The purpose of the study was to compare the accuracy of FNAC, CNB, and combined biopsy according to tumour size of suspicious breast lesions.

Methods: Ultrasound guided FNAC and CNB were performed in 264 patients with suspicious breast lesions from August, 1997 to August, 2002. The lesions were divided in four groups according to the tumour size in the histopathology report: lesions smaller than 1 cm, between 1 and 2 cm, between 2 and 5 cm, and lesions greater than 5 cm. The final surgical histopathology results identified 222 (84%) malignant cases and benign lesions summed 42 (16%).

Results: For lesions smaller than 1 cm, FNAC, CNB and combined biopsy were equivalent for all parameters. For lesions between 1 and 2 cm, FNAC and CNB were equivalent. Combined biopsy showed higher absolute sensitivity ($P = 0.007$) and lower inadequate rate ($P = 0.03$) when compared to FNAC. However, when combined biopsy and CNB were compared, no difference were found. For lesions between 2 and 5 cm, CNB showed higher absolute sensitivity ($P < 0.001$) and lower inadequate rate ($P < 0.007$) when compared to FNAC. Combined biopsy showed higher sensitivity compared to FNAC and CNB alone ($P < 0.05$) in this group. For lesions greater than 5 cm, FNAC and CNB were equivalent for all parameters. Combined biopsy only showed higher absolute sensitivity ($P = 0.04$) when compared with FNAC alone.

Conclusions: The combination of FNAC and CNB can improve the diagnosis of suspicious breast lesions greater than 1 cm. However, for lesions smaller than 1 cm, any modality has technical limitations.

Table 16. Staging of Breast Cancer (American Joint Committee on Cancer)

Stage	Tumour	Nodes (regional) (clinical)	Metastasis	Survival (5-year)
0	in situ	None	None	99%
I	<2 cm	None	None	94%
II A	<2 cm	Mobile ipsilateral	None	85%
II B	2-5 cm or >5 cm	None or mobile ipsilateral None	None None	70%
III A	Any size	Fixed ipsilateral or internal mammary	None	52%
III B	Skin/chest wall invasion	Any	None	48%
III C	Any size	Ipsilateral infraclavicular/internal mammary plus axillary nodes; ipsilateral supraclavicular node(s) ± axillary nodes	None	33%
IV	Any	Any	Distant	18%

Favourable Features	Unfavourable Features
<ul style="list-style-type: none"> • <2 cm • Grade I (low grade) • Node negative • Stage I • ER positive • Mucinous pattern 	<ul style="list-style-type: none"> • >5 cm • Grade III (high grade) • Node positive • Stage IV • ER negative • Inflammatory cancer • Her2Neu positive • Positive margins • LVI • EIC • Dermal lymphatics involved

Pathology

- non-invasive (cannot penetrate basement membrane):
 - ductal carcinoma *in situ* (DCIS):
 - ♦ proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
 - ♦ 80% non-palpable, detected by screening mammogram
 - ♦ risk of invasive ductal carcinoma in same breast up to 35% in 10 years
 - ♦ treatment:
 - lumpectomy with wide excision margins + radiation (5-10% risk invasive cancer)
 - mastectomy if large area of disease, high grade or multifocal (risk of invasive cancer reduced to 1%)
 - possibly tamoxifen as an adjuvant treatment
 - 99% 5-year survival
 - lobular carcinoma *in situ* (LCIS):
 - ♦ neoplastic cells completely contained within breast lobule
 - ♦ no palpable mass, no mammographic findings, usually incidental finding on breast biopsy for another indication
 - ♦ treatment
 - clinical follow-up
 - chemoprevention (tamoxifen)
 - surgery (uncommon)
 - ♦ not a precursor lesion, but considered a risk factor for breast cancer development
- invasive:
 - invasive ductal carcinoma (most common 80%):
 - ♦ originates from ductal epithelium and infiltrates supporting stroma
 - ♦ characteristics: hard, scirrhous, infiltrating tentacles, gritty on cross-section
 - invasive lobular carcinoma (8-15%):
 - ♦ originates from lobular epithelium
 - ♦ 20% bilateral (i.e. more often than infiltrating ductal carcinoma)
 - ♦ does not form microcalcifications, harder to detect mammographically (may benefit from MRI)
 - Paget's disease (1-3%):
 - ♦ ductal carcinoma that invades nipple with scaling, eczematoid lesion
 - inflammatory carcinoma (1-4%):
 - ♦ ductal carcinoma that invades dermal lymphatics
 - ♦ most aggressive form of breast cancer
 - ♦ clinical features: erythema, skin edema, warm, swollen and tender breast ± lump
 - ♦ peau d'orange indicates advanced disease (IIb-IV)
 - male breast cancer (<1%):
 - ♦ most commonly invasive ductal carcinoma
 - ♦ often diagnosed at later stages
 - ♦ stage-for-stage similar prognosis to breast cancer in females
 - ♦ consider genetic testing
 - sarcomas: rare
 - ♦ most commonly phyllodes tumour, a variant of fibroadenoma with potential for malignancy
 - lymphoma: rare
 - other: papillary, medullary, mucinous, tubular cancers
 - ♦ generally better prognosis

Treatment

Table 17. Breast Cancer Treatment by Stage

Stage	Primary Treatment Options	Adjuvant Systemic Therapy
0 (<i>in situ</i>)	BCS + radiotherapy BCS alone if margins >1 cm and low nuclear grade Mastectomy* ± SLNB	None
I	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	May not be needed; discuss risks/benefits of chemotherapy and tamoxifen
II	BCS + axillary node dissection + radiotherapy Mastectomy* + axillary node dissection/SLNB	Chemotherapy for premenopausal women or postmenopausal and estrogen receptor (ER) negative, follow by tamoxifen if ER positive
III	Likely mastectomy + axillary node dissection + radiotherapy	Neoadjuvant therapy may be considered i.e. preoperative chemotherapy and/or hormone therapy. Adjuvant radiation and chemotherapy may also be appropriate (i.e. post-op)
Inflammatory	Likely mastectomy + axillary node dissection + radiotherapy	Neoadjuvant therapy
IV	Surgery as appropriate for local control	Primary treatment is systemic therapy i.e. chemotherapy and/or hormone therapy

BCS = breast-conserving surgery; SLNB = sentinel lymph node biopsy

*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient's preference since choice of local treatment does not significantly affect survival if local control is achieved

Primary Surgical Treatment

- breast-conserving surgery (BCS) – lumpectomy with wide local excision
 - for treatment of stage I and II disease
 - must be combined with radiation for survival equivalent to mastectomy
 - contraindications:
 - ♦ high risk of local recurrence – extensive malignant-type calcifications on mammogram, multifocal primary tumours, or failure to obtain tumour-free margins after re-excision
 - ♦ contraindications to radiation therapy (pregnancy, previous radiation, collagen vascular disease)
 - ♦ large tumour size relative to breast
- mastectomy
 - radical mastectomy (rarely done anymore) – removes all breast tissue, skin, pectoralis muscle, axillary nodes
 - modified radical mastectomy (MRM) – removes all breast tissue, skin, and axillary nodes
 - simple mastectomy – removes all breast tissue and skin
 - see Plastic Surgery, PL31 for breast reconstruction
- axillary lymph node dissection (ALND)
 - performed if SLNB is positive or nodes are clinically concerning
 - risk of arm lymphedema (10-15%), decreased arm sensation, shoulder pain
- sentinel lymph node biopsy (SLNB)
 - technetium-99 ± blue dye injected at tumour site prior to surgery to identify sentinel node(s)
 - intraoperative frozen section
 - proceed with ALND if positive
 - 5% false negative rate

Adjuvant/Neoadjuvant

- radiation
 - indications:
 - ♦ decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy (is >4 nodes positive or tumour >5 cm)
 - ♦ inoperable locally advanced cancer
 - axillary nodal radiation may be added if nodal involvement
- hormonal
 - indications:
 - ♦ ER positive plus node-positive or high-risk node-negative
 - ♦ palliation for metastases
 - tamoxifen if premenopausal or aromatase inhibitors (e.g. anastrozole)
 - ovarian ablation (e.g. goserelin/GnRH agonist, oophorectomy), progestins (e.g. megestrol acetate), androgens (e.g. fluoxymesterone) are other options
- chemotherapy
 - indications:
 - ♦ ER negative plus node-positive or high-risk node-negative
 - ♦ ER positive and young age
 - ♦ stage I disease at high risk of recurrence (high grade, lymphovascular invasion)
 - ♦ palliation for metastatic disease

Post-Treatment Follow-up

- visits q3-6 months x 2 years and annually thereafter (frequency is controversial)
- annual mammography; no other imaging unless clinically indicated
- psychosocial support and counselling

Local/Regional Recurrence

- recurrence in treated breast or ipsilateral axilla
- 1% per year up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

Metastasis

- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation

Breast conserving surgery can be offered to most women with stage I/II disease.

Twenty-year Follow-up of a Randomized Study comparing Breast-conserving Surgery with Radical Mastectomy for Early Breast Cancer

Veronesi U, et al. *NEJM* 2002; 16:1227-32

Background: Women enrolled in a randomized trial to compare the efficacy of radical mastectomy (RM) with that of breast-conserving surgery (BCS) were followed over a 20-year period for long-term outcomes including disease recurrence and survival.

Methods: From 1973-1980, 701 women with breast cancers measuring <2 cm in diameter were randomly assigned to undergo RM (349 patients) or BCS followed by radiotherapy to the ipsilateral breast (352 patients).

Results: Rates of ipsilateral disease recurrence were lower in patients treated with RM compared to BCS (crude cumulative incidence 2.3% versus 8.8% after 20 years, $P < 0.001$). However, there was no significant difference in rates of contralateral breast malignancies, metastatic spread, or second primary malignancies between the two groups. All-cause mortality rates were 41.7% in the BCS group and 41.2% in the RM group ($P = 1.0$), with mortality rates due to breast cancer of 26.1% and 24.3% respectively ($P = 0.8$).

Conclusions: The long-term survival rate among patients treated with breast-conserving surgery and adjuvant radiotherapy is the same as that among patients treated with radical mastectomy.

There is no survival benefit of mastectomy over lumpectomy plus radiation for stage I and II disease.

Surgical Endocrinology

Thyroid and Parathyroid

- see [Endocrinology](#), E28 and [Otolaryngology](#), OT32, OT34

Adrenal Gland

- see [Endocrinology](#), E35
- functional anatomy:
 - cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), reticularis (sex steroids)
 - medulla: catecholamines (epinephrine, norepinephrine)
- types: functional (e.g. Cushing's syndrome, Conn's syndrome) or non-functional

INCIDENTALOMA

- adrenal mass discovered by investigation of unrelated symptoms

Epidemiology

- benign adenoma (38%) > metastases to adrenal (22%) >> cyst, carcinoma, pheochromocytoma, neuroblastoma
- metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, kidney
- peak incidence of carcinoma: females ages 50-60, risk decreases with increasing age and male gender

Investigations

- MRI, CT: size >6 cm is best predictor of primary adrenal carcinoma (92% are >6 cm)
- functional studies:
 - pheochromocytoma: 24 hour urine epinephrine, norepinephrine, metanephrine, normetanephrine, VMA (vanillylmandelic acid)
 - Cushing's: 24 hour urine cortisol or 1 mg overnight dexamethasone suppression test
 - aldosteronoma: electrolytes, aldosterone: renin level, saline suppression test if appropriate
 - adrenal androgens: 17-OH progesterone, DHEAS
- FNA biopsy: if suspect metastasis to adrenal (must exclude pheochromocytoma first)
 - indicated if history of cancer or patient is smoker
- iodocholesterol scintigraphy: may distinguish benign vs. malignant disease

Treatment

- functional tumour: resect
- non-functioning tumour:
 - >6 cm: resect
 - 3-6 cm: MRI (T2 density, shape, margins), more likely to resect in females and if <60 years old
 - <3 cm: follow with repeat CT in 12-18 months

Skin Lesions

- see [Dermatology](#), D6; [Emergency](#), ER17; [Plastic Surgery](#) PL14

Common Medications

Antiemetics

- dimenhydrinate (Gravol®) 25-50 mg PO/IV/IM q4-6h prn
- prochlorperazine (Stemetil®) 5-10 mg PO/IV/IM bid-tid prn
- metochlopramide (Maxeran®) 10 mg IV/IM q2-3h prn, 10-15 mg PO qid (30 min before meals and qhs)
- ondansetron (Zofran®)
- granisetron (Kytril®) 1 mg PO bid (for nausea from chemotherapy/radiation)

Analgesics

- acetaminophen ± codeine (Tylenol® #3/plain) 1-2 tabs q4-6h PO/PR prn
- morphine 2.5-10 mg IM/SC q 4-6h prn + 1-2 mg IV q1h prn for breakthrough
- ketorolac (Toradol®)
- Percocet® (acetaminophen/oxycodone, 325/5 mg) 1-2 tabs PO q4-6h prn

DVT Prophylaxis

- heparin 5000 units SC bid, if cancer patient then heparin 5000 units SC tid
- dalteparin (Fragmin®) 5000 units SC daily
- enoxaparin (Lovenox®) 40 mg SC daily

Antidiarrheals

- loperamide (Imodium®) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d
- diphenoxylate + atropine (Lomotil®) 2 tabs/10 ml PO qid

Laxatives

- sennosides (Senokot®) 1-2 tabs qhs
- docusate sodium (Colace®) 100 mg PO bid
- glycerine supp 1 tab PR prn
- lactulose 15-30 ml PO qid prn
- milk of magnesia (MOM) 30-60 ml PO qid prn
- bisacodyl (Dulcolax®) 10-15 mg PO prn

Sedatives

- zopiclone (Imovane®) 5-7.5 mg PO qhs prn
- lorazepam (Ativan®) 0.5-2 mg PO/SL qhs prn

Antibiotics

- cefazolin (Ancef®) 1 g IV/IM on call to OR or q8h – GP except *Enterococcus*, GN only *E. coli*, *Klebsiella* and *Proteus*
- cefalexin (Keflex®) 250-500 mg PO qid – *Listeria*, GP except *Enterococcus*, GN only *E. coli*, *Klebsiella* and *Proteus*
- ceftriaxone 1-2 g IM/IV q24h – broad coverage including *Pseudomonas*
- ampicillin 1-2 g IV q4-6h – *Listeria*, GP (*Enterococcus*) except *Streptococcus* and *E. coli*, oral anaerobes except *Bacteroides*
- gentamicin 3-5 mg/kg/day IM/IV divided q8h; monitor creatinine, gentamicin levels – GN including *Pseudomonas*
- ciprofloxacin 400 mg IV q12h, 500 mg PO bid – GN including *Pseudomonas*
- metronidazole (Flagyl®) 500 mg PO/IV bid, (500 mg PO tid for *C. difficile*) – anaerobes
- clindamycin 600-900 mg IV q8h, 150-400 mg PO qid – GP except *Enterococcus*, anaerobes

Over-the-Counter Medications

- Pepto-Bismol® (bismuth subsalicylate) 2 tabs or 30 ml PO q30min-1hr up to 8 doses/day
 - side effects: black stools, risk of Reye's syndrome in children
- Alka-Seltzer® (ASA + citrate + bicarbonate) 2 tabs in 4 oz water PO q4h prn, max 8 tabs
- Maalox® (aluminum hydroxide + magnesium hydroxide) 10-20 ml or 1-4 tabs PO prn
- Tums® (calcium carbonate) 1-3 g PO q2h prn
- Rolaids® (calcium carbonate and magnesium hydroxide) 2-4 tabs PO q1h prn, max 12 tabs/day

Physiology and Pathology of Aging

Table 2. Changes Occurring Frequently with Aging

System	Physiological Changes	Pathological Changes
Neurologic	Decreased wakefulness, decreased brain mass, cerebral blood flow	Increased insomnia, neurodegenerative disease, stroke, decreased reflex response
Special Senses	Decreased lacrimal gland secretion, lens transparency, dark adaptation, decreased sense of smell and taste	Increased glaucoma, cataracts, macular degeneration, presbycusis, presbyopia, tinnitus, vertigo, oral dryness
Cardiovascular	Increased sBP, dBP, decreased HR, CO Decreased vessel elasticity, cardiac myocyte size and number, beta-adrenergic responsiveness	Increased atherosclerosis, CAD, MI, CHF, hypertension, arrhythmias
Respiratory	Increased tracheal cartilage calcification, mucous gland hypertrophy Decreased elastic recoil, mucociliary clearance, pulmonary function reserve	Increased COPD, pneumonia, pulmonary embolism
Gastrointestinal	Increased intestinal villous atrophy Decreased esophageal peristalsis, gastric acid secretion, liver mass, hepatic blood flow, calcium and iron absorption	Increased cancer, diverticulitis, constipation, fecal incontinence, hemorrhoids, intestinal obstruction
Renal and urologic	Increased proteinuria, urinary frequency Decreased renal mass, creatinine clearance, urine acidification, hydroxylation of vitamin D, bladder capacity	Increased urinary incontinence, nocturia, BPH, prostate cancer, pyelonephritis, nephrolithiasis, UTI
Reproductive	Decreased androgen, estrogen, sperm count, vaginal secretion Decreased ovary, uterus, vagina, breast size	Increased breast and endometrial cancer, cystocele, rectocele, atrophic vaginitis
Endocrine	Increased NE, PTH, insulin, vasopressin Decreased thyroid and adrenal corticosteroid secretion	Increased DM, hypothyroidism, stress response
Musculoskeletal	Increased calcium loss from bone Decreased muscle mass, cartilage	Increased arthritis, bursitis, osteoporosis, polymyalgia rheumatica
Integumentary	Atrophy of sebaceous and sweat glands Decreased epidermal and dermal thickness, dermal vascularity, melanocytes, collagen synthesis	Increased lentigo, cherry hemangiomas, pruritus, seborrheic keratosis, herpes zoster, decubitus ulcers, skin cancer
Psychiatry	None	Increased depression, dementia, delirium, suicidality, substance abuse, anxiety, insomnia

Differential Diagnoses of Common Presentations

Constipation

- see Gastroenterology, G25

Definition

- less than 3 bowel movements in one week and/or hard stools, straining, sense of blockade, manual maneuvers or incomplete evacuation on more than 25% of occasions

Epidemiology

- chronic constipation increases with age (up to 1/3 of patients >65 years experience constipation)

Pathophysiology

- impaired rectal sensation
- colorectal dysmotility

Risk Factors

- immobility
- dehydration
- polypharmacy
- drugs – narcotics, calcium channel blockers
- low fibre/calorie diet
- obstructive lesions – bowel obstruction, cancer, diverticular disease, IBD, strictures
- altered colonic motility – IBS, colonic inertia
- neurological – sacral cord dysfunction, Parkinson's disease, stroke
- metabolic – diabetes, hypokalemia, hypercalcemia
- psychiatric – depression, dementia

Treatment

- non-pharmacological
 - increase fibre intake
 - adequate fluid intake
 - discourage chronic laxative use
 - regular exercise
 - review medication regime, reduce dosages or substitute
- pharmacologic
 - see *Common Medications*, GM14

Delirium, Dementia and Depression

- see Psychiatry, PS17, PS18, PS8 and Neurology, N10

Delirium Prevention in Elderly

- ensure optimal vision and hearing to support orientation (e.g. clean, appropriate eyewear and hearing aids)
- provide adequate nutrition and hydration
- encourage regular mobilization to build and maintain strength, balance and endurance
- avoid unnecessary medications and monitor for drug interactions
- avoid bladder catheterization if possible

Elder Abuse

Definition

- includes physical abuse, sexual abuse, emotional or psychological abuse, financial abuse, abandonment and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada
- in the U.S., most states have criminal penalties for elder abuse, laws vary from state to state

Epidemiology

- in Canada, approximately 4% of elderly persons living in private homes have suffered abuse
- in the U.S., estimates of the frequency of elder abuse range from 3-8%
- physician reporting is mandatory only in Newfoundland, Nova Scotia and PEI; in Ontario, only abuse occurring in nursing homes is mandatory to report
- insufficient evidence to include/exclude screening in the Periodic Health Exam

**Red Flags for Elder Abuse**

1. Delay in seeking medical attention
2. Disparity in histories
3. Implausible or vague explanations
4. Frequent emergency room visits for exacerbations of chronic disease despite plan for medical care and adequate resources
5. Presentation of functionally impaired patient without designated caregiver
6. Lab findings inconsistent with history

Risk Factors

- situational factors
 - isolation, lack of money, lack of community resources for additional care, unsatisfactory arrangements
 - inadequate access to appropriate beds, low staff-to-patient ratio, low pay rates for staff, low educational level of staff, staff burnout
- characteristics of the victim
 - physical or emotional dependence on caregiver, lack of close family ties, history of family violence, age over 75 years, recent deterioration in health, dementia
- characteristics of the perpetrator
 - stress caused by financial, marital or occupational factors, deterioration in health, bereavement, substance abuse, mental illness, related to victim, living with victim, long duration of care for victim (mean 9.5 years)

Management

- assess safety and determine capacity to make decisions about living arrangements
- establish need for hospitalization or alternate accommodation (e.g. immediate risk of physical harm by self or caregiver)
- involve multidisciplinary team (e.g. nurse, social worker, family members and physicians including geriatrician, psychiatrist or family physician)
- contact local resources (e.g. legal aid, elderly advocacy centre, crisis centre)
- educate and assist caregiver, link up with community resources (e.g. personal support worker, homemaking services, caregiver support groups)

Failure to Thrive (Frailty)

**Four Syndromes in Failure to Thrive**

My Pa Can't Drive
 Malnutrition
 Physical impairment
 Cognitive impairment
 Depression

Definition

- declining independence and functional capacity with loss of vigor and/or weight in older adults
- not an inevitable consequence of aging

Etiology

- four syndromes are prevalent in older patients with failure to thrive: malnutrition, functional impairment, cognitive impairment and depression

**Functional Assessment (ADLs and IADLs)****ADLs: ABCDE-TT**

Ambulating
 Bathing
 Continence
 Dressing
 Eating
 Transferring
 Toileting

IADLs: SHAFT-TT

Shopping
 Housework
 Accounting/Managing finances
 Food preparation
 Transportation
 Telephone
 Taking medications

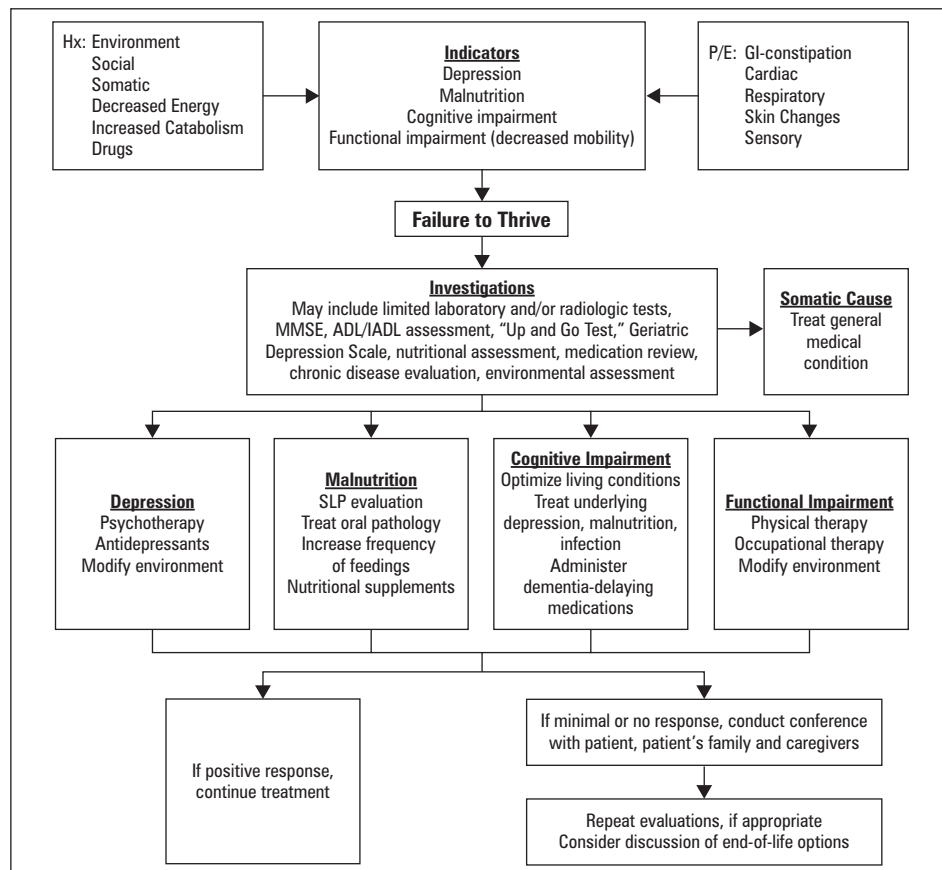

Figure 1. Evaluation of the Geriatric Patient who is Failing in the Community

Adapted from: Sarkisian CA, Lachs MS. "Failure to thrive" in older adults. *Ann Intern Med* 1996; 24:1072-1078.

Table 3. Common Medical Conditions Associated with Failure to Thrive

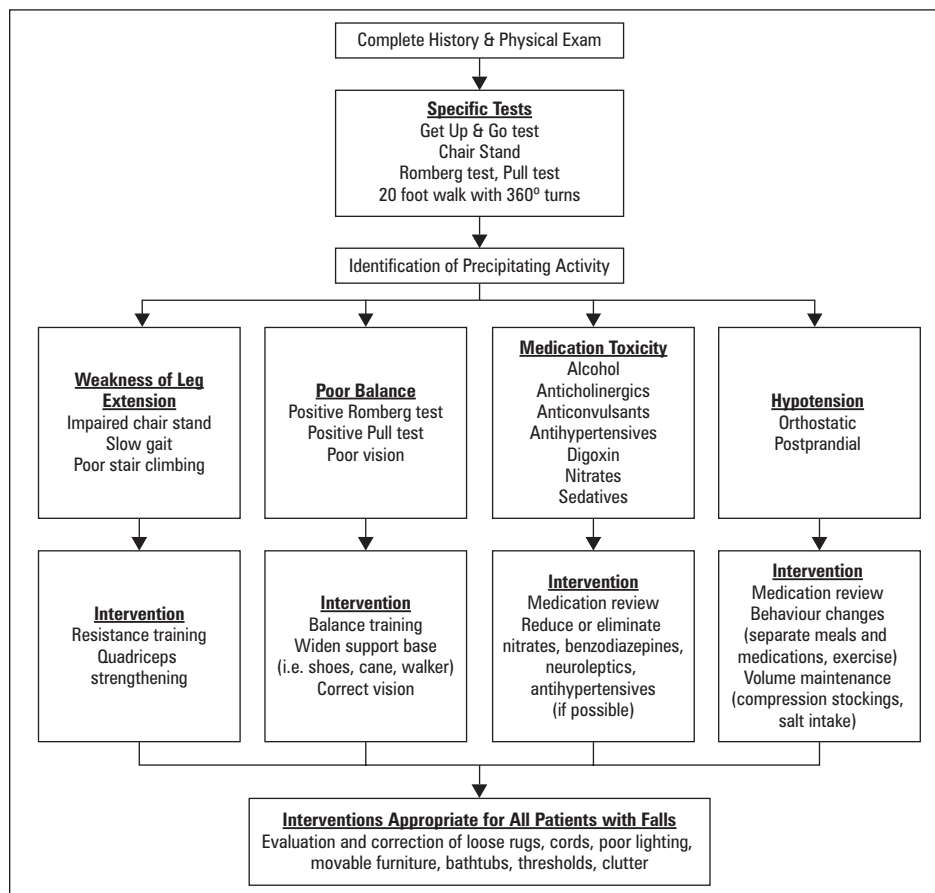

Medical Condition	Cause of Failure to Thrive
Cancer	Metastases, malnutrition, cachexia
Chronic lung disease	Respiratory failure
Chronic renal insufficiency	Renal failure
Chronic steroid use	Steroid myopathy, diabetes, osteoporosis, vision loss
Cirrhosis, hepatitis	Hepatic failure
Depression, other psychiatric disorder	Major depression, psychosis, poor functional status, cognitive loss
Diabetes	Malabsorption, poor glucose homeostasis, end-organ damage
Gastrointestinal surgery	Malabsorption, malnutrition
Hip, long bone fracture	Functional impairment
Inflammatory bowel disease	Malabsorption, malnutrition
Myocardial infarction, congestive heart failure	Cardiac failure
Recurrent UTI, pneumonia	Chronic infection, functional impairment
Rheumatologic disease (GCA, RA, SLE)	Chronic inflammation
Stroke	Dysphagia, depression, cognitive loss, functional impairment
Tuberculosis, other systemic infection	Chronic infection

Verdery RB. "Clinical evaluation of failure to thrive in older people." *Clin Geriatr Med* 1997; 13:769-78.

Falls

Epidemiology

- 30-40% of people >65 years old and ~50% of people >80 years old fall each year
 - approximately 20% of falls require medical attention
 - 5% of falls lead to hospitalization
 - 5-10% with serious injuries (e.g. hip fracture, head injury, laceration)
 - 1-2% of falls associated with hip fracture
 - 15% die in hospital, 33% 1-year mortality
 - between 25-75% do not recover to previous level of ADL function
 - mortality increases with age (171/100,000 in men >85 years old) and type of injury (25% with hip fracture die within 6 months)

**Figure 2. Approach to Falls in the Elderly**

Adapted from: Ganz, DA, Bao Y, Shekelle PE, Rubenstein LZ. Will my patient fall? *JAMA* 2007; 297: 77-86.

Tinetti ME, Baker DI, McAvay G, et al. A multifactorial intervention to reduce the risk of falling among elderly people living in the community.

NEJM 1994; 331(13):821-827.

Key Physical Findings in the Elderly Patient Who Falls or Nearly Falls

I HATE FALLING

Inflammation of joints
Hypotension (orthostatic changes)
Auditory and visual abnormalities
Tremor
Equilibrium (balance) problem
Foot Problems
Arrhythmia, heart block or valvular disease
Leg-length discrepancy
Lack of conditioning (generalized weakness)
Illness
Nutrition
Gait disturbance

Fuller, G. Falls in the elderly.

Am Fam Phys 2001; 61(7): 2159-2172.

Drugs That May Increase the Risk of Falling

Sedative-hypnotic and anxiolytic drugs (especially long-acting benzodiazepines)
Tricyclic antidepressants
Major tranquilizers (phenothiazines and butyrophenones)
Antihypertensive drugs
Cardiac medications
Corticosteroids
Nonsteroidal anti-inflammatory drugs
Anticholinergic drugs
Hypoglycemic agents
Alcohol

Fuller, G. Falls in the elderly.

Am Fam Phys 2001; 61(7): 2159-2172.

Will My Patient Fall?

JAMA 2007; 297:77-86

Purpose: To identify the prognostic value of risk factors for future falls among older patients.

Study Selection: Prospective cohort studies of risk factors for falls that performed a multivariate analysis of such factors.

Results: Clinically identifiable risk factors were identified across 6 domains: orthostatic hypotension, visual impairment, impairment of gait or balance, medication use, limitations in basic or instrumental activities of daily living and cognitive impairment. Eighteen studies met inclusion criteria and provided a multivariate analysis including at least 1 of the risk factor domains. The estimated pretest probability of falling at least once in any given year for individuals 65 years and older was 27% (95% confidence interval, 19%-36%). Patients who have fallen in the past year are more likely to fall again [likelihood ratio range, 2.3-2.8]. The most consistent predictors of future falls are clinically detected abnormalities of gait or balance (likelihood ratio range, 1.7-2.4). Visual impairment, medication variables, decreased activities of daily living and impaired cognition did not consistently predict falls across studies. Orthostatic hypotension did not predict falls after controlling for other factors.

Conclusions: Screening for risk of falling during the clinical examination begins with determining if the patient has fallen in the past year. For patients who have not previously fallen, screening consists of an assessment of gait and balance. Patients who have fallen or who have a gait or balance problem are at higher risk of future falls.

**Fall Prevention Tips**

1. Improve lighting, especially on stairs
 2. Caution while adjusting to new bifocal prescription (poor depth perception)
 3. Siderails in bathtubs
 4. Railings on steps
 5. Connect patient to lifeline button signaling systems
 6. Remove loose mats or carpets, telephone cords and other tripping hazards
 7. Recommend support hose for varicose veins and swelling of ankles
- Goldlist B, Turpic I, Borins M. (1997). *Essential Geriatrics: Managing 6 conditions: Patient Care Canada*. 8(9).

Medication as a Risk Factor for Falls: Critical Systematic Review

J Gerontol A Biol Sci Med Sci 2007; 62(10):1172-81

Purpose: To review all original articles systematically examining medication use as a risk factor for falls or fall-related fractures in people aged more than 60 years.

Study Selection: Studies investigating "falls" or "accidental falls" and "pharmaceutical preparations" or specific groups of drugs were included. Studies not meeting the age criterion, not controlled with nonusers of target medicines or nonfallers, or with no clear definition of target medication were excluded.

Results: Twenty-eight observational studies and one randomized controlled trial met the inclusion criteria. The outcome measure was a fall in 22 studies and a fracture in 7 studies. The main group of drugs associated with an increased risk of falling was psychotropics: benzodiazepines, antidepressants, and antipsychotics. Antiepileptics and drugs that lower blood pressure were weakly associated with falls.

Conclusions: Central nervous system drugs, especially psychotropics, seem to be associated with an increased risk of falls. The quality of observational studies needs to be improved, as many appear to lack even a clear definition of a fall, target medicines, or prospective follow-up. Many drugs commonly used by older persons are not systematically studied as risk factors for falls.

Interventions for Preventing Falls in Older People Living in the Community

Cochrane Database Syst Rev 2009; 2:CD007146

Study: Cochrane systematic review. 11 RCT and quasi-RCT trials.

Population: 55,303 Patients over 60 or clearly elderly, senior, or older and living in the community.

Intervention: Any intervention to prevent falls.

Primary Outcomes: Rate of falls and number of fallers.

Results: Exercise is effective in reducing risk and rate of falls. Multifactorial assessment with a multi-professional team reduces rates of falls but not risk of falls. Limited evidence shows that environmental assessments and interventions may not reduce risk or rate of falls. Vitamin D does not appear to be effective in reducing rate of falls in all patients. Cardiac pacing in patients with carotid sinus hypersensitivity and history of syncope or falls reduces rate of falls. Home-based physiotherapy does not benefit patients with Parkinson's or stroke related mobility problems.

Conclusions: Exercise interventions reduce risk of falls in the elderly. Additional research is required to confirm and elaborate the contexts in which other interventions are effective.

Etiology

- commonly multifactorial
- extrinsic
 - environmental (e.g. home layout, lighting, stairs, footwear), accidental, abuse
 - medications/substances (e.g. alcohol)
 - month after hospital discharge, acute illness, exacerbation of chronic illness
- intrinsic
 - orthostasis/syncope
 - age-related changes and diseases associated with aging: musculoskeletal (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), metabolic (glucose, electrolytes)

Investigations

- directed by history and physical
- CBC, electrolytes, BUN, creatinine, glucose, Ca, TSH, B12, urinalysis, cardiac enzymes, ECG, CT head

Prevention

- multidisciplinary, multifactorial, health and environment risk factor screening and intervention programs in the community
- program of muscle strengthening, balance retraining and group exercise programs (e.g. tai chi)
- home hazard assessment and modification (e.g. remove rugs, add shower bars, etc.)
- withdrawal of psychotropic medication
- cardiac pacing for those with cardio-inhibitory carotid sinus hypersensitivity
- optimize eyesight and footwear

Fecal Incontinence

Epidemiology

- second leading cause of nursing home placement

Etiology

- commonly multifactorial
- pelvic floor intact
 - neurologic conditions – age-related, neuropathy, multiple sclerosis, stroke, dementia
 - tumour/trauma (e.g. brain, spinal cord, cauda equina)
 - overflow (e.g. encopresis, impaction)
 - diarrheal conditions
- pelvic floor affected
 - trauma/surgery
 - nerve/sphincter damage
 - malformation, anorectal

Risk Factors

- prior vaginal delivery
- anorectal surgery
- pelvic radiation
- diabetes
- neurologic disease
- diarrheal conditions

Investigations (if cause not apparent from history and physical)

- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

Management

- diet/bulking agent if stool is liquid or loose
- disimpaction
- anti-diarrheal agents
- regular defecation program in patients with dementia
- counsel about biofeedback therapy (retraining of pelvic floor muscles)

Gait Disorders

- see Neurology, N36

Hazards of Hospitalization

Table 4. Recommendations for Sequelae of Hospitalization in Older Patients

Sequelae	Recommendations
Malnutrition	No dietary restrictions (except diabetes), assistance, dentures if necessary, eating out of bed
Urinary incontinence	Medication review, remove environmental barriers, discontinue use of catheter
Depression	Routine screening
Adverse drug event	Medication review
Confusion/delirium	Orientation, visual and hearing aids, volume repletion, noise reduction, early mobilization, medication review, remove restraints
Pressure ulcers	Low-resistance mattress, daily inspection, repositioning every 2 hours
Infection	Early mobilization, remove unnecessary IV lines, catheters, NG tubes
Falls	Appropriate footwear, assistive devices, early mobilization, remove restraints, medication review
Hypotension/dehydration	Early recognition and repletion
Diminished aerobic capacity/loss of muscle strength/contractures	Early mobilization
Decreased respiratory function	Incentive spirometry, physiotherapy

Hypertension

- see *Family Medicine*, FM35
- 60-80% of elderly (>65 years old) have hypertension
 - 60% of these have isolated systolic HTN
- non-pharmacologic treatments are first-line, then thiazide monotherapy is recommended
- add ACEI/ARB if also atherosclerosis, DM, CHF or chronic kidney disease
- add beta-blockers if also angina or CHF
- target BP: sBP <140, 65<dBP<90; for patients with DM: sBP <130, dBP <80

Immobility

Complications

- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- musculoskeletal: atrophy, contractures, bone loss
- skin: pressure sores
- psychological: sensory deprivation, delirium, depression

Immunizations

- the following immunizations are recommended for people 65 years of age and older
 - pneumococcus – 1 dose
 - influenza – every autumn
 - appropriate boosters (e.g. tetanus every 10 years)

Malnutrition

Definition

- involuntary weight loss of $\geq 5\%$ baseline body weight or ≥ 5 kg
- hypoalbuminemia, hypocholesterolemia

Etiology

- starvation
 - decreased intake: financial, psychiatric, cognitive deficits, functional deficits, anorexia associated with chronic disease
 - decreased assimilation: impaired transit, maldigestion, malabsorption
- stress
 - acute or chronic illness/infection, chronic inflammation, abdominal pain
- mechanical
 - dental problems, dysphagia

Treatment of Hypertension in Patients 80 Years of Age or Older

NEJM 2008; 358(18):1887-98

Study: Randomized, double-blind, placebo-controlled, multicentre trial.

Patients: 3845 patients who were 80 years of age or older and had a sustained systolic blood pressure of 160 mmHg were followed for a median 1.8 years.

Intervention: Indapamide (sustained release, 1.5 mg) or matching placebo. The angiotensin-converting enzyme inhibitor perindopril (2 or 4 mg), or matching placebo, was added if necessary to achieve the target blood pressure of 150/80 mmHg.

Primary Outcome: Fatal or nonfatal stroke.

Results: The mean age of the patients was 83.6 years and mean blood pressure while sitting was 173.0/90.8 mmHg. At 2 years, the mean blood pressure while sitting was 15.0/6.1 mmHg lower in the active treatment group than in the placebo group. Active treatment was associated with a 30% reduction in the rate of fatal or nonfatal stroke (95% confidence interval CI, -1 to 51; $p=0.06$), 39% reduction in the rate of death from stroke (95% CI, 1 to 62; $p=0.05$), 21% reduction in the rate of death from any cause (95% CI, 4 to 35; $p=0.02$), 23% reduction in the rate of death from cardiovascular causes (95% CI, -1 to 40; $p=0.06$), and 64% reduction in the rate of heart failure (95% CI, 42 to 78; $p<0.001$). Fewer serious adverse events were reported in the active-treatment group (358 vs. 448 in the placebo group; $p=0.001$).

Conclusions: Antihypertensive treatment with indapamide (sustained release), with or without perindopril, in persons 80 years of age or older reduces death from stroke, death from any cause and the incidence of heart failure.

Vaccines for Preventing Influenza in the Elderly

Cochrane Database Syst Rev 2006; 3:CD004876

Purpose: To review the evidence of efficacy, effectiveness and safety of influenza vaccines in individuals aged 65 years or older.

Study Selection: Randomized, quasi-randomized, cohort and case-control studies assessing efficacy against influenza (laboratory-confirmed cases) or effectiveness against influenza-like illness (ILI) or safety.

Results: Sixty-four studies were included in the efficacy/effectiveness assessment. Results were expressed as absolute vaccine efficacy (VE). In homes for elderly individuals (with good vaccine match and high viral circulation) the effectiveness of vaccines against ILI was 23% (6% to 36%) and non-significant against influenza (RR 1.04, 95% CI 0.43 to 2.51). In elderly individuals living in the community, vaccines were not significantly effective against influenza (RR 0.19, 95% CI 0.02 to 2.01), ILI (RR 1.05, 95% CI 0.58 to 1.89), or pneumonia (RR 0.88, 95% CI 0.64 to 1.20). Vaccine administration usually induced systemic side effects (general malaise, fever, nausea, headache) more frequently than placebo, but no outcome showed statistically significant results.

Conclusions: In long-term care facilities, where vaccination is most effective against preventing complications, the aims of the vaccination campaign are fulfilled, at least in part. The usefulness of vaccines in the community is modest.

Etiology of Malnutrition in the Elderly

MEALS ON WHEELS

Medications
Emotional problems
Anorexia
Late-life paranoia
Swallowing disorders
Oral problems
Nosocomial infections
Wandering/dementia related activity
Hyperthyroid/Hypercalcemia/
Hypoadrenalism
Enteric disorders
Eating problems
Low-salt/Low-fat diet
Stones

Calculating Basic Caloric and Fluid Requirements

WHO daily energy estimates for adults > 60 years:

Female: $10.5 \times (\text{weight in kg}) + 596$

Male: $13.5 \times (\text{weight in kg}) + 487$

Maintenance fluid requirements for the elderly without cardiac or renal disease: 1500-2500 cc/24hrs.

- age-related changes
 - appetite dysregulation, decreased thirst
- mixed
 - increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

Risk Factors

- mechanical: dental problems, medical illnesses interfering with ingestion or decreasing appetite
- nutritional: medical illnesses increasing nutritional requirements or requiring dietary restrictions
- functional: difficulty shopping, preparing meals or feeding oneself due to functional impairment
- social: economic barriers to securing food, lack of availability of high quality food
- psychological: depression, poor appetite

Clinical Features

- history
 - recent weight loss, decreased food intake, constitutional symptoms, GI symptoms, recent or chronic illness, social factors
- physical examination
 - BMI <23.5 in males, <22 in females should raise concern
 - temporal wasting, muscle wasting, presence of triceps skin fold

Investigations

- CBC, electrolytes, Ca, Mg, PO₄, Cr, LFTs (albumin, INR, bilirubin), B₁₂, folate, TSH, transferrin, lipid profile, urinalysis

Osteoporosis

- see [Endocrinology](#), E43

Presbycusis

- see [Otolaryngology](#), OT20

Pressure Ulcers

- see also [Plastic Surgery](#), PL14

Risk Factors

- extrinsic factors: friction, pressure, shear force
- intrinsic factors: immobility, malnutrition, moisture, sensory loss

Table 5. Classification of Pressure Ulcers

Stage I	Changes include skin temperature, tissue consistency or sensation. An area of persistent erythema in lightly pigmented, intact skin. In darker skin, it may appear red, blue or purple.
Stage II	Partial thickness skin loss involving the epidermis, dermis or both. The ulcer is superficial and presents as an abrasion, blister or shallow crater.
Stage III	Full thickness skin loss involving damage or necrosis of subcutaneous tissue which may extend down to, but not through, underlying fascia. Presents as a deep crater with or without undermining of adjacent tissue.
Stage IV	Full thickness skin loss with extensive destruction, tissue necrosis or damage to muscle, bone or supporting structures. May have associated undermining and/or sinus tracts.

Prevention

- pressure reduction
 - frequent repositioning
 - pressure-reducing devices (static, dynamic)
- maintaining nutrition, encouraging mobility and managing incontinence

Treatment

- minimize pressure on wound
- analgesia
- wound debridement (mechanical, enzymatic, autolytic) and dressing application
- maintain moist wound environment to enable re-epithelialization
- treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)

A Systematic Review of the Use of Hydrocolloids in the Treatment of Pressure Ulcers

J Clin Nurs 2008; 17(9):1164-73

Purpose: To describe the current evidence in the field of pressure ulcer treatment with hydrocolloids and to give recommendations for clinical practice and further research.

Study Selection: Randomized controlled trials on the treatment of pressure ulcers with hydrocolloids.

Results: Twenty-nine publications, dealing with 28 different studies, met the inclusion criteria and were included in the review. Hydrocolloids were most frequently used on pressure ulcers grades 2-3. Concerning the healing of the pressure ulcer, hydrocolloids are more effective than gauze dressings for the reduction of the wound dimensions. The absorption capacity, the time needed for dressing changes, the pain during dressing changes and the side-effects were significantly in favour of hydrocolloids compared to gauze dressings. Based on the available cost-effectiveness data, hydrocolloids are less expensive compared with collagen-, saline-, and povidone-soaked gauze but more expensive than hydrogel, polyurethane foam and collagenase.

Conclusions: Based on the studies included in this review, hydrocolloids are frequently used in the treatment of grades 2 and 3 pressure ulcers and are more effective and less expensive than gauze dressings. Compared with alginates, polyurethane dressings, less-contact layers, topical enzymes, and biosynthetic dressings, hydrocolloids are less effective.

- swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
- stage IV ulcers typically warrant surgical repair
- consider other treatment options
 - negative pressure wound therapy/vacuum-assisted closure (VAC)
 - biological agents: application of fibroblast growth factor, platelet-derived growth factor to wound
 - non-contact normothermic wound therapy
 - electrotherapy

Pressure-reducing Devices

Static devices distribute pressure over a greater surface area. Dynamic devices use alternating air currents to shift pressure to different body sites.

Urinary Incontinence

- see Urology, U5

Epidemiology

- 15-30% prevalence dwelling in community and at least 50% of institutionalized seniors
- morbidity: cellulitis, pressure ulcers, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality

Pathophysiology

- in general, occurs with age: decreased bladder capacity, increased post-void residual volume, increased involuntary bladder contractions (urge incontinence)
- in elderly women: decline in bladder outlet and urethral resistance pressure promoting stress incontinence
- in elderly men: prostatic enlargement can cause overflow and urge incontinence

Transient Causes of Incontinence

DIAPERS

Delirium
Infection
Atrophic urethritis/vaginitis
Pharmaceuticals
Excessive urine output
Restricted mobility
Stool impaction

Driving Competency

Reporting Requirements

- physician reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia and Alberta, where it is discretionary
- in Ontario, drivers >80 years old are not automatically required to pass a road test in order to renew their driver's license unless there are indications to suggest road safety risks; all drivers >80 years old must have a vision and knowledge test and participate in a 90-minute group education session to renew their license every 2 years
- in the U.S., varies by states, please refer to the AMA Physician's Guide to Assessing and Counseling Older Drivers for American recommendations, www.ama-assn.org/ama/pub/category/10791.html

Conditions That May Impair Driving

- alcohol
 - patients with a history of impaired driving and those deemed to have a high probability of future impaired driving should not drive any motor vehicle until further assessed
 - alcohol dependence or abuse: if suspected, should be advised not to drive
 - alcohol withdrawal seizure: must complete a rehabilitation program and remain abstinent and seizure-free for 6 months before driving
- blood pressure abnormalities
 - hypertension: sustained BP >170/110 should be evaluated carefully
 - hypotension: if syncopal, discontinue until attacks are treated and preventable
- cardiovascular disease
 - suspected asymptomatic CAD or stable angina: no restrictions
 - STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for one month following hospital discharge
 - NSTEMI with minor LV damage, unstable angina: no driving for 48 hours if percutaneous coronary intervention (PCI) performed or 7 days if no PCI performed
- cerebrovascular conditions
 - TIA: should not be allowed to drive until a medical assessment is completed
 - stroke: should not drive for at least one month; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure

Systematic Review of Driving Risk and the Efficacy of Compensatory Strategies in Persons with Dementia

J Am Geriatr Soc 2007; 55:878-84

Purpose: To determine whether persons with dementia are at greater driving risk and, if so, to estimate the magnitude of this risk and determine whether there are efficacious methods to compensate for or accommodate it.

Study Selection: Systematic review of the case-control studies of drivers with a diagnosis of dementia.

Results: Drivers with dementia universally exhibited poorer performance on road tests and simulator evaluations. The one study that used an objective measure of motor vehicle crashes found that the crash risk in persons with dementia was 2 to 2.5 times greater than matched controls. No studies were found that examined the efficacy of methods to compensate for or accommodate the decreased driving performance.

Conclusions: Drivers with dementia are poorer drivers than cognitively normal drivers, but studies have not consistently demonstrated higher crash rates. Clinicians and policy makers must take these findings into account when addressing issues pertinent to drivers with a diagnosis of dementia.

Key Factors to Consider in Older Drivers

SAFEDRIVE

Safety record

Attention (e.g. concentration lapses, episodes of disorientation)

Family observations

Ethanol abuse

Drugs

Reaction time

Intellectual impairment

Vision/Visuospatial function

Executive functions (e.g. planning, decision-making, self-monitoring behaviours)

Adapted from: Wiseman E.J. The older driver: a handy tool to assess competence behind the wheel. *Geriatrics*. 1996;51:36-45

- chronic obstructive pulmonary disease
 - mild/moderate impairment: no restrictions
 - moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen
- cognitive impairment/dementia
 - moderate to severe dementia is a contraindication to driving; defined as the “inability to independently perform 2 or more IADLs or any basic ADL”
 - patients with mild dementia should be assessed; if indicated, refer to specialized driving testing centre; if deemed fit to drive, re-evaluate patient every 6-12 months
 - poor performance on MMSE, clock drawing or Trails B suggests a need to investigate driving ability further
 - MMSE score alone (whether normal or low) is insufficient to determine fitness to drive
- diabetes
 - diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular or cerebrovascular disease)
 - insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 months
- drugs
 - be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants
 - degree of impairment varies: patients should be warned of the medication/withdrawal effect on driving
- hearing loss
 - effect of impaired hearing on ability to drive safely is controversial
 - acute labyrinthitis, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves
- musculoskeletal disorders
 - physician's role is to report etiology, prognosis and extent of disability (pain, range of motion, coordination, muscle strength)
- post-operative
 - outpatient, conscious sedation: no driving for 24 hours
 - outpatient, general anesthesia: no driving for ≥24 hours
- seizures
 - first, single, unprovoked: no driving for 3 months until complete neurologic assessment, EEG, CT head
 - epilepsy: can drive if seizure-free on medication and physician has insight into patient compliance
- sleep disorders
 - if patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive
- visual impairment
 - visual acuity: contraindicated to drive if <20/50 with both eyes examined simultaneously
 - visual field: contraindicated to drive if <120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

Health Care Institutions

- names of community health care institutions, types of facilities and services offered vary between geographical locations
- factors to consider when seeking services/institutions include level of care required, support networks, duration of stay and cost

Table 6. Classification of Health Care Services and Institutions

Institution/Service	Description
Community Support Services	Health care services offered at home for those who can live independently at home or under the care of family members including professional health care services, personal care and support (ADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks, etc.)
Residential	Divided into short (<60-90 days/year) and long (indefinite) stay
a) Seniors Affordable Housing	Seniors who live independently and manage their own care but prefer to live near other seniors; usually has accessibility features and rent is adjusted based on income
b) Retirement/Nursing Home	Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned
c) Supportive Housing	Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment and may offer some physiotherapy and rehabilitation services
d) Long-term Care/Skilled Nursing Facility	Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital
e) Hospice	Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤ 3 months

Palliative and End of Life Care

Principles and Quality of Life

- support, educate and treat both patient and family
- address physical, psychological, social and spiritual needs
- focus on symptom management and comfort measures
- offer therapeutic environment and bereavement support
- ensure maintenance of human dignity

End of Life Care Discussions

When to Initiate End of Life Care Discussions

- recent hospitalization for serious illness
- severe progressive medical condition(s)
- death expected within 6 to 12 months
- patient inquires about end of life care

Suggested Topics for Discussion

- goals of care (disease vs. symptom management)
- advance directives, power of attorney, public guardian and trustee
- treatment options and likelihood of success
- common medical interventions
 - mechanical ventilation
 - antibiotic therapy
 - feeding tubes
- resuscitation options and likelihood of success (Full Code vs. DNR status including preferences for CPR, intubation, ICU admission, artificial hydration)

Power of Attorney

- see Ethical, Legal and Organizational Aspects of Medicine, ELOAM4

Instructional Advance Directives

- see [Ethical, Legal and Organizational Aspects of Medicine](#), ELOAM4

Symptom Management

Table 7. Management of Common End-of-Life Symptoms

Symptom	Non-Pharmacologic Management	Pharmacologic Management
Constipation	Rule out obstruction, impaction, anorectal disease; hydration and high fibre intake; increase mobility	Stop unnecessary opioids and medications with anticholinergic side effects; provide stool softener (e.g. docusate sodium), increase peristalsis (e.g. senna), alter water and electrolyte secretion (e.g. magnesium hydroxide)
Death Rattle/Increased Pulmonary Secretions	Oral suctioning Discontinue unnecessary IV solutions	Scopolamine SC or transdermal
Dry mouth	Oral hygiene q2h, ice cubes, sugarless gum	Artificial saliva substitutes, bethanechol, pilocarpine 1% solution as mouth rinse
Dysphagia	Frequent small feeds, ideally seated, keep head of bed elevated for 30 minutes after eating, suction as necessary	Treat painful mucositis (diphenhydramine: lidocaine: Maalox® in a 1:2:8 mixture), candidiasis (fluconazole)
Dyspnea	Elevate head of bed, eliminate allergens, open window/use fan	Oxygen, bronchodilators, opioids (e.g. morphine, hydromorphone)
Hiccups	Dry sugar, breathing in paper bag	Chlorpromazine, haloperidol, metoclopramide, baclofen, marijuana
Nausea and Vomiting	Frequent and small meals, avoid offensive strong odours, treat constipation if present	Raised ICP: dexamethasone Anticipatory nausea, anxiety: lorazepam Vestibular disease, vertigo: dimenhydrinate Drug induced, hepatic or renal failure: prochlorperazine, haloperidol GERD: PPI or H2 antagonist Gastric stasis: metoclopramide Bowel obstruction: metoclopramide, dexamethasone, octreotide
Pain	Hot and cold compresses, music therapy, relaxation techniques, individualized program of physical activity designed to improve flexibility, strength and endurance	Nociceptive pain: non-opioids (NSAIDs, acetaminophen), weak opioids (codeine, hydrocodone, oxycodone), strong opioids (morphine, hydromorphone, oxycodone, fentanyl) Neuropathic pain: anticonvulsants (gabapentin, pregabalin), antidepressants (TCAs, SSRIs), steroids (dexamethasone) Bony pain: non-opioids, weak opioids, bisphosphonates, radiation therapy
Pruritus	Bathing with tepid water, avoid soap, bath oils; sodium bicarbonate for jaundice	Antihistamines, phenothiazines, topical corticosteroids, calamine lotion
Weakness	Modify environment and activities to decrease energy expenditure	Treat insomnia, anemia, depression; consider psychostimulants

AGS Panel on Persistent Pain in Older Persons. The management of persistent pain in older persons. *J Am Geriatr Soc* 2002; 50(6): Supplement.
Knowles, S. Symptoms management in palliative care. *On Continuing Practice* 1993; 20(1): 20-25.

Geriatric Pharmacology

Pharmacokinetics

Table 8. Age-Associated Pharmacokinetics

Parameter	Age Effect	Implications
Absorption (less significant)	Increased gastric pH Decreased splanchnic blood flow, GI absorptive surface and dermal vascularity; delayed gastric emptying	Drug-drug and drug-food interactions are more likely to affect absorption
Distribution	Increased total body fat and alpha1-glycoprotein Decreased lean body mass, total body water and albumin	Lipophilic drugs have a larger volume of distribution Decreased binding of acidic drugs, increased binding of basic drugs
Metabolism (less significant)	Decreased hepatic mass and hepatic blood flow; impaired phase I reactions (oxidative system)	Lower doses may be therapeutic
Elimination	Decreased renal blood flow, GFR, tubular secretion and renal mass	For every x% reduction in clearance, decrease the dose by x% and increase the interval by x%

Death Rattle

Noise caused by the oscillatory movement of mucous secretions in the upper airway with inspiration and expiration.

Nociceptive Pain

Somatic: localized to bone/skin/joint/muscle; gnawing, dull pain
Visceral: not well localized; crampy pain, pressure

Neuropathic Pain

Burning, shooting, radiating pain; localized to dermatomal regions

Opioid Equivalent Doses (to 10 mg of IV morphine)

Opioid	SC/IV dose	PO dose
Morphine	10 mg	20-30 mg
Codeine	Not recommended	180-240 mg
Oxycodone	Not recommended	10-15 mg
Hydromorphone	2 mg	4-6 mg

Fentanyl transdermal 25 microgram/hr = morphine 90 mg PO/24 hr, however fentanyl takes 12-16 hours to reach steady state
See *Clinical Pharmacology*, CP14 for complete chart.

Serum creatinine does not reflect creatinine clearance in the elderly.

Instead, use:

$CrCl = \frac{(\text{weight in kg})(140 - \text{age})(1.23)}{(\text{mL/min}) (\text{serum creatinine in } \mu\text{mol/L})}$

Multiply by 0.85 for females.

Benzodiazepines of Choice in the Elderly

LOT

Lorazepam

Oxazepam

Temazepam

Pharmacodynamics

Drug Sensitivity

- changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives and narcotics
- decreased sensitivity to beta-blockers

Decreased Homeostasis

- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

Polypharmacy

Definition

- prescription, administration or use of many medications at the same time

Epidemiology

- in Canada, over 25% of elderly women and about 20% of elderly men reported using ≥ 3 medications
- hospitalized elderly are given an average of 10 medications during admission

Risk Factors for Non-Compliance

- risk of non-compliance correlates with medication factors, not age
 - number of medications – compliance with 1 medication is 80%, but drops to 25% with ≥ 6 medications
 - dosing, frequency
 - labelling, instructions, container design
 - financial constraints – medication cost and coverage (insurance, drug benefit plans)
 - cognitive impairment
 - sensory deprivation

Adverse Drug Reactions (ADRs)

- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in the elderly
 - intrinsic: co-morbidities, age-related changes in pharmacokinetics and pharmacodynamics
 - extrinsic: number of medications, multiple prescribers, unreliable drug history
- 90% of ADRs are from: ASA, other analgesics, anticoagulants, antimicrobials, antineoplastics, digoxin, diuretics, hypoglycemics, steroids

Preventing Polypharmacy

- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical co-morbidities
- consider patient-drug interaction risk factors for ADRs
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an adverse drug reaction with another medication

Inappropriate Prescribing in the Elderly

Epidemiology

- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

Beers Criteria

- examples include long-acting benzodiazepines, strong anticholinergics, high dose sedatives
- the elderly are also often under-treated (ACEI, ASA, beta-blockers, thrombolytics, warfarin)

Approach to Medication Review in the Elderly

NO TEARS

Need and indication

Open-ended questions (to get patient's perspective on medications)

Tests and monitoring (to assess disease control)

Evidence and guidelines

Adverse events

Risk reduction (of adverse events such as falls)

Simplification/switches

Principles for Prescribing in the Elderly

CARE

Caution/Compliance

Age (adjust dosage for age)

Review regimen regularly

Educate

Fordyce, M. *Geriatric Pearls*. Philadelphia: FA Davis Company, 1999.

Adverse drug reactions in the elderly may present as delirium, falls, fractures, urinary incontinence/retention or fecal incontinence/impaction.

Beers Criteria

48 medications to avoid in adults 65 and older due to safety concerns. For full list of medications, consult the following reference:

Fick DM, et al. Updating the Beers Criteria for potentially inappropriate medication use in older adults. *Arch Intern Med* 2003; 163: 2716-2724.

Common Medications

Table 9. Common Medications

Drug Name	Brand Name	Dosing Schedule	Indications	Contraindications	Side Effects	Mechanism of Action
Laxatives						
bran	All-Bran®	1 cup/day	Constipation		Bloating, flatus	Bulk-forming laxative
psyllium	Metamucil® Prodiem Plain®	1 tsp PO tid	Constipation, hypercholesterolemia	N/V, fever, abdo pain, obstruction	Bloating, flatus	Bulk-forming laxative
docusate	Colace® Docusoft®	100 mg PO bid	Constipation	Abdo pain, N/V, fever Not to be used with mineral oil	Mild cramps	Emollient, stool softener
lactulose	Chronulac® Cephulac® Kristalose®	15-30 cc PO daily/bid	Constipation, hepatic encephalopathy, bowel evacuation following barium exam	Patients on low galactose diets Abdo pain, N/V, fever	Flatus, cramps, nausea, diarrhea	Hyperosmolar agent, lowers pH of colon to decrease blood ammonia levels
senna	Senokot®/Ex-lax® Glyssennid®	1-2 tabs PO daily or 10-15 cc syrup PO daily	Constipation	Abdo pain, N/V, fever	Cramps, griping, dependence	Stimulant laxative
bisacodyl	Dulcolax®	5-15 mg PO (10 mg PR)	Constipation	Ileus, obstruction, abdo pain, N/V, fever, severe dehydration	Cramps, pain, diarrhea	Stimulant laxative
Analgesics (non-opioid)						
acetaminophen	Tylenol®	325-650 mg PO q4-6h prn (up to 4 g/day)	Fever, mild pain	Lower doses for hepatic and renal disease, chronic alcoholism, known hypersensitivity	Hepatotoxicity (in overdose)	Prostaglandin-synthesis inhibition, no anti-inflammatory effects
ibuprofen	Advil® Motrin®	200-800 mg PO q4-6h prn (up to 1200 mg/day)	Mild to moderate pain, inflammatory disorders, fever	Active GI bleed/ulcer disease, known hypersensitivity, severe renal or hepatic disease Geriatrics: more susceptible to adverse effects	Dyspepsia, nausea, diarrhea, dizziness, rash, GI toxicity (ulcer, perforation, bleed)	Prostaglandin-synthesis inhibition, anti-inflammatory effects
celecoxib	Celebrex®	OA: 200 mg PO daily or 100 mg PO bid	Osteoarthritis, rheumatoid arthritis, FAP	Cardiovascular or cerebrovascular disease, CABG (peri-op), sulfonamide or ASA/NSAID allergy, active GI bleed/ulcer severe renal or hepatic disease, hyperkalemia disease, IBD, severe renal or hepatic disease, hyperkalemia	GI symptoms (pain, diarrhea, dyspepsia, flatus), GI bleed, serious cardiovascular events	COX-2 inhibitor, analgesic, anti-inflammatory and anti-pyretic effects
Analgesics (opioid) – see Clinical Pharmacology, CP14						
Anti-hypertensives						
thiazide diuretic e.g. hydrochlorothiazide	Hydrazide®	12.5-25 mg PO daily	Hypertension, edema	Anuria, hepatic coma, pre-coma, known sensitivity to thiazides	Hypotension, transient hyperlipidemia, hypokalemia and other electrolyte disturbances, hyperuricemia, GI symptoms	Inhibition of Na/Cl co-transporter
ACEI e.g. ramipril	Altace®	2.5-10 mg PO daily	Essential hypertension, post-MI, cardiovascular disease, renal protection	Known hypersensitivity, angioedema	Hypotension, cough, headache, dizziness, asthenia, chest pain, nausea, peripheral edema, arthritis, dyspnea, angioedema, hyperkalemia	Inhibition of angiotensin-converting enzyme
ARB e.g. losartan	Cozaar®	50-100 mg PO daily	Essential hypertension (± diabetes mellitus)	Known hypersensitivity	Dizziness, hypotension, fatigue, headache, hyperkalemia	Antagonizes angiotensin II via blockade of the angiotensin type 1 receptor
DHP CCB e.g. amlodipine	Norvasc®	2.5-5 mg PO daily (initially)	Essential hypertension, chronic stable angina	Known hypersensitivity, severe hypotension, caution in aortic stenosis	Edema, muscle cramps, dizziness, headache, constipation, heartburn	Calcium ion influx inhibition

Table 9. Common Medications (continued)

Drug Name	Brand Name	Dosing Schedule	Indications	Contraindications	Side Effects	Mechanism of Action
Sleeping Medications						
zopiclone	Imovane® (Canada)	3.75 mg PO qhs (initially)	Insomnia	Known hypersensitivity, caution in myasthenia gravis, severe hepatic disease Geriatrics: dose reduction (dose-related adverse events)	Bitter taste, palpitations, vomiting, anorexia, sialorrhea, confusion, agitation, anxiety, tremor, sweating	Short-acting hypnotic (no tolerance effects)
temazepam	Restoril®	15 mg PO qhs	Short-term management of insomnia	Known hypersensitivity, myasthenia gravis, sleep apnea Geriatrics: dose reduction recommended	Drowsiness, dizziness, impaired coordination, hangover, lethargy, dependence	Benzodiazepine: generalized CNS depression mediated by GABA
lorazepam	Ativan®	0.5 mg PO qhs (initially, then increase)	Anxiety, insomnia	Known hypersensitivity, myasthenia gravis, narrow-angle glaucoma Geriatrics: dose reduction recommended	Dizziness, drowsiness, lethargy, dependence	Benzodiazepine: generalized CNS depression mediated by GABA
Cognitive Enhancers						
donepezil	Aricept®	5-10 mg PO daily	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, caution in pulmonary disease, sick sinus syndrome, seizure disorder	N/V, diarrhea, anorexia	Reversible inhibition of acetylcholinesterase
galantamine	Reminyl®	8-12 mg PO bid	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, caution in sick sinus syndrome, seizure disorder, pulmonary disease, low body weight	N/V, diarrhea, anorexia	Reversible inhibition of acetylcholinesterase
rivastigmine	Exelon®	1.5 mg PO daily (starting) up to 6 mg PO bid	Mild to moderate dementia of Alzheimer's type	Known hypersensitivity, severe hepatic disease, caution in sick sinus syndrome, pulmonary disease, seizure disorder	N/V, diarrhea, anorexia	Acetylcholinesterase inhibition (reversible but very slow)
memantine	Ebixa®/Namenda® (Cdn)/US	5 mg PO daily (starting) up to 10 mg PO bid	Moderate to severe dementia of Alzheimer's type	Known hypersensitivity, conditions that alkalize urine, caution in cardiovascular conditions	Agitation, fatigue, dizziness, headache, hypertension, constipation	NMDA-receptor antagonist

Parkinsonian Agents – see [Neurology, N27](#)

Basic Anatomy Review

A. EXTERNAL GENITALIA (Figure 1)

- referred to collectively as the vulva
- blood supply: internal pudendal artery
- sensory innervation: pudendal nerve
- lymphatic drainage: inguinal nodes

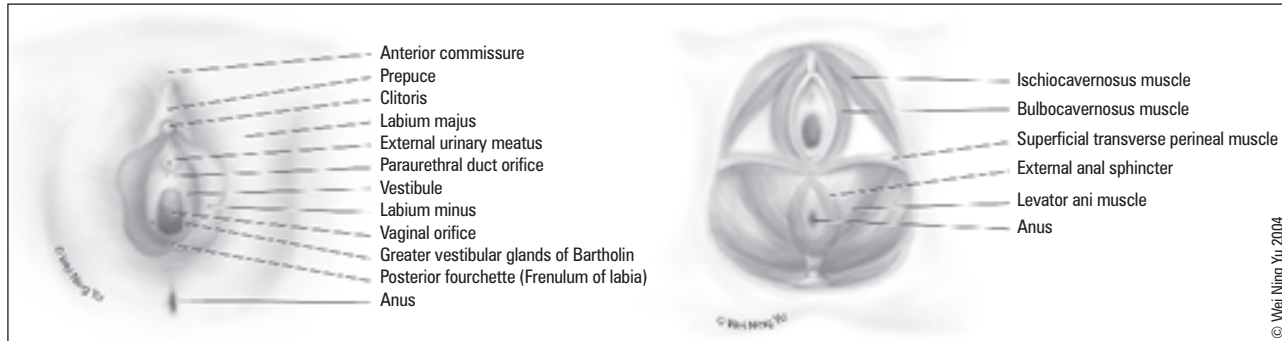

Figure 1. Vulva and Perineum

B. VAGINA

- muscular canal extending from cervix to vulva, anterior to rectum and posterior to bladder
- lined by rugated, stratified-squamous epithelium
- upper vagina separated by cervix into anterior, posterior and lateral fornices
- blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical and middle rectal arteries

C. UTERUS

- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
 - uterine corpus
 - ♦ blood supply: uterine artery (branch of the internal iliac artery)
 - cervix
 - ♦ blood supply: cervical branch of uterine artery
- position (Figure 2)
 - anteverted (majority)
 - retroverted
- supported by the pelvic diaphragm, the pelvic organs and 4 paired sets of ligaments
 - round ligaments: travel from anterior surface of uterus, through broad ligaments, through inguinal canals then terminate in the labia majora
 - ♦ function: anteversion
 - ♦ blood supply: Sampson's artery (branch of uterine artery running through round ligament)
 - uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
 - ♦ function: mechanical support for uterus and contain autonomic nerve fibres
 - cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
 - ♦ function: mechanical support, prevents prolapse
 - broad ligaments: pass from lateral pelvic wall to sides of uterus; contains fallopian tube, round ligament, ovarian ligament, nerves, vessels and lymphatics
- infundibulopelvic ligament: continuous tissue that connects ovary to pelvic wall
 - contains the ovarian artery, ovarian vein, ovarian plexus, lymphatic vessels

Anteversion: forward tilted uterus

Anteflexion: bending of uterus so the fundus is thrust forward

Retroversion: backward tilted uterus

Retroflexion: bending of uterus so the fundus is thrust backward

Figure 2. Positioning of Uterus

Figure 3. Internal Genital Organs

D. FALLOPIAN TUBES

- 8-14 cm muscular tubes extending laterally from the uterus to ovary
- interstitial, isthmic, ampullary and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

E. OVARIES

- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

Figure 4. Vascular Supply

Menstruation

Stages of Puberty

- see Pediatrics, P17
- adrenarche: increase in secretion of adrenal androgens; usually precedes gonadarche by 2 years
- gonadarche: increased secretion of gonadal sex steroids; ~age 8
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 years following breast budding

The ureters run posterior to the uterine arteries
Water under the bridge

Stages of Puberty
Boobs, Pubes, Grow, Flow
"Thelarche, Pubarche, Growth spurt, Menarche"

Tanner Stage
Thelarche
I. None
II. Breast bud
III. Further enlargement of areola and breasts with no separation of their contours
IV. 2nd mound of areola and papilla
V. Areola recessed to general contour of breast = adult

Pubarche
I. None
II. Downy hair along labia only
III. Darker/coarse hair extends over pubis
IV. Adult type covers smaller area, no thigh involvement
V. Adult hair in quantity and type and extends over thighs

Menstrual Cycle

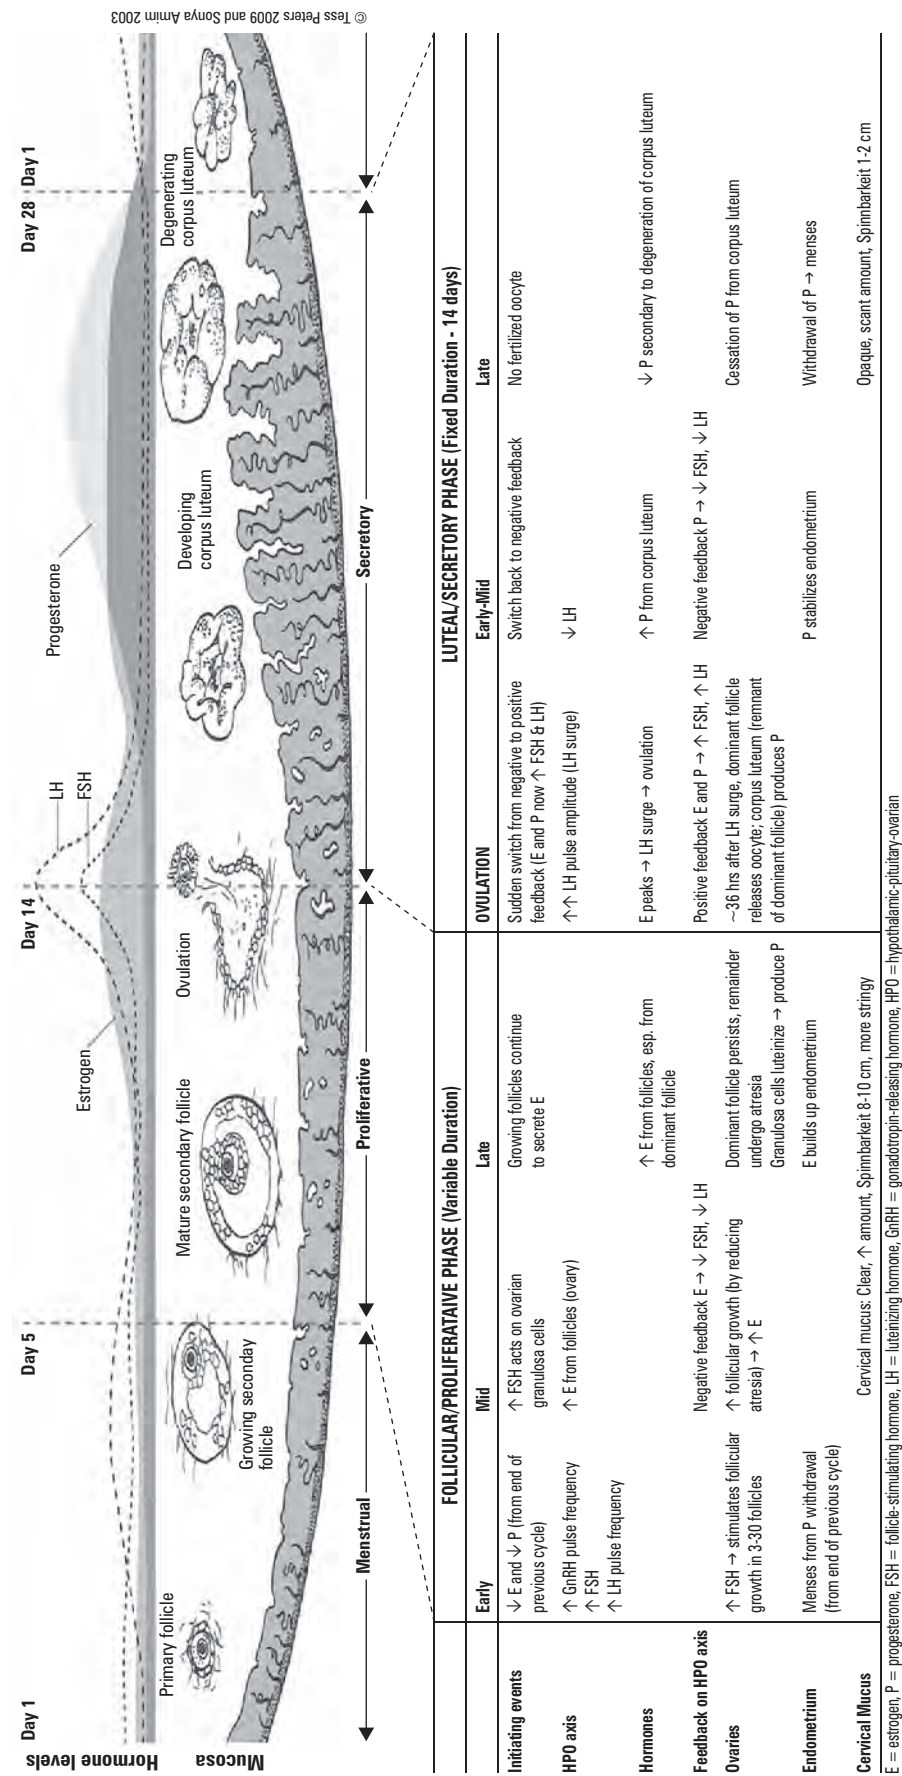

Figure 5. Events of the Normal Menstrual Cycle

Characteristics

- Menarche 10-15 years
- Average 12.2 years
- Entire cycle 28 ± 7 days with bleeding for 1-6 days
- 25-80 mL blood loss per cycle

Estrogen

ESTROGEN is the main hormone in the follicular/proliferative phase. Stimulated by LH. Estrogen mainly decreases FSH. The majority of estrogen is secreted by the dominant follicle.

Estrogen effects:

- On the follicles in the ovaries:
 - Reduces atresia
- On the endometrium:
 - Proliferation of glandular and stromal tissue
- On all target tissues:
 - Decreases E receptors

Progesterone

PROGESTERONE is the main hormone in the luteal/secretory phase stimulated by LH. Progesterone mainly decreases LH and is secreted by the corpus luteum (remnant of dominant follicle).

Progesterone effects:

- On the endometrium:
 - cessation of mitoses (stops building endometrium up)
 - "organization" of glands (initiates secretions from glands)
 - inhibits macrophages, interleukin-8 and enzymes from degrading endometrium
- On all target tissues:
 - decreased E receptors (the "anti-estrogen" effect)
 - decreased P receptors

Premenstrual Syndrome (PMS)

- synonyms: “ovarian cycle syndrome,” “menstrual molimina” (moodiness)

Etiology

- not completely understood, multifactorial, genetics likely play a role
- CNS-mediated neurotransmitter interactions with sex steroids (progesterone, estrogen and testosterone)
- serotonergic dysregulation – currently most plausible theory

Diagnostic Criteria for Premenstrual Syndrome

- at least one of the following affective and somatic symptoms during the 5 days before menses in each of the three prior menstrual cycles
 - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
 - somatic: breast tenderness, abdominal bloating, headache, swelling of extremities
- symptoms relieved within 4 days of onset of menses
- symptoms present in the absence of any pharmacologic therapy, drug or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or economic performance

Treatment

- goal: symptom relief
- psychological support
- diet/supplements
 - avoid sodium, simple sugars, caffeine and alcohol
 - calcium (1200-1600 mg/d), magnesium (400-800 mg/d), vitamin E (400 IU/d), vitamin B₆
- medications
 - NSAIDs for discomfort, pain
 - spironolactone for fluid retention: used during luteal phase
 - SSRI antidepressants: used during luteal phase x 14 days or continuously
 - progesterone suppositories
 - OCP: primarily beneficial for physical/somatic symptoms
 - danazol: an androgen that inhibits pituitary-ovarian axis
 - GnRH agonists if severe PMS unresponsive to other treatment
- mind/body approaches
 - regular aerobic exercise
 - cognitive behavioural therapy
 - relaxation, light therapy biofeedback and guided imagery
- herbal remedies (variable evidence)
 - evening primrose oil, black cohosh, St. John's wort, kava, ginkgo

Premenstrual Syndrome

Physiological and emotional disturbances which generally occur 1-2 weeks preceding menses until a few days after onset of menses. Common symptoms include depression, irritability, tearfulness and mood swings.

Premenstrual Dysphoric Disorder (PMDD)

Definition

- official diagnosis in the DSM-IV-TR
- described as a more severe form of PMS with specific diagnostic criteria
- treatment with SSRIs (first line), and Yaz® OCP (highly effective)
- see [Psychiatry](#), PS11

Differential Diagnoses of Common Presentations

Abnormal Uterine Bleeding (AUB)

- see *Disorders of Menstruation*, GY13
- definition: change in frequency, duration or amount of menstrual flow
- classified as amenorrhea, oligomenorrhea, menorrhagia/hyperménorrhagia, hypomenorrhea, metrorrhagia, menometrorrhagia, polymenorrhea, postmenopausal bleeding
 - hypomenorrhea: bleeding that is decreased in amount
 - polymenorrhea: bleeding occurring at intervals <21 days
 - menorrhagia/hyperménorrhagia: bleeding at regular intervals that is prolonged in duration (>7 days) or excessive in amount (>80 cc per menstrual cycle)
 - metrorrhagia: bleeding at irregular intervals, particularly between expected menstrual periods
 - menometrorrhagia: excessive bleeding at usual time of menstrual periods and at other irregular intervals
 - postmenopausal bleeding: any bleeding that presents >1 year after menopause; endometrial cancer until proven otherwise

Dysmenorrhea

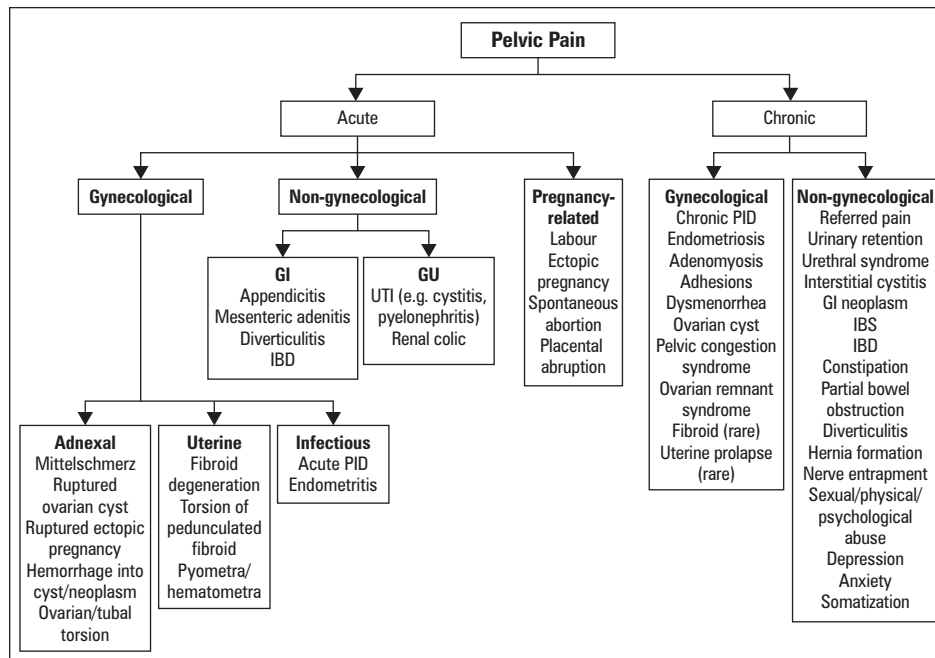

Dysmenorrhea
Painful menstruation.

- see *Disorders of Menstruation*, GY12
- primary/idiopathic
- secondary (acquired)
 - endometriosis
 - adenomyosis
 - uterine polyps
 - uterine anomalies (e.g. non-communicating uterine horn)
 - leiomyoma
 - intrauterine synechiae
 - ovarian cysts
 - cervical stenosis
 - imperforate hymen, transverse vaginal septum
 - pelvic inflammatory disease (PID)
 - IUD – copper
 - foreign body

Vaginal Discharge/Pruritus

- see *Gynecological Infections*, GY24
- physiologic discharge and cervical mucus production
- non-physiologic
 - genital tract infection
 - vulvovaginitis: candidiasis, trichomoniasis, bacterial vaginosis (BV), polymicrobial superficial infection
 - chlamydia, gonorrhea
 - pyosalpinx, salpingitis
 - genital tract inflammation (non-infectious)
 - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
 - neoplasia: vulvar, vaginal, cervical, endometrial
 - systemic: toxic shock syndrome, Crohn's disease, collagen disease, dermatologic (e.g. lichen sclerosis)
 - IUD, OCP (secondary to progesterone)

Pelvic Pain

Chronic Pelvic Pain (CPP)
Intermittent or constant pain of
> 6 months duration.

20% of CPP patients have a history of
previous sexual abuse/assault.
(remember to ask about it!)

Pyometra
Pus within the uterine cavity.

Hematometra
Blood within the uterine cavity.

Figure 6. Approach to Pelvic Pain

Pelvic Mass

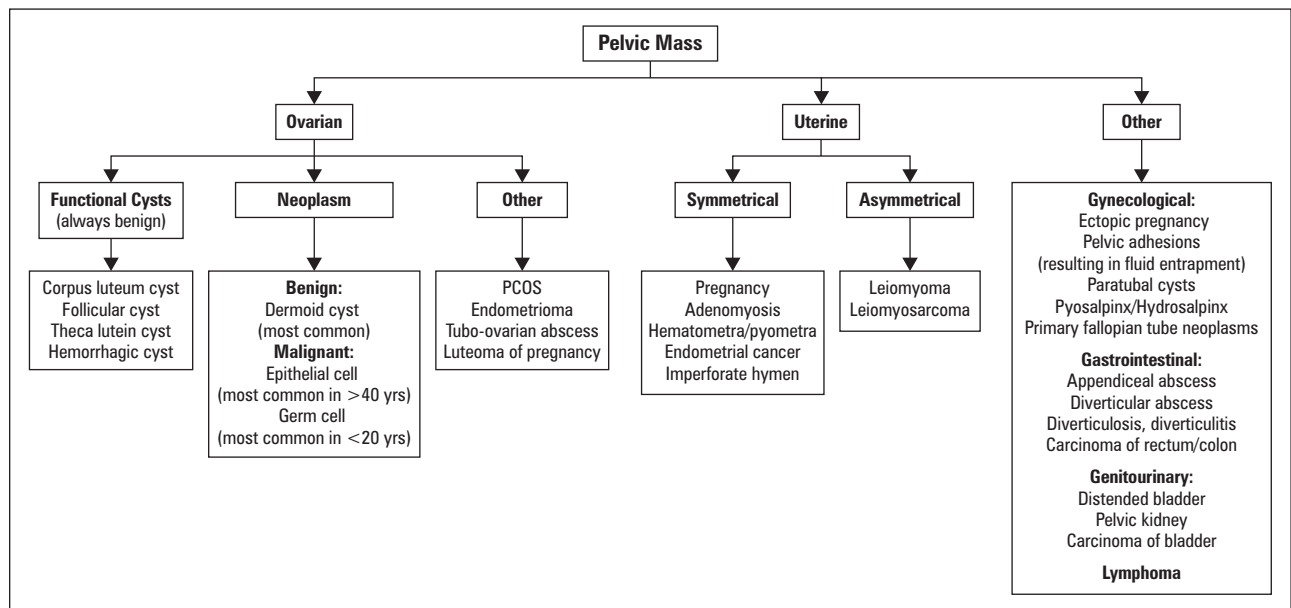

Figure 7. Differential Diagnosis of Pelvic Mass

Dyspareunia

Dyspareunia
Painful intercourse.

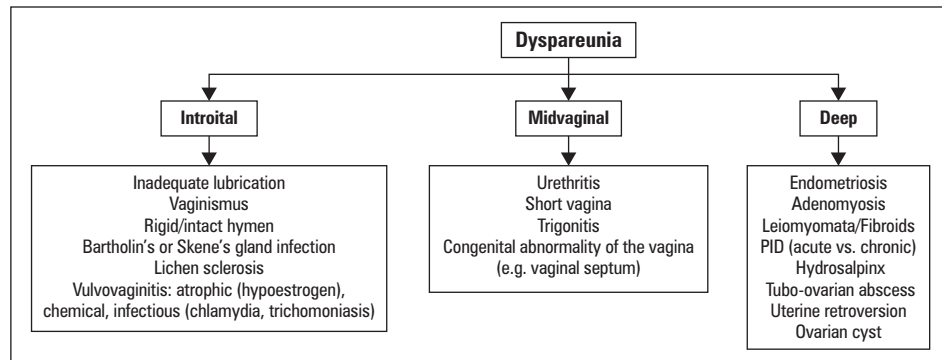

Figure 8. Approach to Dyspareunia

Common Investigations

Bloodwork

- CBC
 - evaluation of severity of abnormal uterine bleeding, pre-op investigation \pm ferritin if anemic
- beta-hCG
 - investigation of possible pregnancy, ectopic pregnancy, ovarian germ cell tumour
 - work-up for gestational trophoblastic disease/neoplasia (GTD/GTN)
 - monitored after medical management of ectopic pregnancy and GTN to assess for cure or recurrence
- LH, FSH, TSH, free T_4 , PRL, DHEA, testosterone, estradiol, androstenedione
 - investigation of amenorrhea, menstrual irregularities, menopause, infertility

Imaging

Ultrasound (U/S)

- transabdominal or transvaginal U/S is imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
 - detects early pregnancy if beta-hCG ≥ 1500 (beta-hCG must be ≥ 6500 for transabdominal U/S)
- may be used to identify pelvic pathology
 - identify ectopic pregnancy, intrauterine pregnancy
 - assess uterine, adnexal, cul-de-sac, ovarian masses (e.g. solid or cystic)
 - determine endometrial thickness, locate/characterize fibroids
 - monitor follicles during assisted reproduction

Sonohysterography (SHG)

- saline infusion into endometrial cavity expands endometrial cavity, improving visualization of uterus and fallopian tubes
- useful for investigation of
 - abnormal uterine bleeding (AUB)
 - uncertain endometrial findings on transvaginal U/S
 - infertility (tubal patency)
 - congenital/acquired uterine abnormalities (e.g. fibroids, endometrial polyps)
- easily done, minimal cost, well-tolerated, sensitive and specific
- frequently avoids need for diagnostic hysteroscopy

Hysterosalpingography (HSG)

- x-ray contrast introduced through the cervix into the uterus
- used for evaluation of size, shape, configuration of uterus, congenital uterine abnormalities, tubal patency, or obstruction
- useful for investigation of infertility

Check for STIs before performing SHG and HSG to prevent PID in high-risk individuals.

Common Procedures

Genital Tract Biopsy

Vulvar Biopsy

- performed under local anesthetic
- Keyes/punch biopsy
- hemostasis achieved with local pressure and Monsel's solution (ferric sulfate), silver nitrate or suture (rarely)

Vaginal Biopsy and Cervical Biopsy

- anesthetic not necessary
- punch biopsy or biopsy forceps
- hemostasis with Monsel's solution and pressure

Endometrial Biopsy

- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
 - pre-treatment with misoprostol (Cytotec®) if nulliparous or postmenopausal
- more invasive procedure (D&C) may be done in the office or operating room ± hysteroscopy

Colposcopy

- **diagnostic use**
 - magnifies surface structures of the vulva, vagina, cervix and perianal region
 - 1% acetic acid wash applied to cervix dehydrates cells and reveals "acetowhite" areas that correspond to increased nucleus-to-cytoplasm ratio (abnormal)
 - allows biopsy of acetowhite lesions for early identification of dysplasia and cancer
- **therapeutic use**
 - cryotherapy: nitrous oxide or carbon dioxide freezes dysplastic lesions, genital warts
 - laser vaporization: used to treat dysplastic lesions of the exocervix and benign ectropion
 - loop electrosurgical excision procedure (LEEP): excision of transformation zone with the cervical lesion; provides a specimen for pathological examination

Dilatation and Curettage (D&C)

- prior to procedure, determine depth with uterine sound
- dilatation of cervix with dilators of increasing diameter
- scrape entire uterine cavity with sharp curette
- anesthesia: general or local

Indications

- diagnostic (rarely done without hysteroscopy)
 - abnormal uterine bleeding (AUB)
 - dysfunctional uterine bleeding (DUB)
- therapeutic
 - removal of retained products of conception following abortion
 - termination of pregnancy in 1st trimester
 - removal of small uterine polyps or pedunculated submucosal fibroids

Complications

- bleeding
- infection
- perforation of uterus, laceration of cervix
 - reduce risk with preoperative misoprostol (Cytotec®) inserted per vagina to soften cervix and stimulate uterine contraction
- incompetent cervix – extremely rare

Laparoscopy

- laparoscope (fiber optic camera) used to view pelvic/abdominal contents through small incisions

Indications

- diagnostic
 - evaluation of infertility, pelvic pain, pelvic masses, congenital anomalies, hemoperitoneum and endometriosis
- therapeutic
 - tubal ligation
 - lysis of adhesions
 - excision of ectopic pregnancy
 - excision/ablation of endometriosis
 - retrieval of lost IUDs
 - cystectomy, salpingo-oophorectomy and hysterectomy
 - myomectomy
 - treatment of stress urinary incontinence

Contraindications

- bowel obstruction
- large hemoperitoneum
- clinically unstable patient
- inability to maintain pneumoperitoneum
- multiple previous abdominal surgeries (i.e. adhesions)

Complications

- general anesthetic
- insufflation of the preperitoneal abdominal wall
- injury to vascular structures (e.g. aorta, inferior epigastric vessels)
- injury to viscous (bowel, bladder, ureters)
- may need to convert to laparotomy
- infection

Hysteroscopy

- flexible or rigid scope inserted through cervix into uterus to visualize uterine cavity
- distension medium is used to allow inspection of this potential space

Indications

- diagnostic
 - detection of uterine anomalies or pathology (e.g. infertility work-up)
 - AUB
 - DUB
- therapeutic
 - removal of uterine polyps, fibroids, adhesions, septums
 - endometrial ablation

Complications

- perforation of uterus, laceration of cervix
- bleeding
- infection
- absorption of excess distension medium (when sugar solutions utilized)
 - fluid overload, hyponatremia
 - procedure should be abandoned if the fluid deficit rises to 1L; consider stopping at 500 cc
- air emboli
- anaphylactic shock

Endometrial Ablation

- alternative invasive procedure to hysterectomy for treatment of AUB; performed as outpatient
- rationale is to coagulate or resect the endometrium basalis layer to prevent monthly build-up and reduce menstrual losses

Methods

- rollerball electrode coagulation or resection
- microwave endometrial ablation
- thermoablation (hot water), balloon ablation
- laser photocoagulation

Complications

- infection
- injury to pelvic viscera if perforated uterus
- hematometra
- absorption of excess distention medium → fluid overload, hyponatremia
- failure (i.e. bleeding/menorrhagia persists)
- may eventually require hysterectomy for recurrence of symptoms (~20% at 5 years)

Hysterectomy

Indications

- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervical)

Complications

- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)

Approaches

1. vaginal vs. abdominal
 - indications for vaginal approach: mobile uterus, uterine size <12 weeks
 - advantages of vaginal approach: less pain, faster recovery time, allows for simultaneous repair of rectocele/cystocele/enterocele, improved esthetics
2. open vs. laparoscopic-assisted
 - advantages of laparoscopy: less pain, faster recovery, improved esthetics, shorter hospital stay

Approaches to Hysterectomy

Abdominal hysterectomy: uterus removed via transverse or vertical laparotomy.

Vaginal hysterectomy: uterus removed via vagina. No visualization or entry into abdomen unless laparoscopic-assisted.

Table 1. Classification of Hysterectomy

Classification	Tissues Removed	Indications
Subtotal hysterectomy	Uterus	Inaccessible cervix (e.g. adhesions) Patient choice/preference
Total hysterectomy	Uterus, cervix	Uterine fibroids Endometriosis Adenomyosis Menorrhagia DUB
Total hysterectomy + bilateral salpingo-oophorectomy (TH/BSO)	Uterus, cervix, fallopian tubes, ovaries	Endometrial cancer Benign or malignant adnexal masses >45 years old Consider for endometriosis
Radical hysterectomy	Uterus, cervix, fallopian tubes, ovaries, broad ligaments, parametria, upper half of vagina, regional lymph nodes	Cervical cancer (up to stage IBI, see Table 17)

Disorders of Menstruation

Amenorrhea

Primary Amenorrhea

No menses by age 14 in absence of 2° sexual characteristics or no menses by age 16 with 2° sexual characteristics.

Secondary Amenorrhea

No menses for >6 months or 3 cycles after documented menarche.

Oligomenorrhea

Episodic vaginal bleeding occurring at intervals >35 days.

2° amenorrhea is pregnancy until proven otherwise.

Prolactinoma Symptoms

Galactorrhea, visual changes, headache.

Etiology

- see *Differential Diagnoses of Common Presentations*, GY6

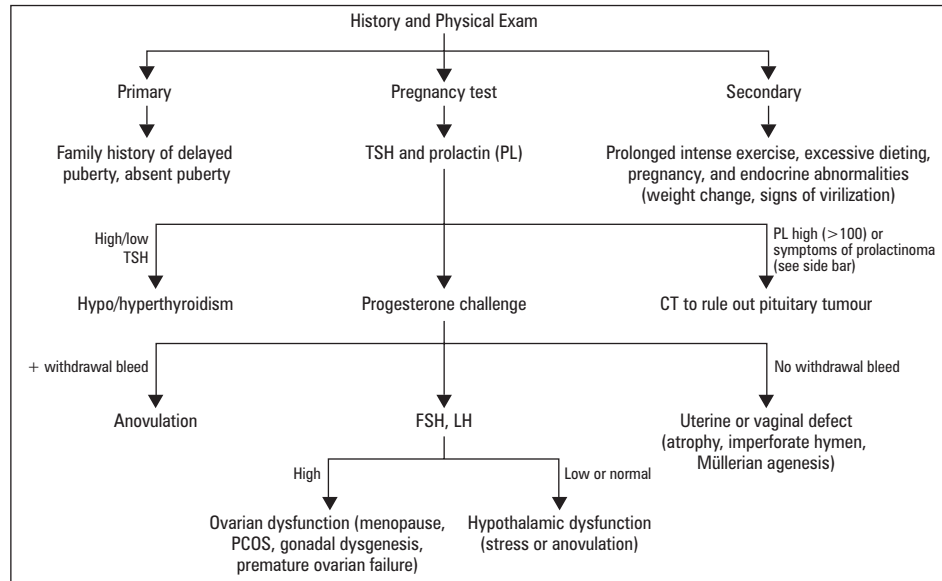

Figure 9. Diagnostic Approach to Amenorrhea

Investigations (see Figure 9)

- beta-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
 - medroxyprogesterone acetate (Provera®) 10 mg PO OD for 10 days
 - any uterine bleed within 2-7 days after completion of Provera® is considered to be a positive test/withdrawal bleed
 - ♦ withdrawal bleed suggests presence of adequate estrogen to thicken the endometrium; thus withdrawal of progesterone results in bleeding
 - ♦ if no bleeding occurs, there may be inadequate estrogen (hypoestrogenism) or excessive androgens
- karyotype if indicated (if premature ovarian failure or absent puberty)
- U/S to confirm normal anatomy, identify PCOS

Treatment

- **hypothalamic dysfunction (low or normal FSH, LH)**
 - if low FSH/LH, consider head imaging (CT or MRI) if no other obvious etiology
 - stop any medications, reduce stress, adequate nutrition, decrease excessive exercise
 - if pregnancy desired, correct underlying problem; but may require gonadotropins to stimulate ovulation
 - otherwise OCP to induce menstruation (withdrawal bleed) – may not prevent other manifestations of hypoestrogenic state, e.g. bone loss
- **hyperprolactinemia**
 - consider CT of head to document presence of pituitary micro/macroadenoma
 - surgery for macroadenoma (rarely)
 - bromocriptine if fertility desired; OCP if fertility not desired
- **premature ovarian failure (high FSH, LH)**
 - karyotype
 - removal of gonadal tissue if Y chromosome present (at 18 years or earlier if dysgenic gonads)
 - HRT or OCP to prevent manifestations of hypoestrogenic state
- treat associated autoimmune disorders (thyroid, adrenal)
- **PCOS**
 - see *Polycystic Ovarian Syndrome*, GY23

Abnormal Uterine Bleeding (AUB)

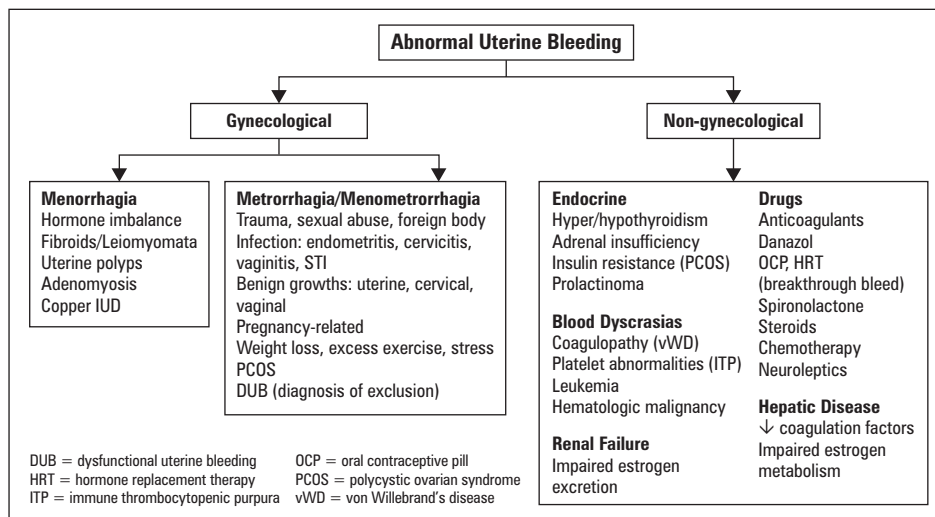

Figure 10. Approach to Abnormal Uterine Bleeding

Table 2. Comparison of Anovulatory and Ovulatory Abnormal Uterine Bleeding

	Anovulatory	Ovulatory
Incidence	90%	10%
Definition	Unpredictable endometrial bleeding of variable flow and duration; sex steroids are produced but not cyclically, resulting in irregular bleeding	Typically cyclic, but heavy or prolonged
Etiology	PCOS Thyroid dysfunction Elevated prolactin levels Rare estrogen-producing tumours Stress, weight loss, exercise Liver and kidney disease	Anatomic or physical lesion (e.g. polyp, fibroid, adenomyosis, neoplasm, foreign body) Hemostatic defect Infection; trauma Local disturbances in prostaglandins (elevated endometrial vasodilatory prostaglandins, decreased vasoconstrictive prostaglandin)
Pathophysiology	Estrogen dependent breakthrough bleeding: chronic estrogen production unopposed by adequate progesterone production → continued proliferation of the endometrium → thickened endometrium outgrows its blood supply → focal necrosis with partial shedding not uniformly → bleeding is usually irregular, prolonged, and heavy	Depends on underlying etiology

Investigations

- CBC, serum ferritin
- beta-hCG
- TSH, free T₄
- coagulation profile (esp. adolescent): rule out von Willebrand's disease
- prolactin if amenorrheic
- FSH, LH
- serum androgens (especially free testosterone)
- day 21 (luteal phase) progesterone to confirm ovulation
- Pap test
- pelvic U/S: detect polyps, fibroids; measure endometrial thickness (postmenopausal)
- SHG: very sensitive for intrauterine pathology (polyps, submucous fibroids)
- HSG
- endometrial biopsy: women >40 years are at higher risk of endometrial cancer
 - must do endometrial biopsy in **all** women presenting with postmenopausal bleeding to exclude endometrial cancer
- D&C: not for treatment; diagnosis only (usually with hysteroscopy)

Dysfunctional Uterine Bleeding

Abnormal bleeding not attributable to organic (anatomic/systemic) disease. DUB is a diagnosis of exclusion. Anovulatory AUB often used synonymously with DUB.

Treatment

- treat underlying disorders:
 - if anatomic lesions and systemic disease have been ruled out, consider dysfunctional uterine bleeding (DUB)
- medical
 - mild DUB (see sidebar)
 - ♦ NSAIDs
 - ♦ anti-fibrinolytic (e.g. Cyklokapron®) at time of menses
 - ♦ combined OCP
 - ♦ progestins (Provera®) on first 10-14 days of each month if oligomenorrheic
 - ♦ Mirena® IUD
 - ♦ danazol
 - acute, severe DUB
 - ♦ replace fluid losses, consider admission
 - ♦ medical treatment
 - a) estrogen (Premarin®) 25 mg IV q4h x 24h with Gravol® 50 mg IV/PO q4h or
 - b) Ovral® 1 tab PO q4h x 24h with Gravol® 50 mg IV/PO q4h
 - taper Ovral®: 1 tab tid x 2d → bid x 2d → OD
 - ♦ after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
 - clomiphene citrate
 - ♦ consider in patients who are anovulatory and who wish to get pregnant
- surgical
 - endometrial ablation; consider pretreatment with danazol or GnRH agonists
 - ♦ if finished childbearing
 - ♦ repeat procedure may be required if symptom recurrence
 - hysterectomy: definitive treatment

Dysmenorrhea

Etiology

- see *Differential Diagnoses of Common Presentations*, GY6

Table 3. Comparison of Primary and Secondary Dysmenorrhea

	Primary Dysmenorrhea	Secondary Dysmenorrhea
Features	Menstrual pain in absence of organic disease Begins 6 months-2 years after menarche (once ovulatory cycles established)	Menstrual pain due to organic disease Usually begins in women who are in their 20s, worsens with age May improve temporarily after childbirth
Signs and Symptoms	Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: nausea, vomiting, altered bowel habits, headaches, fatigue [prostaglandin (PG)-associated]	Associated dyspareunia, abnormal bleeding, infertility
Diagnosis	Associated dyspareunia, abnormal bleeding, infertility Rule out underlying pelvic pathology and confirm cyclic nature of pain	Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus U/S, laparoscopy and hysteroscopy may be necessary to establish the diagnosis
Treatment	PG synthetase inhibitors (e.g. Anaprox®) • Should be started before onset of pain OCP: suppress ovulation/reduce menstrual flow	Treat underlying cause

Primary Dysmenorrhea

Menstrual pain in absence of organic disease.

Secondary Dysmenorrhea

Menstrual pain due to organic disease.

Endometriosis

Etiology

- not fully understood
- proposed mechanisms (combination likely involved)
 - retrograde menstruation (Sampson's theory)
 - ♦ seeding of endometrial cells by transtubal regurgitation during menstruation
 - ♦ endometrial cells most often found in dependent sites of the pelvis
 - immunologic theory: altered immunity may limit clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
 - metaplasia of coelomic epithelium
 - ♦ undefined endogenous biochemical factor may induce undifferentiated peritoneal cells to develop into endometrial tissue
 - extrapelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
 - ♦ e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

Epidemiology

- incidence: 15-30% of pre-menopausal women
- mean age at presentation: 25-30 years
- regresses after menopause

Risk Factors

- family history (7-10 fold increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset)
- nulliparity
- age >25 years

Sites of Occurrence

- ovaries: 60% patients have ovarian involvement
- broad ligament, vesicoperitoneal fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs

Clinical Features

- may be asymptomatic
- history
 - menstrual symptoms
 - ♦ cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 hrs) and continue throughout and after flow
 - ♦ secondary dysmenorrhea
 - ♦ sacral backache with menses
 - ♦ pain may eventually become chronic, worsening perimenstrually
 - ♦ premenstrual and postmenstrual spotting
 - ♦ deep dyspareunia
 - infertility
 - ♦ 30-40% of patients with endometriosis will be infertile
 - ♦ 15-30% of those who are infertile will have endometriosis
 - bowel and bladder symptoms
 - ♦ frequency, dysuria, hematuria
 - ♦ diarrhea, constipation, hematochezia, dyschezia
- physical
 - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
 - fixed retroversion of uterus
 - firm, fixed adnexal mass (endometrioma)
 - physical findings not present in adolescent population

Investigations

- definitive diagnosis requires:
 - direct visualization of lesions typical of endometriosis at laparoscopy
 - biopsy and histologic exam of specimens (2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages)
- laparoscopy
 - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac or anywhere in the pelvis
 - endometrioma: "chocolate" cysts on the ovaries
 - "powder-burn" lesions on the peritoneal surface
 - early white lesions and clear blebs
 - peritoneal "pockets"
- CA-125
 - may be elevated in patients with endometriosis

Endometriosis

The presence of endometrial tissue (glands and stroma) outside of the uterine cavity.

Differential Diagnosis

1. Chronic PID, recurrent acute salpingitis
2. Hemorrhagic corpus luteum
3. Benign/malignant ovarian neoplasm
4. Ectopic pregnancy

Endometrioma = endometriotic cyst on surface of ovary.

There may be little correlation between the extent of endometriosis and symptomatology.

Classic Triad of Endometriosis

- Dysmenorrhea
- Dyspareunia (cul de sac, uterosacral ligament)
- Dyschezia (uterosacral ligament, cul-de-sac, rectosigmoid attachment)

A sharp, firm, and exquisitely tender "barb" on the uterosacral ligament is a classic feature of endometriosis.

Endometriosis is classified according to a scoring system standardized by the American Society for Reproductive Medicine. Score is based on location and extent of disease.

Recurrence Rates
Medical therapy: 30-50%
Conservative surgery: 14-40%

Treatment

- depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility and impact to GI/GU systems (e.g. intestinal obstruction)
- **medical**
 - NSAIDs – e.g. naproxen sodium (Anaprox®)
 - pseudopregnancy
 - ♦ cyclic/continuous estrogen-progestin (OCP)
 - ♦ medroxyprogesterone (Depo-Provera®)
 - pseudomenopause
 - ♦ 2nd line: only short-term (<6 months) due to osteoporotic potential with prolonged use, unless add-back therapy (e.g. estrogen/progesterone or SERM)
 - ♦ danazol (Danocrine®) = weak androgen
 - side effects: weight gain, fluid retention, acne, hirsutism, voice change
 - ♦ leuprolide (Lupron®) = GnRH agonist (suppresses pituitary)
 - side effects: hot flashes, vaginal dryness, reduced libido
 - can use ≥12 months with add-back progestin or estrogen
- **surgical**
 - conservative laparoscopy using laser, electrocautery ± laparotomy
 - ♦ ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
 - definitive: bilateral salpingo-oophorectomy ± hysterectomy
 - ± follow-up with medical treatment for pain control NOT shown to impact on preservation of fertility
 - best time to become pregnant is immediately after conservative surgery

Adenomyosis

Adenomyosis

Extension of areas of endometrial glands and stroma into the myometrium.

- synonym: “endometriosis interna” (uterine wall may be diffusely involved)

Epidemiology

- 15% of females >35 years old; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 years old (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

Clinical Features

- often asymptomatic
- menorrhagia, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm, mobility not restricted, no associated adnexal pathology
- Halban sign: tender, softened uterus on premenstrual bimanual exam

Investigations

- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

Treatment

- iron supplements as necessary
- analgesics, NSAIDs
- OCP, Depo-Provera® (medroxyprogesterone)
- low dose danazol 100-200 mg PO OD (trial x 4 months)
- GnRH agonists (e.g. leuprolide)
- definitive: hysterectomy (no conservative surgical treatment)

Leiomyomata (Fibroids)

Leiomyomata/Fibroids

Benign smooth muscle tumour of the uterus (most common gynecological tumour).

Epidemiology

- diagnosed in approximately 40-50% of reproductive age women >35 years
- more common, larger and occur at earlier age in black women
- common indication for major surgery in females
- minimal malignant potential (1:1000)
- typically regress after menopause; enlarging fibroids in a postmenopausal woman should prompt consideration of malignancy

Pathogenesis

- estrogen stimulates monoclonal smooth muscle proliferation; progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
 - hyaline degeneration (most common degenerative change)
 - cystic degeneration (from breakdown of hyaline)
 - red/carneous degeneration (hemorrhage into tumour, may occur in pregnancy)
 - fatty degeneration
 - calcification
 - sarcomatous degeneration (rare)
 - parasitic myoma: tumour becomes attached to another organ (typically omentum or small bowel mesentery), develops new blood supply and loses connection to uterus

Clinical Features

- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S
- abnormal uterine bleeding (30%): dysmenorrhea, menorrhagia
- pressure/bulk symptoms (20-50%)
 - pelvic pressure/heaviness
 - increased abdominal girth
 - urinary frequency and urgency
 - acute urinary retention (extremely rare but surgical emergency!)
 - constipation, bloating (rare)
- acute pelvic pain
 - fibroid degeneration
 - fibroid torsion (pedunculated subserosal)
- infertility (submucosal), recurrent pregnancy loss
- pregnancy complications (potential enlargement and increased pain, obstructed labour, difficult C-section)

Investigations

- bimanual exam: uterus asymmetrically enlarged, usually mobile
- CBC: anemia
- ultrasound: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids
- endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if age >40 years)
- occasionally MRI is used for pre-op planning (e.g. before myomectomy)

Treatment

- only if symptomatic, rapidly enlarging or menorrhagia
- treat anemia if present
- conservative approach (watch and wait)
 - symptoms absent or minimal
 - fibroids <6-8 cm or stable in size
 - not submucosal (submucosal fibroids are more likely to be symptomatic)
 - currently pregnant due to increased risk of bleeding (follow-up U/S if symptoms progress)
- medical approach
 - antiprostaglandins (ibuprofen, other NSAIDs)
 - tranexamic acid (Cyklokapron®)
 - OCP/Depo-Provera®
 - GnRH agonist: leuprolide (Lupron®), danazol (Danocrine®)
 - short-term use only (6 months)
 - often used pre-myomectomy or pre-hysterectomy to reduce fibroid size
- interventional radiology approach
 - uterine artery embolization occludes both uterine arteries → shrinks fibroids by 50% at 6 months; improves menorrhagia in 90% of patients within 1-2 months; not an option in women considering childbearing
- surgical approach
 - myomectomy (hysteroscopic, transabdominal or laparoscopic): preserves fertility
 - endometrial resection of fibroid and endometrial ablation for menorrhagia
 - hysterectomy (see GY11)
 - note:** avoid operating on fibroids during pregnancy (due to ++ vascularity and potential pregnancy loss); expectant management usually best

Figure 11. Possible Anatomic Locations of Uterine Leiomyomata

Submucosal leiomyomata are most symptomatic (bleeding, infertility).

Even with known fibroids, abnormal uterine bleeding + age >40 yrs – always do endometrial biopsy to rule out cancer.

Contraception

- see [Family Medicine](#), FM19

Table 4. Classification of Contraceptive Methods

Type	Effectiveness (perfect use, typical use)
Physiological	
Withdrawal/coitus interruptus	77.0%
Rhythm method/calendar/mucous/symptothermal	98.0%, 76.0%
Lactational amenorrhea	98% (first 6 months postpartum)
Chance – no method used	10.0%
Abstinence of all sexual activity	100.0%
Barrier Methods	
Condom alone	98.0%, 85.0%
Spermicide alone	82.0%, 71.0%
Sponge – Parous	80.0%, 68.0%
– Nulliparous	91.0%, 84.0%
Diaphragm with spermicide	94.0%, 84.0%
Female condom	95.0%, 79.0%
Cervical cap – Parous	74.0%, 68.0%
– Nulliparous	91.0%, 84.0%
Hormonal	
OCP	99.7%, 92.0%
Nuvaring	99.7%, 92.0%
Transdermal (Ortho Evra®)	99.7%, 92.0%
Depo-Provera®	99.7%, 97.0%
Progestin-only pill (Micronor®)	90-99%
Mirena® IUD	99.9%
Copper IUD	99.3%
Surgical	
Tubal ligation	99.65%
Vasectomy	99.9%
Emergency Postcoital Contraception (EPC)	
Yuzpe method	98% (within 24 hours)
“Plan B” levonorgestrel only	98% (within 24 hours)
Postcoital IUD	99.9%

Effectiveness: percentage of women reporting no pregnancy after 1 year of use.

Hormonal Methods

Combined Oral Contraceptive Pills (OCP)

- most contain low dose ethinyl estradiol (20-35 µg) plus progestin (norethindrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
- failure rate (0.3% to 8%) depending on compliance
- monophasic or triphasic formulations (varying amount of progestin throughout cycle)

Transdermal (Ortho Evra®)

- continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
- applied to lower abdomen, back, upper arm, buttocks, NOT breast
- worn for 3 consecutive weeks (changed every week) with 1 week off to allow menstruation
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in women >90 kg body weight
- may not be covered by drug plans

Contraceptive Ring (Nuvaring®)

- thin flexible plastic ring; releases etonogestrel 120 µg/d and estradiol 15 µg/d
- works for 3 weeks then removed for 1 week to allow menstruation
- as effective as OCP in preventing pregnancy (98%)
- avoids first pass effect
- side effects: vaginal infection/irritation, vaginal discharge
- may have better cycle control, i.e. decreased breakthrough bleeding

Starting Hormonal Contraceptives

- thorough history and physical examination including blood pressure and breast exam
- follow-up visit 6 weeks after hormonal contraceptives prescribed
- pelvic exam can be delayed until a subsequent visit

Counselling the Adolescent about Contraception

More than 90% of adolescent pregnancies are unintended and approximately 50% of all pregnancies occur within the first 6 months of initiating sexual activity. In addition, 85% of sexually active women become pregnant within 1 year if no contraception is used and even some of the least effective contraceptive methods markedly decrease the risk of pregnancy.

Rimsza, ME. Counselling the Adolescent about Contraception. *Pediatr Rev* 2003; 24:162.

Risk of Thromboembolism in Women Taking Ethinylestradiol/Drospirenone and Other Oral Contraceptives.

Obstet Gynecol 2007; 110(3):587-93.

Purpose: To compare the association between thromboembolism and the use of ethinylestradiol/drospirenone (ie. Yasmin) or other oral contraceptives.

Study: Cohort study used a health insurer database and followed patients for an average of 7.6 months.

Patients: 22,429 women who had initiated ethinylestradiol/drospirenone were matched to 44,858 who had initiated other oral contraceptives between the age of 10 and 59 years.

Main Outcome: Thromboembolic events.

Results: The incidence rate of thromboembolism was similar between women initiating ethinylestradiol/drospirenone (1.3 per 1000 woman-years) compared to initiating other OCPs (1.4 per 1000 woman-years) (RR 0.9; 95% CI 0.5 – 1.6). Specific events, including deep vein thrombosis and pulmonary embolism also occurred with similar frequencies.

Summary: The risk of thromboembolism is similar in ethinylestradiol/drospirenone compared to other oral contraceptives.

Suppression of Ovarian Activity with a Drospirenone-Containing Oral Contraceptive in a 24/4 Regimen

Contraception 2008; 78:16-25

Study: Double-blind randomized.

Patients: Women aged 18-35 years post-ovulation or had a follicular diameter > 15 mm before day 23 during a pre-treatment cycle.

Intervention: Drospirenone 3mg plus ethinylestradiol 20 mcg administered in 24/4 regimen vs. 21/7 regimen.

Outcome: Suppression of ovarian activity (Hoogland score).

Results: Women on a 24/4 regimen had greater and more consistent ovarian suppression than the 21/7 group. 87.8% in the 24/4 group had no ovarian activity vs. 56% in the 21/7 group.

Irregular breakthrough bleeding often occurs in the first few months after starting OCP. Usually resolves after three cycles.

Table 5. Combined Estrogen and Progestin Contraceptive Methods

Mechanism of Action	Advantages	Side Effects	Contraindications
<ul style="list-style-type: none"> Ovulatory suppression through inhibition of LH and FSH Decidualization of endometrium Thickening of cervical mucus resulting in decreased sperm penetration 	<ul style="list-style-type: none"> Highly effective, reversible Cycle regulation Decreased dysmenorrhea and menorrhagia (less anemia) Decreased benign breast disease and ovarian cyst development Decreased risk of ovarian and endometrial cancer Increased cervical mucus which may lower risk of STIs Decreased PMS symptoms Improved acne Osteoporosis protection (possibly) 	<p>Estrogen-related</p> <ul style="list-style-type: none"> Nausea Breast changes (tenderness, enlargement) Fluid retention/bloating/edema Weight gain (rare) Migraine, headaches Thromboembolic events Liver adenoma (rare) Breakthrough bleeding (low estradiol levels) <p>Progestin-related</p> <ul style="list-style-type: none"> Amenorrhea/breakthrough bleeding Headaches Breast tenderness Increased appetite Decreased libido Mood changes Hypertension Acne/oily skin* Hirsutism* <p>* Androgenic side effects may be minimized by prescribing formulation containing desogestrel, norgestimate, drospirenone or cyproterone acetate</p>	<p>Absolute</p> <ul style="list-style-type: none"> Known/suspected pregnancy Undiagnosed abnormal vaginal bleeding Prior thromboembolic events, thromboembolic disorder (Factor V Leiden mutation; protein C, S or antithrombin III deficiency), active thrombophlebitis Cerebrovascular or coronary artery disease Estrogen-dependent tumours (breast, uterus) Impaired liver function associated with acute liver disease Congenital hypertriglyceridemia Smoker age >35 years Migraines with focal neurological symptoms (excluding aura) Uncontrolled hypertension <p>Relative</p> <ul style="list-style-type: none"> Migraines – non-focal with aura <1 hour Diabetes mellitus complicated by vascular disease SLE Controlled hypertension Hyperlipidemia Sickle cell anemia Gallbladder disease <p>Drug Interactions/Risks</p> <ul style="list-style-type: none"> Rifampin, phenobarbital, phenytoin and primidone can decrease efficacy, requiring use of back-up method No evidence of fetal abnormalities if conceived on OCP No evidence that OCP is harmful to nursing infant but may decrease milk production, not recommended until 6 weeks postpartum

Reference: World Health Organization Guidelines for Oral Contraceptive Pill (OCP) Use

Selected Examples of OCPs**Allesse®**

- 17 µg ethinyl estradiol and 0.5 mg lovonorgestrel
- low-dose therefore often a good starting OCP
- also used to help acne and to regulate menstrual cycles
- low-dose pills can often result in breakthrough bleeding; if this persists for longer than 3 months, patient should be switched to an OCP with higher estrogen content

Tri-cyclen®

- 35 µg ethinyl estradiol and 0.180 / 0.215 / 0.250 mg norgestimate
- triphasic oral contraceptive (graduated levels of progesterone)
- low androgenic activity can help with acne
- triphasic OCPs can not be used continuously (unlike monophasic formulations)

Yasmin® and Yaz®

- Yasmin®: 30 µg ethinyl estradiol + 3 mg drospirenone (a new progestin)
- Yaz®: 20 µg ethinyl estradiol + 3 mg drospirenone – 24/4-day pill (4 day pill free interval)
- drospirenone has antimineralocorticoid activity and antiandrogenic effects
- benefits: decreased perception of cyclic weight gain, bloating; fewer PMS symptoms; improved acne
- adverse effects: hyperkalemia (rare, contraindicated in renal and adrenal insufficiency)
- check potassium if patient also on ACE inhibitor, ARB, K-sparing diuretic, heparin

PROGESTIN-ONLY METHOD**Table 6. Progestin Only Contraceptive Methods**

Contraceptive	Mechanism of Action	Side Effects	Contraindications
<ul style="list-style-type: none"> Suitable for postpartum women (does not affect breast milk supply) Women with contraindications to combined OCP (e.g. thromboembolic or myocardial disease) Women intolerant of estrogenic side effects of combined OCPs 	<ul style="list-style-type: none"> Progestin prevents LH surge Thickening of cervical mucus Decrease tubal motility Endometrial decidualization Ovulation suppression – oral progestins (not IM) do not consistently suppress compared to combined OCPs 	<ul style="list-style-type: none"> Irregular menstrual bleeding Weight gain Headache Breast tenderness Mood changes Functional ovarian cysts Acne/oily skin Hirsutism 	<p>Absolute</p> <ul style="list-style-type: none"> None

**Missed Combined OCPs****Miss 1 pill**

- Take 1 pill as soon as patient remembers, and the next pill at the usual time; OR 2 pills at the next dose.

Miss 2 pills in a row during first 2 weeks of the cycle

- Take 2 pills the day patient remembers, and 2 pills the next day.
- Then 1 pill per day until pack is finished.
- Back-up method of birth control required during next 7 days.

Miss 2 pills in a row during third week of the cycle OR miss 3 in a row at any time

- Throw out pack and start a new pack immediately.
- Back-up method of birth control required during next 7 days.

**Missed Progestin-Only Pills**

Use back-up contraceptive method for at least 48 hours. Continue to take remainder of pills as prescribed.

Canadian Consensus Guideline on Continuous and Extended Hormonal Contraception (2007)

Definitions

*Extended use: The use of combined hormonal contraceptives with planned hormone-free intervals.

*Continuous Use: Uninterrupted use of combined hormonal contraceptive without hormone-free intervals.

What can be used?

Oral, transdermal and vaginally administered combined hormonal contraceptives, including those originally designed for cyclic use, can be administered in a variety of Continuous and Extended (C/E) regimens.

Efficacy and Adherence

Continuous combined hormonal contraceptive regimens are as effective as cyclic regimens in preventing pregnancy. Use of C/E combined hormonal contraceptive may be more "forgiving" about missed combined hormonal contraceptives because of the absence of a hormone-free interval.

Side Effects

The side effect profile of C/E combined hormonal contraceptive regimens is not worse than with cyclic regimens, and may be improved.

Medical/Non-contraceptive Usage

For women in the perimenopausal transition who may be ovulating, C/E combined hormonal contraceptive is preferred to hormonal replacement therapy for controlling problematic bleeding and vasomotor symptoms.

Journal of Obstetrics and Gynaecology Canada (2007) Vol 29, Suppl 2.

Types of IUDs

Copper containing: Nova-T®, Flexi-T®
Progesterone containing: Mirena®

Can be inserted for 5 years and fertility is restored with removal.

Consequences of Long-term Use of Depo-Provera®

Wooltorton E. CMAJ 2005; 172(6):746
Extended use (up to five years) of medroxyprogesterone acetate has been found to decrease spine and hip bone mineral density (BMD) by 4% to 6.9%. Two years after discontinuation, only partial recovery of BMD has been noted.

New SOGC Recommendations for Depo-Provera® Users

SOGC News Release. New recommendations from national ob/gyn society address Depo-Provera®, bone loss. May 2006. http://www.sogc.org/media/pdf/advisories/dmpa-may2006_e.pdf

- Inform patients of potential risks and benefits at intervals throughout course of treatment
- Recommend ways to improve bone health such as calcium, vitamin D, weight-bearing exercise, smoking cessation, decreased alcohol and reduced caffeine
- There is no evidence to suggest routine BMD testing

Selected Examples of Progestin-Only Methods

Progestin-Only Pill ("minipill")

- Micronor® 0.35 mg norethindrone
- taken daily at same time of day to ensure reliable effect; no pill free interval
- higher failure rate (1.1-13% with typical use, 0.51% with perfect use) than other hormonal methods
- ovulation inhibited in 60% of women; most have regular cycles (but may cause oligo/amenorrhea)
- highly effective if also post-partum breastfeeding

Depo-Provera®

- injectable depot medroxyprogesterone acetate
- dose 150 mg IM q12-14wks (convenient dosing)
- initiate within 5 days of beginning of normal menses, immediately postpartum in breastfeeding and non-breastfeeding women
- irregular spotting progresses to complete amenorrhea in 70% of women (after 1-2 years of use)
- highly effective 99%; failure rate 0.3%
- side effect: decreased bone density (may be reversible)
- disadvantage: restoration of fertility may take up to 1-2 years

Intrauterine Device (IUD)

Table 7. IUD Contraceptive Methods

Mechanism of Action	Side Effects	Contraindications
<ul style="list-style-type: none"> • Copper-containing IUD (Nova-T®): mild foreign body reaction in endometrium toxic to sperm and alters sperm motility • Progesterone-releasing IUD (Mirena®): decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation • Highly effective (95-99%); failure rate 0-1.2% • Contraceptive effects last 5 years • Reversible, private, convenient • May be used in women with contraindications to OCPs or wanting long-term contraception 	<ul style="list-style-type: none"> • Copper IUD: increased blood loss and duration of menses, dysmenorrhea • Progesterone IUD: bloating, headache • Breakthrough bleeding • Expulsion (5% in the first year, greatest in first month and in nulliparous women) • Uterine wall perforation (1/1000) on insertion • If pregnancy occurs with an IUD, increased risk of ectopic • Increased risk of PID (within first 10 days of insertion only) 	<p>Absolute</p> <ul style="list-style-type: none"> • Known or suspected pregnancy • Undiagnosed genital tract bleeding • Acute or chronic PID • Lifestyle risk for STIs* • Known allergy to copper (copper IUD only) • Wilson's disease (copper IUD only) <p>Relative</p> <ul style="list-style-type: none"> • Valvular heart disease • Past history of PID or ectopic pregnancy • Presence of prosthesis • Abnormalities of uterine cavity, intracavitary fibroids • Severe dysmenorrhea or menorrhagia (copper IUD only) • Cervical stenosis • Immunosuppressed individuals (e.g. HIV)

*Cervical swabs for gonorrhea and chlamydia should be done prior to IUD insertion

Emergency Postcoital Contraception (EPC)

Table 8. Emergency Contraceptive Methods

	Mechanism of Action	Side Effects	Contraindications
HORMONAL Yuzpe Method <ul style="list-style-type: none"> Used within 72 hours of unprotected intercourse; limited evidence of benefit up to 5 days Ovral® 2 tablets then repeat in 12 hours (ethinyl estradiol 100 µg/levonorgestrel 500 µg) Can substitute with any OCP as long as same dose of estrogen used 2% overall risk of pregnancy Efficacy decreased with time (e.g. less effective at 72 hours than 24 hours) "Plan B" <ul style="list-style-type: none"> Consists of levonorgestrel 750 µg q12h for 2 doses (can also take 2 doses together); taken within 72 hours of intercourse Greater efficacy (75-95% if used within 24 h) and better side effect profile than Yuzpe method but efficacy decreases with time No estrogen thus very few contraindications/side effects (less nausea) 	<ul style="list-style-type: none"> Unknown; suggestions include: <ul style="list-style-type: none"> Suppresses ovulation or causes deficient luteal phase Alters endometrium to prevent implantation Affects sperm/ova transport 	<ul style="list-style-type: none"> Nausea (due to estrogen; treat with Gravol®) Irregular spotting 	<ul style="list-style-type: none"> Pre-existing pregnancy (although not teratogenic) Caution in women with contraindications to OCP (although NO absolute contraindications)
NON-HORMONAL Postcoital IUD (Copper) <ul style="list-style-type: none"> Insert up to 7 days postcoitus Prevents implantation 1% failure rate Can use for short duration in higher risk individuals Mirena® IUD cannot be used as EPC 	<ul style="list-style-type: none"> See Table 7 	<ul style="list-style-type: none"> See Table 7 	<ul style="list-style-type: none"> See Table 7

Follow-up

- 3-4 weeks post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counseling

Any OCP can be used as EPC; 100 µg ethinyl estradiol PO q12h x 2 doses.

Infertility

Epidemiology

- 10-15% of couples
- must investigate both members of couple

Female Factors

Etiology

- ovulatory dysfunction (15-20%)**
 - hypothalamic (hypothalamic amenorrhea)
 - pituitary (prolactinoma, hypopituitarism)
 - ovarian
 - PCOS
 - premature ovarian failure
 - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
 - systemic diseases (thyroid, Cushing's syndrome, renal/hepatic failure)
 - congenital (Turner's syndrome, gonadal dysgenesis or gonadotropin deficiency)
 - stress, poor nutrition, excessive exercise (even with presence of menstruation)
- outflow tract abnormality**
 - tubal factors (20-30%)
 - PID
 - adhesions (previous surgery, peritonitis, endometriosis)
 - ligation/occlusion (e.g. previous ectopic pregnancy)
 - uterine factors (<5%)
 - congenital anomalies (e.g. prenatal DES exposure), bicornuate uterus, uterine septum
 - intrauterine adhesions (e.g. Asherman's syndrome)
 - infection (endometritis, pelvic TB)
 - fibroids/polyps (particularly intrauterine)
 - endometrial ablation
 - cervical factors (5%)
 - hostile or acidic cervical mucus
 - anti-sperm antibodies
 - structural defects (cone biopsies, laser or cryotherapy)

Infertility: inability to conceive or carry to term a pregnancy after one year of regular, unprotected intercourse.

Primary infertility: infertility in the context of no prior pregnancies.

Secondary infertility: infertility in the context of a prior conception.

Generally, 75% of couples achieve pregnancy within 6 months, 85% within 1 year, 90% within 2 years

Requirements for Conception

1. Ovary
2. Tube
3. Cervix
4. Endometrium
5. Sperm

**When should investigations begin?**

- <35 years: after 1 year of regular unprotected intercourse
- 35-40 years: after >6 months
- >40 years: immediately
- Earlier if:
 - History of PID
 - History of infertility in previous relationship
 - Prior pelvic surgery
 - Chemotherapy/radiation in either partner
 - Recurrent pregnancy loss
 - Moderate-severe endometriosis

**Controversial and Evolving Ethical Issues**

- Infertility demands non-judgmental discussion
- Ethical issues surrounding therapeutic donor insemination in same sex couples, surrogacy, donor egg and other advanced reproductive technologies are still evolving and remain controversial
- If certain options lie outside physician's moral boundaries, infertile couple should be referred to another physician

**Summary of Current Legislation in Canada****Bill C-13 Assisted Human Reproduction Act 2004:****WHAT IS NOT ALLOWED**

- Cloning people
- Cloning stem cells
- Growing human embryos for research
- Sex selection
- Making changes to human DNA that would pass from one generation to the rest
- Creating people who have animal DNA
- Buying or selling embryos, sperm, eggs or other human reproductive material

WHAT IS ALLOWED

- Surrogate mothers
- Donating sperm, eggs and other reproductive material
- Using embryos, sperm, eggs, etc., to assist conception
- Using human embryos and stem cells in research

**Normal Semen Analysis (WHO criteria)**

- Must be obtained after 48-72 hours of abstinence
 1. Volume 2-5 cc
 2. Count >20 million/cc
 3. Motility >50% forward progression
 4. Morphology >30% normal
 5. Absence of pyospermia, hyperviscosity, agglutination

NB: does not assess sperm function

- endometriosis (15-30%)
- multiple factors (30%)
- unknown factors (10-15%)

Investigations

- **ovulatory**
 - day 3: FSH, LH, TSH, PRL ± DHEA, free testosterone (if hirsute)
 - day 21-23: serum progesterone to confirm ovulation
 - initiate basal body temperature monitoring (biphasic pattern)
 - postcoital test: evaluate mucus for clarity, pH, spinnbarkeit (rarely done)
- **tubal factors**
 - HSG (can be therapeutic – opens fallopian tube)
 - SHG
 - laparoscopy with dye insufflation
- **peritoneal/uterine factors**
 - HSG/SHG, hysteroscopy
- **other**
 - karyotype

Treatment

- **education:** timing of intercourse in relation to ovulation (from 2 days prior to 2 days following presumed ovulation), every other day
- **medical**
 - ovulation induction
 - ♦ clomiphene citrate (Clomid®): estrogen antagonist that causes a perceived decreased estrogen state, resulting in increased pituitary gonadotropins; causes increased FSH and LH, leading to ovulation induction (better if anovulatory)
 - ♦ human menopausal gonadotropin [HMG (Pergonal®)], urofollitropin [FSH (Metrodin®)]
 - FSH and LH extracted from urine of postmenopausal women
 - ♦ followed by beta-hCG for stimulation of ovum release
 - may add
 - ♦ bromocriptine (dopamine agonist) if elevated prolactin
 - ♦ dexamethasone for hyperandrogenism (adult onset congenital adrenal hyperplasia), metformin (PCOS)
 - ♦ luteal phase progesterone supplementation for luteal phase defect
 - ♦ ASA (81 mg PO OD) daily for women with a history of recurrent spontaneous abortions
- **surgical/procedural**
 - tuboplasty
 - lysis of adhesions
 - artificial insemination
 - sperm washing
 - IVF (in vitro fertilization)
 - intrafallopian transfers
 - GIFT (gamete intrafallopian transfer): immediate transfer with sperm after oocyte retrieval
 - ZIFT (zygote intrafallopian transfer): transfer after 24 hour culture of oocyte and sperm
 - TET (tubal embryo transfer): transfer after >24 hour culture
 - ICSI (intracytoplasmic sperm injection)
 - IUI (intrauterine insemination)
 - ± oocyte or sperm donors
 - IVM (in vitro maturation)

Male Factors

- see Urology, U34

Etiology

- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)

Investigations

- semen analysis and culture
- post-coital (Huhner) test: rarely done

Polycystic Ovarian Syndrome (PCOS)

- also called chronic ovarian androgenism

Etiology

Figure 12. Pathophysiology of Polycystic Ovarian Syndrome

Diagnosis

- 2 of 3 to make diagnosis
 1. oligomenorrhea/irregular menses for 6 months
 2. clinical or lab evidence of hyperandrogenism
 3. polycystic ovaries on U/S

Clinical Features

- average age 15-35 years at presentation
- abnormal/irregular uterine bleeding, hirsutism, infertility, obesity, virilization
- insulin resistance occurs in both lean and obese patients
- acanthosis nigricans: browning of skin folds in intertriginous zones (indicative of insulin resistance)
- family history of diabetes

Investigations

- goal of investigations is to identify hyperandrogenism or chronic anovulation and rule out specific pituitary or adrenal disease as the cause
- labs
 - prolactin, 17-hydroxyprogesterone, free testosterone, DHEA-S, TSH, free T₄, androstenedione, sex hormone binding globulin (SHBG)
 - LH:FSH >2:1; LH is chronically high with FSH midrange or low (low sensitivity and specificity)
 - increased DHEAS, androstenedione and free testosterone (most sensitive), decreased SHBG
- transvaginal ultrasound: polycystic-appearing ovaries ("string of pearls")
- tests for insulin resistance or glucose tolerance
 - fasting glucose:insulin ratio <4.5 is consistent with insulin resistance (U.S. units)
 - 75g OGTT (particularly if obese)
- laparoscopy
 - not required for diagnosis
 - most common to see white, smooth, sclerotic ovary with a thick capsule; multiple follicular cysts in various stages of atresia; hyperplastic theca and stroma
- rule out other causes of abnormal bleeding

Treatment

- **cycle control**
 - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
 - OCP monthly or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
 - oral hypoglycemic (e.g. metformin)
 - tranexamic acid (Cyklokapron®) for menorrhagia only
- **infertility**
 - medical induction of ovulation: clomiphene citrate, human menopausal gonadotropins [hMG (Pergonal®)], LHRH, recombinant FSH, and metformin
 - ♦ metformin may be used alone or in conjunction with clomiphene citrate for ovulation induction
 - ovarian drilling (perforate the stroma), wedge resection of the ovary
 - bromocriptine (if hyperprolactinemia)
- **hirsutism**
 - any OCP can be used
 - ♦ Diane 35® (cyproterone acetate): antiandrogenic
 - ♦ Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
 - mechanical removal of hair
 - finasteride (5-alpha reductase inhibitor)
 - flutamide (androgen reuptake inhibitor)

Clinical Signs of Endocrine Imbalance

- Menstrual disorder/amenorrhea (80%)
- Infertility (74%)
- Hirsutism (69%)
- Obesity (49%)
- Impaired glucose tolerance (35%)
- Diabetes Mellitus (10%)

Polycystic Ovarian Syndrome – HAIR-AN

Hirsutism, HyperAndrogenism, Infertility, Insulin Resistance, Acanthosis Nigricans

PCOS may be Confused with:

- Late onset congenital adrenal hyperplasia (21-hydroxylase deficiency)
- Cushing's syndrome
- Ovarian and adrenal neoplasms
- Hyperprolactinemia
- Hypothyroidism

Diagnostic Criteria for Polycystic Ovary Syndrome: Pitfalls and Controversies

Lujan ME et al. JGCM 2008.

At present, there is no clear-cut definition of biochemical hyperandrogenemia, particularly since there is dependence on poor laboratory standards for measuring androgens in women. Clinical signs of hyperandrogenism are ill-defined in women with PCOS, and diagnosis of both hirsutism and polycystic ovarian morphology remains subjective. There is also inappropriate tendency to assign ovulatory status solely on basis of menstrual cycle history or poorly timed endocrine measurements. Therefore it is important as clinicians to recognize the multi-factorial and complex nature of PCOS and place this in context of our present diagnostic limitations.

Long Term Health Consequences

- Hyperlipidemia
- Adult-onset diabetes mellitus
- Endometrial hyperplasia
- Infertility
- Obesity
- Sleep apnea

Use of Metformin in Polycystic Ovary Syndrome. A Meta-Analysis.

Obstet Gynecol 2008; 111(4):959-68.

Study: This meta-analysis of 17 RCTs assessed the efficacy of metformin or metformin in combination with clomiphene citrate in women with polycystic ovary syndrome (PCOS) who were seeking pregnancy.

Main Outcomes: Ovulation, pregnancy, and live birth.

Patients: 1,639 patients with PCOS were followed up for up to 12 months.

Results: Compared to placebo, metformin increased the odds of ovulation (OR 2.94, 95% CI 1.43 – 6.02). However, when used alone, metformin did not significantly increase the odds of achieving pregnancy (OR 1.56, 95% CI 0.74 – 3.33). When compared to clomiphene alone, the combination of metformin and clomiphene increased the likelihood of ovulation (OR 4.39, 95% CI 1.94 – 9.96) and pregnancy (OR 2.67, 95% CI 1.45 – 4.94). The effect of combination therapy was most prominent in clomiphene-resistant and obese women with PCOS. Furthermore, the combination therapy had a higher likelihood of having a live birth compared to clomiphene alone, but this did not reach significance (OR 1.74, 95% CI 0.79 – 3.86).

Conclusions: Metformin increases the likelihood of ovulation. When used together with clomiphene, metformin increases the likelihood of both ovulation and pregnancy, especially in clomiphene-resistant and obese women.

Gynecological Infections

Physiologic Discharge

- clear, white, flocculent odourless discharge; pH 3.8-4.2
- smear contains epithelial cells, *Lactobacilli*
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

Vulvovaginitis

Vulvovaginitis

Vulvar and vaginal inflammation.

Most common gynecological problem in prepubertal girls is non-specific vulvovaginitis.

There is no high quality evidence showing a link between vulvovaginal candidiasis and hygienic habits or wearing tight or synthetic clothing.

Prepubertal and Adolescent Gynecological Infections: Legal Aspects of Confidentiality

- Clinicians who treat adolescents must be aware of federal, state and provincial laws related to adolescent consent and confidentiality.
- They must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice.

PREPUBERTAL VULVOVAGINITIS

• clinical features

- irritation, pruritus
- discharge
- vulvar erythema
- vaginal bleeding (specifically due to Group A *Streptococci* and *Shigella*)

• differential diagnosis

- non-specific vulvovaginitis (25-75%)
- infections (respiratory, enteric, systemic, sexually acquired)
- foreign body (toilet paper most common)
- candida (if using diapers)
- pinworms
- polyps, tumour (ovarian malignancy)
- vulvar skin disease (lichen sclerosis, condyloma acuminata)
- trauma (accidental straddle injury, sexual abuse)
- psychosomatic vaginal complaints (specific to vaginal discharge)
- endocrine abnormalities (specific to vaginal bleeding)
- blood dyscrasia (specific to vaginal bleeding)

• etiology

- infectious:
 - ♦ poor hygiene, proximity of vagina to anus
 - ♦ recent infection (respiratory, enteric, systemic)
 - ♦ STI: investigate sexual abuse
- nonspecific:
 - ♦ lack of protective hair and labial fat pads
 - ♦ lack of estrogenization
 - ♦ susceptible to chemicals, soaps (bubble baths), medications and clothing
 - ♦ enuresis

• investigations

- vaginal swab for culture (specifically state that it is a pre-pubertal specimen)

• treatment

- enhanced hygiene and local measures (handwashing, white cotton underwear, no nylon tights, no tight fitting clothes, no sleeper pajamas, sitz baths, avoid bubble baths, use mild detergent, eliminate fabric softener, avoid prolonged exposure to wet bathing suits, urination with legs spread apart)
- A&D® dermatological ointment to protect vulvar skin
- infectious: treat with antibiotics for organism identified

Table 9. Other Common Causes of Vulvovaginitis in Prepubertal Girls

	Pinworms	Lichen Sclerosis	Foreign Body
Diagnosis	Cellophane Tape test	Area of white patches and thinning of skin	
Treatment	Empirical treatment with mebendazole	Topical steroid creams	Irrigation of vagina with saline, may require local anesthesia or an exam under anesthesia

POSTMENOPAUSAL VAGINITIS/ATROPHIC VAGINITIS

- **clinical features**
 - dyspareunia
 - post-coital spotting
 - mild pruritus
- **investigations**
 - atrophy is usually a visual diagnosis: thinning of tissues, erythema, petechiae, bleeding points, dryness on speculum exam
 - rule out malignancy: especially endometrial cancer
- **treatment**
 - local estrogen replacement (ideal): Premarin® cream, VagiFem® tablets, or Estrin®
 - oral or transdermal hormone replacement therapy (if treatment for systemic symptoms is desired)
 - good hygiene

INFECTIOUS VULVOVAGINITIS**Table 10. Infectious Vulvovaginitis**

	Candidiasis (Moniliasis)	Bacterial Vaginosis (BV)	Trichomoniasis
Organisms	<i>Candida albicans</i> (90%) <i>Candida glabrata</i> (<5%) <i>Candida tropicalis</i> (<5%)	<i>Gardnerella vaginalis</i> <i>Mycoplasma hominis</i> Anaerobes: <i>Prevotella</i> , <i>Mobiluncus</i> , <i>Bacteroides</i>	<i>Trichomonas vaginalis</i> (flagellated protozoan)
Pathophysiology or Transmission	Predisposing factors include: <ul style="list-style-type: none"> • Immunosuppressed host (diabetes, AIDS, etc.) • Recent antibiotic use • Includes estrogen levels (e.g. pregnancy, OCP) 	Replacement of vaginal <i>Lactobacillus</i> with organisms above	Sexually transmitted
Discharge	Whitish, "cottage cheese," minimal	Grey, thin, diffuse	Yellow-green, malodorous, diffuse
Other	• 20% asymptomatic	• 50-75% asymptomatic	• 25% asymptomatic
Signs/Symptoms	• Intense pruritus • Swollen, inflamed genitals • Vulvar burning, dysuria, dyspareunia	• Fishy odour, esp. after coitus • Absence of vulva/vaginal irritation	• Petechiae on vagina and cervix • Occasionally irritated tender vulva • Dysuria, frequency
pH	≤4.5	>4.5	≤4.5
Saline Wetmount	KOH wetmount reveals hyphae and spores	1) >20% clue cells = squamous epithelial cells dotted with coccobacilli (<i>Gardnerella</i>) 2) Paucity of WBC 3) Paucity of <i>Lactobacilli</i> 4) Positive whiff test = fishy odour with addition of KOH to slide (due to formation of amines)	1) Motile flagellated organisms 2) Many WBC 3) Inflammatory cells (PMNs)
Treatment	<ul style="list-style-type: none"> • Clotrimazole, butoconazole, miconazole, terconazole suppositories and/or creams for 1, 3 or 7-day treatments • Treatment in pregnancy is usually topical treatment • fluconazole 150 mg PO in single dose 	<ul style="list-style-type: none"> • No treatment if non-pregnant and asymptomatic, unless scheduled for pelvic surgery or procedure Oral <ul style="list-style-type: none"> • Metronidazole 500 mg PO bid x 7 days or metronidazole gel 0.75% x 5 day OD • Clindamycin 2% 5 g intravaginally at bedtime for 7 days Topical <ul style="list-style-type: none"> • May use metronidazole in pregnancy 	<ul style="list-style-type: none"> • Treat even if asymptomatic! • Metronidazole 2 g PO single dose or 500 mg bid x 7 days (alternative) • Symptomatic pregnant women should be treated with 2 g metronidazole once
Other	<ul style="list-style-type: none"> • For repeat infections prophylaxis, treatment includes boric acid, vaginal suppositories, luteal phase fluconazole • Routine treatment of partner(s) not recommended (not sexually transmitted) 	<ul style="list-style-type: none"> • Associated with recurrent and preterm labour, preterm birth and postpartum endometritis in pregnancy • Need to warn patients on metronidazole not to consume alcohol (disulfiram-like action) • Routine treatment of partner(s) not recommended (not sexually transmitted) 	<ul style="list-style-type: none"> • Warnings accompanying metronidazole use • Treat partner(s)

Sexually Transmitted Infections (STIs)

- see Family Medicine, FM43

STI Testing

1. Vaginal swab
 - Tests for bacterial vaginosis, trichomoniasis, candida
2. Cervical swab
 - Test for gonorrhea and chlamydia

Risk Factors for STIs

- History of previous STI
- Contact with infected person
- Sexually active individual age <25 years
- Multiple partners
- New partner in last 3 months
- Not using barrier protection
- Street involvement (homelessness, drug use)

Public Health Agency of Canada: National Notifiable STIs

- HIV
- Gonorrhea
- Chlamydia
- Syphilis
- Hepatitis B, C, D

Figure 13. Speculum Exam

TRICHOMONIASIS

- see *Infectious Vulvovaginitis*, GY25

CHLAMYDIA

Etiology

- *Chlamydia trachomatis*

Epidemiology

- most common bacterial STI in Canada
- often associated with *N. gonorrhoeae*

Clinical Features

- asymptomatic (80% of women)
- muco-purulent endocervical discharge
- urethral syndrome: dysuria, frequency, pyuria, no bacteria
- pelvic pain
- post-coital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
- symptomatic sexual partner

Investigations

- cervical culture or nucleic acid amplification test
- obligate intracellular parasite – tissue culture is the definitive standard
- urine and vaginal test now available, which are equally or more effective than cervical culture

Treatment

- doxycycline 100 mg PO bid for 7d or azithromycin 1 g PO in a single dose (may use in pregnancy)
- also treat gonorrhea because of high rate of co-infection
- treat partners
- reportable disease
- test of cure for chlamydia required in pregnancy (cure rates lower in pregnant patients) → re-test 3-4 weeks after initiation of therapy

Screening

- high risk groups
- during pregnancy

Complications

- acute salpingitis, PID
- Fitz-Hugh-Curtis syndrome (liver capsule infection)
- arthritis, conjunctivitis, urethritis (reactive arthritis – male predominance, HLA-B27)
- infertility – tubal obstruction from low grade salpingitis
- ectopic pregnancy
- chronic pelvic pain
- perinatal infection – conjunctivitis, pneumonia

GONORRHEA**Etiology**

- *Neisseria gonorrhoeae*
- symptoms and risk factors same as with chlamydia

Investigations

- Gram stain shows Gram-negative intracellular diplococci
- cervical, rectal and throat culture

Treatment

- single dose of ceftriaxone 125 mg IM, or cefixime 400 mg PO, or ciprofloxacin 500 mg PO
- if pregnant – cephalosporin regimen or 2 g spectinomycin IM (avoid quinolones)
- also treat chlamydia, because of high rate of co-infection
- treat partners
- reportable disease
- screening as with chlamydia

HUMAN PAPILLOMAVIRUS (HPV)**Etiology**

- most common viral STI in Canada
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma

Clinical Features

- latent infection
 - no visible lesions, asymptomatic
 - only detected by DNA hybridization tests
- subclinical infection
 - visible lesion found during colposcopy or on Pap test
- clinical infection
 - visible wart-like lesion without magnification
 - hyperkeratotic, verrucous or flat, macular lesions
 - vulvar edema

Investigations

- cytology (see *Cervical Screening (Pap Test)*, GY43)
 - koilocytosis – nuclear enlargement and atypia with perinuclear halo
- biopsy of lesions at colposcopy
- detection of HPV DNA subtype using nucleic acid probes not routinely done but can be done in presence of abnormal Pap test to guide treatment

Treatment

- patient administered:
 - podofilox 0.5% solution or gel bid x 3 days in a row (4 days off) then repeat x 4 weeks
 - imiquimod (Aldara®) 5% cream 3x/wk qhs x 16wks
- provider administered:
 - cryotherapy with liquid nitrogen: repeat q1-2wks
 - podophyllin resin in tincture of benzoin: weekly
 - trichloroacetic acid (TCA) or bichloroacetic acid weekly (80-90%); safe in pregnancy
 - surgical removal/laser
 - intralesional interferon

Prevention

- HPV types 6, 11, 16, 18 – preventable with Gardasil® (quadrivalent HPV recombinant vaccine)
- cannot be prevented by using condoms

Test of cure for *C. trachomatis* and *N. gonorrhoeae* is not routinely indicated. Repeat testing if symptomatic, if compliance with treatment is uncertain, or if pregnant.

**Genital Warts During Pregnancy**

- Condyloma tend to get larger in pregnancy and should be treated early (consider excision).
- C-section only if obstruction of birth canal or risk of extensive bleeding.
- Do not use imiquimod, podophyllin or podofilox.

**Human Rights in Health Equity: Cervical Cancer and HPV Vaccines**

Erdman, JN. *American Journal of Law & Medicine*. 2009

- While cervical cancer rates have drastically fallen in developed countries due to effective prevention and treatment, socially disadvantaged women within these countries remain disproportionately more likely to develop and die of cervical cancer.
- In most developing countries, in contrast, cervical cancer rates have risen or remained unchanged.
- Must recognize that cervical cancer disparities between race groups, urban and rural residence, and high and low wealth status are attributed to disparate screening and vaccination coverage.
- Programs are implemented without sufficient attention to conditions that render screening less effective or inaccessible to disadvantaged social groups including: lack of information, undervaluing of preventive care, opportunistic delivery in limited health care settings, sexual health stigma and related privacy concerns.

HERPES SIMPLEX VIRUS OF VULVA (HSV)

Etiology

- 90% are HSV-2, 10% are HSV-1

Clinical Features

- may be asymptomatic
- initial symptoms: present 2-21 days following contact
- prodromal symptoms: tingling, burning, pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 days after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: less severe, less frequent and shorter in duration (especially with HSV-1)

Investigations

- viral culture preferred in patients with ulcer present – decreased sensitivity as lesions heal
- cytologic smear
 - multinucleated giant cells, acidophilic intranuclear inclusion bodies
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not available routinely in Canada)
- HSV DNA PCR

Treatment

- first episode
 - acyclovir 400 mg PO tid x 7-10d, or famciclovir 250 mg PO tid x 7-10d, or valacyclovir 1 g PO bid x 7-10d
- recurrent episode
 - acyclovir 400 mg PO tid x 3-5d, or famciclovir 125 mg PO bid x 3-5d, or valacyclovir 500 mg PO bid x 3d
- daily suppressive therapy
 - consider if 6-8 recurrences per year
 - acyclovir 400 mg PO bid, or famciclovir 250 mg bid, or valacyclovir 0.5-1 g PO OD
- severe disease
 - consider IV therapy acyclovir 5-10 mg/kg IV q8h x 5-7d
- education regarding transmission
- avoid contact from onset of prodrome until lesions have cleared
- use barrier contraception

SYPHILIS

Etiology

- *Treponema pallidum*

Classifications

- progresses in stages
- **primary syphilis**
 - 3-4 weeks after exposure
 - painless chancre on vulva, vagina or cervix
 - painless inguinal lymphadenopathy
 - serological tests usually negative, local infection only
- **secondary syphilis** (can resolve spontaneously)
 - 2-6 months after initial infection
 - nonspecific symptoms: malaise, anorexia, headache, diffuse lymphadenopathy
 - generalized maculopapular rash: palms, soles, trunk, limbs
 - condylomata lata: anogenital, broad-based fleshy grey lesions
 - serological tests usually positive
- **latent syphilis**
 - no clinical manifestations; detected by serology only
- **tertiary syphilis**
 - may involve any organ system
 - neurological: tabes dorsalis, general paresis
 - cardiovascular – aortic aneurysm, dilated aortic root
 - vulvar gumma: nodules that enlarge, ulcerate and become necrotic (rare)
- **congenital syphilis**
 - may cause fetal anomalies, stillbirths or neonatal death

Classically...

HSV I – disease above the belt (oral)

HSV II – disease below the belt (genital)

HSV Infections During Pregnancy

- Antiviral suppression of women with first episode or history of HSV infections from 36 weeks GA on.
- C-section should be performed on women who have active genital lesions at time of delivery.
- Treatment: acyclovir 400 mg PO tid.

Epidemiology of Genital Ulcers

HSV	70-80%
1° syphilis	5%
Chancroid	<1%

Investigations

- aspirate of ulcer serum or node
- darkfield microscopy (most sensitive and specific diagnostic test for syphilis)
 - spirochetes
- non-treponemal screening tests (VDRL, RPR); nonreactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
 - confirmatory tests; remain reactive for life (even after adequate treatment)

Treatment

- treatment of primary, secondary, latent syphilis of <1 year duration
 - benzathine penicillin G 2.4 million units IM single dose
 - treat partners, reportable disease
- treatment of latent syphilis >1 year duration
 - benzathine penicillin G 2.4 million units IM q1wk x 3 weeks
- treatment of neurosyphilis
 - IV aqueous penicillin G 3-4 million units IM q4h for 10-14 days
- screening
 - high risk groups
 - in pregnancy (see Obstetrics, Table 10, OB19)

Complications

- if untreated, 1/3 will experience late complications

HIV

- see Infectious Diseases, ID29

Bartholinitis/Bartholin Gland Abscess

Etiology

- often anaerobic and polymicrobial
- *U. urealyticum*, *N. gonorrhoeae*, *C. trachomatis*, *E. coli*, *P. mirabilis*, *Streptococcus* spp., *S. aureus* (rare)
- blockage of duct

Clinical Features

- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

Treatment

- sitz baths, warm compresses
- antibiotics
- incision and drainage using local anesthesia with placement of Word catheter (10 Fr. latex catheter) for 2-3 weeks
- marsupialization under general anesthetic – more definitive treatment
- rarely treated by removing gland

Pelvic Inflammatory Disease (PID)

- up to 20% of all gynecology-related hospital admissions

Etiology

- causative organisms (in order of frequency)
 - *C. trachomatis*
 - *N. gonorrhoeae*
 - gonorrhea and chlamydia often co-exist
 - endogenous flora: anaerobic, aerobic, or both
 - ♦ *E. coli*, *Staphylococcus*, *Streptococcus*, *Bacteroides*, *Peptostreptococcus*, *H. influenzae*, *G. vaginalis*
 - ♦ cause of recurrent PID
 - ♦ associated with instrumentation
 - *Actinomyces israelii* (Gram-positive, non acid-fast anaerobe)
 - ♦ in 1-4% of PID associated with IUDs
 - others (TB, Gram-negatives, CMV, *U. urealyticum*, etc.)

Risk Factors

- age <30 years
- risk factors as for chlamydia and gonorrhea
- vaginal douching
- IUD (within first 10 days after insertion)
- invasive gynecologic procedures (D&C, endometrial biopsy)

PID

Inflammation of the upper genital tract (above cervix) including endometrium, fallopian tubes, ovaries, pelvic peritoneum, ± contiguous structures.

PID accounts for up to 20% of all gynecology hospital admissions.

**PID Diagnosis**

- **Must** have:
 - Lower abdominal pain
 - Cervical motion tenderness
 - Adnexal tenderness
- **Plus** one or more of:
 - High risk partner
 - Temperature >38°C
 - Mucopurulent cervical discharge
 - Positive culture for *N. gonorrhoeae*, *C. trachomatis*, *E. coli*, or other vaginal flora
 - Cul-de-sac fluid, pelvic abscess or inflammatory mass on U/S or bimanual
 - Leukocytosis
 - Elevated ESR or CRP (not commonly used)

Clinical Presentation

- up to 2/3 asymptomatic: many subtle or mild symptoms
- common
 - fever >38.3°C
 - lower abdominal pain and tenderness
 - abnormal discharge: cervical or vaginal
- uncommon
 - nausea and vomiting
 - dysuria
 - AUB
- chronic disease (often due to chlamydia)
 - constant pelvic pain
 - dyspareunia
 - palpable mass
 - very difficult to treat, may require surgery

Investigations

- bloodwork
 - β -hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine R&M
- speculum exam, bimanual exam
 - vaginal swab for Gram stain, C&S
 - cervical cultures for *N. gonorrhoeae*, *C. trachomatis*
 - endometrial biopsy will give definitive diagnosis (rarely done)
- ultrasound
 - may be normal
 - free fluid in cul-de-sac
 - pelvic or tubo-ovarian abscess
 - hydrosalpinx (dilated fallopian tube)
- laparoscopy (gold standard)
 - for definitive diagnosis: may miss subtle inflammation of tubes or endometritis

Treatment

- must treat with polymicrobial coverage
- **inpatient if:**
 - moderate to severe illness
 - atypical infection
 - adnexal mass, tubo-ovarian or pelvic abscess
 - unable to tolerate oral antibiotics or failed oral therapy
 - immunocompromised
 - pregnant
 - adolescent – first episode
 - surgical emergency cannot be excluded (e.g. ovarian torsion)
 - PID is secondary to instrumentation
 - recommended treatment
 - ♦ cefoxitin 2 g IV q6h (no longer available in U.S.A.) or cefotetan 2 g IV q12h + doxycycline 100 mg IV/PO q12h or
 - ♦ clindamycin 900 mg IV q8h + gentamicin 2 mg/kg IV loading dose then gentamicin 1.5 mg/kg q8h maintenance dose
 - ♦ continue IV antibiotics for 24 hours after symptoms have improved then doxycycline 100 mg PO bid to complete 14 days
 - ♦ percutaneous drainage of abscess under U/S guidance
 - ♦ when no response to treatment, laparoscopic drainage
 - ♦ if failure, treatment is surgical (salpingectomy, TAH/BSO)
- **outpatient if:**
 - typical findings
 - mild to moderate illness
 - oral antibiotics tolerated
 - compliance ensured
 - follow-up within 48-72 hours (to ensure symptoms not worsening)
 - recommended treatment
 - ♦ ofloxacin 400 mg PO bid x 14d or levofloxacin 500 mg PO bid x 14d ± metronidazole 500 mg PO bid x 14d (if suspect abscess)
 - ♦ ceftriaxone 250 mg IM x 1 + doxycycline 100 mg PO bid x 14d or cefoxitin 2 g IM x 1 + probenecid 1 g PO + doxycycline 100 mg PO bid ± metronidazole 500 mg PO bid x 14d
 - ♦ consider removing IUD after a minimum of 24 hours of treatment
 - ♦ reportable disease
 - ♦ treat partners
 - ♦ consider re-testing for *C. trachomatis* and *N. gonorrhoeae* 4-6 weeks after treatment if documented infection

Treat PID with
FOXY DOXY
(cefoxitin + doxycycline)

For patients with contraindications to treatment with cephalosporins or quinolones, recent evidence suggests that a short course of azithromycin at a dose of either 250 mg PO daily for one week or 1 g PO weekly for two weeks combined with metronidazole is effective in achieving a clinical cure for acute PID.

Source: Update to the Canadian Guidelines on Sexually Transmitted Infections. October 2008.

Complications of Untreated PID

- chronic pelvic pain
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
 - 1 episode of PID → 13% infertility
 - 2 episodes of PID → 36% infertility
- bacteremia
- septic arthritis, endocarditis

**PID Complications****I FACE PID**

Infertility
 Fitz-Hugh-Curtis syndrome
 Abscesses
 Chronic pelvic pain
 Ectopic pregnancy
 Peritonitis
 Intestinal obstruction
 Disseminated infection (sepsis, endocarditis, arthritis, meningitis)

Toxic Shock Syndrome

- see Infectious Diseases, ID27

Risk Factors

- tampon use
- diaphragm, cervical cap or sponge use (prolonged use, i.e. >24 hours)
- wound infections
- post-partum infections
- early recognition and treatment of syndrome is imperative as incorrect diagnosis can be fatal

Clinical Presentation

- sudden high fever
- sore throat, headache, diarrhea
- erythroderma
- signs of multisystem organ failure
- refractory hypotension
- exfoliation of palmar and plantar surfaces of the hands and feet 1-2 weeks after onset of illness

Treatment

- remove potential sources of infection (foreign objects and wound debris)
- debride necrotic tissues
- adequate hydration
- penicillinase-resistant antibiotics, e.g. cloxacillin
- steroid use controversial but if started within 72 hours, may reduce severity of symptoms and duration of fever

Toxic Shock Syndrome

Multiple organ system failure due to *S. aureus* exotoxin (rare condition).

Surgical Infections

Post-Operative Infections in Gynecological Surgery

- pelvic cellulitis
 - common post hysterectomy, affects vaginal vault
 - erythema, induration, tenderness, discharge involving vaginal cuff
 - treat if fever and leukocytosis with broad spectrum antibiotics, i.e. clindamycin and gentamicin
 - drain if excessive purulence or large mass
 - can result in intra-abdominal and pelvic abscess
- see General Surgery, *Post-Operative Fever*, GS7

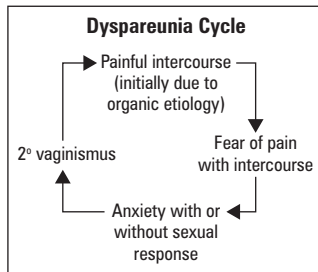

Sexuality and Sexual Dysfunction

SEXUAL RESPONSE

1. desire: energy that allows an individual to initiate or respond to sexual stimulation
2. arousal: physical and emotional stimulation leading to breast and genital vasodilation and clitoral engorgement
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 minutes

SEXUAL DYSFUNCTION**Etiology**

- intrapsychic: patient's life experiences, value system
- relationship/interpersonal issues
- physical/organic

Classification

- lack of desire (60-70% of women)
- lack of arousal
- anorgasmia (5-10%)
 - primary anorgasmia: never before achieved orgasm under any circumstances
 - secondary anorgasmia: was able to achieve orgasms before but now unable
- dyspareunia (3-6%) – painful intercourse, superficial or deep
 - vaginismus (15%)
 - vulvodynia
 - vaginal atrophy
 - vulvar vestibulitis: associated with history of frequent yeast infections
 - PID

Treatment

- lack of desire – assess factors, rule out organic causes, relationship therapy, sensate focus exercises
- anorgasmia – self-exploration/pleasuring, relationship therapy if needed, bridging techniques (different sexual positions, clitoral stimulation during intercourse)
- dyspareunia
 - Kegel and reverse Kegel exercises
 - dilator treatment
 - comfort with self-exam
 - psychotherapy, other behavioural techniques
 - female on top position – allows for control of speed and duration
 - vestibulitis – remove local irritants, change in contraceptive methods, and dietary changes (increased citrate, decreased oxalate), vestibulectomy (rare)
 - vulvodynia – local moisturization, cold compresses, systemic nerve blocking therapy (amitriptyline, neurontin), topical anesthetic, estrogen cream

Kegel Exercises

Regular contraction and relaxation to strengthen pelvic floor muscles.

Reverse Kegel Exercises

1 second contraction then 5 seconds of relaxation.

Menopause

- see Family Medicine, FM41

Definitions

- types of menopause
 - physiological; average age 51 years (follicular atresia)
 - premature ovarian failure; before age 40 (autoimmune disorder, infection, Turner's syndrome)
 - iatrogenic (surgical/radiation/chemotherapy)

Clinical Features

- associated with estrogen deficiency
 - vasomotor instability (tends to dissipate with time)
 - ♦ hot flushes/flushes, night sweats, sleep disturbances, formication, nausea, palpitations
 - urogenital atrophy involving vagina, urethra, bladder
 - ♦ dyspareunia, vaginal itching, vaginal dryness, bleeding, urinary frequency, urgency, incontinence
 - skeletal
 - ♦ osteoporosis, joint and muscle pain, back pain
 - skin and soft tissue
 - ♦ decreased breast size, skin thinning/loss of elasticity
 - psychological
 - ♦ mood disturbance, irritability, fatigue, decreased libido, memory loss

Investigations

- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
- decreased levels of estradiol (later)

Treatment

- goal is for individual symptom management
 - vasomotor instability
 - ♦ HRT (first line), clonidine, SSRI, Effexor®, gabapentin, propranolol
 - vaginal atrophy
 - ♦ local estrogen – cream (Premarin®), vaginal suppository (VagiFem®), ring (Estring®)
 - ♦ lubricants (Replens®)
 - urogenital health
 - ♦ lifestyle changes (weight loss, bladder re-training), local estrogen replacement, surgery

- **Menopause:** occurrence of last spontaneous menstrual period, resulting from loss of ovarian function (loss of oocyte response to gonadotropins).

- **"Being in menopause":** lack of menses for 1 yr.

- **Perimenopause:** period of time surrounding menopause (2-8 yrs preceding + 1 yr after last menses) characterized by fluctuating hormone levels, irregular menstrual cycles, and symptom onset.

- 85% of women experience hot flashes
- 20-30% seek medical attention
- 10% are unable to work

- Osteoporosis is the single most important health hazard associated with menopause.
- Cardiovascular disease is the leading cause of death post-menopause.

- Increased risk of breast cancer (RR 1.3) is associated with HRT use.
- All women taking HRT should have periodic surveillance and counselling regarding its benefits and risks.

- osteoporosis
 - 1000-1500 mg calcium daily, 800-1000 IU vitamin D, weight-bearing exercise, quit smoking
 - bisphosphonates (e.g. alendronate)
 - selective estrogen receptor modifiers (SERMs): raloxifene (Evista®) – mimics estrogen effects on bone, avoids estrogen-like action on breast and uterine cancer; does not help hot flashes
 - HRT: second-line treatment (unless for vasomotor instability as well)
- decreased libido
 - vaginal lubrication, counselling, androgen replacement (testosterone cream)
- cardiovascular disease
 - management of cardiovascular risk factors
- mood and memory
 - antidepressants (first line), HRT (augments effect)
- alternative choices (not evidence-based, safety not established)
 - black cohosh, phytoestrogens, St. John's wort, ginkgo biloba, valerian, evening primrose oil, ginseng, Don Quai

Hormone Replacement Therapy (HRT)

- see [Family Medicine](#), FM41
- primary indication is treatment of menopausal symptoms (vasomotor instability)
- keep doses low (e.g. 0.3 mg Premarin®) and duration of treatment short (<5 years)

HRT Components

- estrogen
 - oral or transdermal (e.g. patch, gel)
 - transdermal preferred for women with hypertriglyceridemia or impaired hepatic function
 - low-dose (e.g. 0.3 mg Premarin®/25 µg Estradot® patch)
- progestin
 - given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

Table 11. Examples of HRT Regimens

HRT Regimen	Estrogen Dose	Progestin Dose	Notes
Unopposed Estrogen	CEE 0.625 mg PO OD	None	If no intact uterus
Standard-dose	CEE 0.625 mg PO OD	MPA 2.5 mg PO OD	Withdrawal bleeding may occur in a spotty, unpredictable manner Usually abates after 6-8 months due to endometrial atrophy Once patient has become amenorrheic on HRT, significant subsequent bleeding episodes require evaluation (endometrial biopsy)
Standard-dose Cyclic	CEE 0.625 mg PO OD	MPA 5-10 mg PO days 1-14 only	Bleeding occurs monthly after day 14 of progestin (can continue for years) PMS-like symptoms (breast tenderness, fluid retention, headache, nausea) are more prominent with cyclic HRT
Pulsatile	CEE 0.625 mg PO OD	MPA low-dose	3 days on, 3 days off
Transdermal	Estroderm®-Estradiol 0.05 mg/d or 0.1 mg/d Estalis®-Estradiol® 140 µg/d or 250 µg/d	Estroderm®-MPA 2.5 mg PO OD Estalis®-NEA 50 µg/d	Use patch twice weekly Can use oral progestins (Estroderm®) Combined patches available (Estalis®)

CEE = conjugated equine estrogen (e.g. Premarin®); MPA = medroxyprogesterone acetate (e.g. Provera®); NEA = norethindrone acetate
Consider lower dose regimens, PREMPRO® 0.45/1.5 (Premarin 0.45 mg and Provera 1.5 mg)

Side Effects of HRT

- abnormal uterine bleeding
- mastodynia – breast tenderness
- edema, bloating, heartburn, nausea
- mood changes (progesterone)
- can be worse in progesterone phase of combined therapy

Contraindications to HRT

- absolute
 - acute liver disease
 - undiagnosed vaginal bleeding
 - known or suspected uterine cancer/breast cancer
 - acute vascular thrombosis or history of severe thrombophlebitis or thromboembolic disease

Menopause Pathophysiology

Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)

↓
Less estrogen is produced

↓
Decreased negative feedback on hypothalamic-pituitary-adrenal axis

↓
Increased FSH and LH

↓
Stromal cells continue to produce androgens as a result of increased LH stimulation

Absolute Contraindications to HRT

ABCD

Acute liver disease
Breast cancer (undiagnosed)
Cancer (breast/uterine)
DVT (thromboembolic disease)

Excerpt from the SOGC 2006 Menopause Consensus Report

The primary indication for HRT is for the management of moderate to severe menopausal symptoms. HRT should be prescribed at the lowest effective dose for the appropriate duration to achieve treatment goals.

- relative
 - pre-existing uncontrolled hypertension
 - uterine fibroids and endometriosis
 - familial hyperlipidemias
 - migraine headaches
 - family history of estrogen-dependent cancer
 - chronic thrombophlebitis
 - diabetes mellitus (with vascular disease)
 - gallbladder disease, hypertriglyceridemia, impaired liver function (consider transdermal estrogen)
 - fibrocystic disease of the breasts

WOMEN'S HEALTH INITIATIVE (WHI) (launched in 1991)

- two non-randomized studies investigating health risks and benefits of hormone therapy in healthy postmenopausal women 50-79 years old; the WHI Extension Study, involving follow-up health tracking without intervention, is due to last through 2010
 - continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg OD) in 16,608 women with an intact uterus
 - ♦ originally designed to run 8.5 years – stopped early after 5.2 years (July 2002) because the evidence for harm (breast cancer, CHD, stroke, PE) outweighed benefit (fracture reduction, colon cancer reduction)
 - estrogen-alone (CEE 0.625 mg) in 10,739 women with a previous hysterectomy also stopped early (February 2004 instead of March 2005) because of increased stroke risk and no heart disease benefit
- benefits and risks reported as number of cases per 10,000 women each year

HRT Benefits

- protective against osteoporotic fractures (recommended as 2nd line treatment only)
 - hip fractures – 5 fewer cases with combined HRT (6 fewer cases with estrogen-alone)
 - all fractures – 47 fewer cases with combined HRT
- colon cancer – 6 fewer cases with combined HRT (1 additional case with estrogen-alone)

HRT Risks

- invasive breast cancer – 8 additional cases with combined HRT
 - risk comparable to being 20% overweight, lacking regular exercise, fewer pregnancies after 30 years of age, reduced breastfeeding, excessive alcohol or cigarette use
 - NO increased risk with estrogen-alone (7 **fewer** cases)
- coronary heart disease – 7 additional MIs with combined HRT
 - no significant difference in cardiac deaths between treatment and control groups
 - NO elevated heart risks if used immediately after menopause (~45-55 years of age), or with estrogen-alone (5 **fewer** cases)
- DVTs or PEs – 18 additional cases with combined HRT
 - 9 additional cases for women taking estrogen-alone
- stroke – 8 additional cases with combined HRT (not statistically significant)
 - 12 additional cases with estrogen-alone
- dementia and mild cognitive impairment (WHI Memory Score)
 - women taking estrogen-alone before 65 years of age were less likely to develop dementia, **however** there was a 50% **increased** risk of developing dementia when taken after 65 years of age (those taking combined HRT were at even greater risk)
 - “window of opportunity” hypothesis: early use of estrogen (before pre-dementia changes) protects the healthy brain; in older women, where changes have already begun, use of estrogen accelerates the dementia process
- there were no significant differences in overall mortality or cause of death between treatment and placebo groups

Urogynecology

Pelvic Relaxation/Prolapse

Pelvic Relaxation/Prolapse

Protrusion of pelvic organs into or out of the vagina.

Etiology

- relaxation, weakness, or defect in the cardinal and uterosacral ligaments which normally maintain the uterus in an anteflexed position and prevent it from descending through the urogenital diaphragm (i.e. levator ani muscles)
- related to:
 - vaginal childbirth
 - aging
 - decreased estrogen (post-menopause)
 - following pelvic surgery
 - increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
 - congenital (rarely)
 - ethnicity (Caucasian women > Asian or African women)
 - collagen disorders

GENERAL CONSERVATIVE TREATMENT

(for pelvic relaxation/prolapse and urinary incontinence)

- Kegel exercises
- local vaginal estrogen therapy
- vaginal pessary

Table 12. Pelvic Prolapse

Type	Clinical Features	Treatment
Uterine Prolapse (Protrusion of cervix and uterus into vagina)	<ul style="list-style-type: none"> • Groin/back pain (stretching of uterosacral ligaments) • Feeling of heaviness/pressure in the pelvis <ul style="list-style-type: none"> • Worse with standing, lifting • Worse at the end of the day • Relieved by lying down • Ulceration/bleeding (particularly if hypoestrogenic) • \pm urinary incontinence 	<ul style="list-style-type: none"> • See <i>General Conservative Treatment</i>, above • Vaginal hysterectomy \pm surgical prevention of vault prolapse • Consider additional surgical procedures if urinary incontinence, cystocele, rectocele, and/or enterocele are present
Vault Prolapse (Protrusion of apex of vaginal vault into vagina, post-hysterectomy)		<ul style="list-style-type: none"> • See <i>General Conservative Treatment</i>, above • Sacralcolpopexy (vaginal vault suspension), sacrospinous fixation, or uterosacral ligament suspension
Cystocele (Protrusion of bladder into the anterior vaginal wall)	<ul style="list-style-type: none"> • Frequency, urgency, nocturia • Stress incontinence • Incomplete bladder emptying \pm associated increased incidence of urinary tract infections – may lead to renal impairment 	<ul style="list-style-type: none"> • See <i>General Conservative Treatment</i>, above • Anterior colporrhaphy ("anterior repair") • Consider additional/alternative surgical procedure if documented urinary stress incontinence
Rectocele (Protrusion of rectum into posterior vaginal wall)	<ul style="list-style-type: none"> • Straining/digitation to evacuate stool • Constipation 	<ul style="list-style-type: none"> • See <i>General Conservative Treatment</i>, above • Also laxatives and stool softeners • Posterior colporrhaphy ("posterior repair"), plication of endopelvic fascia and perineal muscles approximated in midline to support rectum and perineum (can result in dyspareunia)
Enterocele (Prolapse of small bowel in upper posterior vaginal wall)		<ul style="list-style-type: none"> • Similar to hernia repair • Contents reduced, neck of peritoneal sac ligated, uterosacral ligaments, and levator ani muscles approximated

**Grading of Pelvic Organ Prolapse**

- 0 = no descent during straining
- 1 = distal portion of prolapse > 1 cm above level of hymen
- 2 = distal portion of prolapse ≤ 1 cm above or below level of hymen
- 3 = distal portion of prolapse > 1 cm below level of hymen but without complete vaginal eversion
- 4 = complete eversion of total length of lower genital tract
- **Procidentia:** failure of genital supports and complete protrusion of uterus through the vagina

The only **true** hernia of the pelvis is an **ENTEROCELE** because peritoneum herniates with the small bowel.

**Figure 14. Pelvic Prolapse**

Urinary Incontinence

- see Urology, U5

Stress Incontinence

Involuntary loss of urine with increased intra-abdominal pressure (coughing, laughing, sneezing, walking, running).

The gold standard diagnostic test for urinary incontinence is multichannel urodynamics. A large proportion of cases are correctly diagnosed from clinical history alone and this can be supplemented with patient urinary and intake diaries.

Health Technol Assess 2006; 10(6):1-132.

STRESS INCONTINENCE

Risk Factors for Stress Incontinence in Women

- pelvic prolapse
- pelvic surgery
- vaginal delivery
- hypoestrogenic state (post-menopause)
- age
- smoking
- neurological/pulmonary disease

Treatment

- see *General Conservative Treatment*, GY35
- surgical
 - tension-free vaginal tape (TVT), tension-free obturator tape (TOT), prosthetic/fascial slings or retropubic bladder suspension (Burch or Marshall-Marchetti-Krantz procedures)

Urge Incontinence

Urine loss associated with an abrupt, sudden urge to void.

Rule Out Neurological Causes of Urge Incontinence

Multiple sclerosis
Slipped disc
Diabetes mellitus

URGE INCONTINENCE

Definition

- urine loss associated with an abrupt, sudden urge to void
- “overactive bladder”
- diagnosed based on symptoms

Etiology

- idiopathic (90%)
- detrusor muscle overactivity (“detrusor instability”)

Associated Symptoms

- frequency, urgency, nocturia, leakage

Treatment

- behaviour modification (reduce caffeine/liquid, smoking cessation, regular voiding schedule)
- Kegel exercises
- medications
 - anticholinergics – oxybutinin (Ditropan®), tolterodine (Detrol®)
 - tricyclic antidepressants – imipramine

Gynecological Oncology

Uterus

ENDOMETRIAL CARCINOMA

Epidemiology

- most common gynecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of women develop endometrial carcinoma during lifetime
- mean age is 60 years
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5-year survival for stage I disease
- overall 5-year survival for all stages is 70-80%

Classification

- Type I – endometrioid adenocarcinoma (~80% of cases)
- Type II – serous, clear cell carcinomas (~15% of cases)

Incidence of Malignant Gynecological Lesions in North America
endometrium > ovary > cervix > vulva
> vagina > fallopian tube

Risk Factors

- Type I: excess estrogen (estrogen unopposed by progesterone)
 - obesity
 - PCOS
 - unbalanced HRT (balanced HRT is actually protective)
 - nulliparity
 - late menopause
 - estrogen-producing ovarian tumours (e.g. granulosa cell tumours)
 - HNPCC (hereditary non-polyposis colorectal cancer)/Lynch II syndrome
 - tamoxifen
- Type II: not estrogen related
 - possibly tamoxifen

Clinical Features

- Type I: postmenopausal bleeding in majority, abnormal uterine bleeding in majority of affected pre-menopausal women (menorrhagia, intermenstrual bleeding)
- Type II: may not present with bleeding in early stage, more likely to present with advanced stage disease with symptoms like ovarian cancer (i.e. bloating, bowel dysfunction, pelvic pressure)

Table 13. FIGO Staging of Endometrial Cancer

Stage	Description	Stage	Description
I	Confined to corpus	IV	Invasion of bladder \pm bowel mucosa \pm distant metastases
IA	No or less than half myometrial invasion	IVA	Invasion of bladder \pm bowel mucosa
IB	Invades through \geq one half of myometrium	IVB	Distant mets, including intra-abdominal mets \pm inguinal LNs
II	Tumour invades cervical stroma, but does not extend beyond uterus*		
III	Local and/or regional spread of the tumour		
IIIA	Invasion of serosa, corpus uteri \pm adnexae		
IIIB	Vaginal \pm parametrial involvement		
IIIC	Metastasis to pelvic \pm para-aortic LNs		
IIIC1	Positive pelvic LN		
IIIC2	Positive para-aortic LN \pm positive pelvic LNs		

FIGO: International Federation of Gynecology and Obstetrics

*Note: endocervical glandular involvement is now considered as Stage I (previously Stage II)

Investigations

- endometrial sampling:
 - office endometrial biopsy
 - D&C \pm hysteroscopy
- \pm pelvic ultrasound (in women where adequate endometrial sampling not feasible without invasive methods)
 - not acceptable as alternative to pelvic exam or endometrial sampling to rule out cancer

Spread

- most common is direct extension
- lymphatic spread to pelvic and para-aortic nodes
- transubal dissemination to peritoneal cavity
- hematogenous spread (usually to lungs, liver)

Treatment

- surgical: hysterectomy/bilateral salpingo-oophorectomy (BSO) and pelvic washings \pm pelvic and para-aortic node dissection \pm omentectomy
 - goals: diagnosis, staging, treatment, defining optimal adjuvant treatment
 - laparoscopic approach associated with improved quality of life (optimal for most patients)
- adjuvant radiotherapy (for improved local control in patients at risk for local recurrence) and adjuvant chemotherapy (in patients at risk for distant recurrence or with metastatic disease) – based on presence of poor prognostic factors in definitive pathology
- chemotherapy often used for recurrent disease (especially if high grade or aggressive histology)
- hormonal therapy: progestins can be used for recurrent disease (especially if low grade)

UTERINE SARCOMA

- rare: 2-6% of all uterine malignancies
- arise from stromal components (endometrial stroma, mesenchymal or myometrial tissues)
- behave more aggressively and are associated with poorer prognosis than endometrial carcinoma; 5-year survival – 35%
- vaginal bleeding is most common presenting symptom

**Risk Factors for Endometrial Cancer****COLD NUT**

Cancer (ovarian, breast, colon)

Obesity

Late menopause

Diabetes mellitus

Nulliparity

Unopposed estrogen: PCOS, anovulation, HRT

Tamoxifen: chronic use

Postmenopausal bleeding = endometrial cancer until proven otherwise.
95% present with vaginal bleeding.

An endometrial thickness of 5 mm or more is considered abnormal in a postmenopausal woman with vaginal bleeding.

True Pelvis

Area of pelvis between pelvic inlet and outlet, i.e. it does not include the abdominal contents in the pelvis found above the pelvic inlet.

**Prognostic Factors**

1. Grade (histological differentiation)
2. Vascular, lymphatic involvement
3. Progesterone-receptor levels
4. Myometrial invasion

**Uterine Sarcoma – Symptoms****BAD-P**

Bleeding

Abdominal distention

Foul smelling vaginal Discharge

Pelvic Pressure

1. Mixed Müllerian Mesodermal Tumour (Carcinosarcoma)

- most common type of uterine sarcoma (43%)
- both epithelial and sarcomatous malignant elements are present
- tend to form bulky polypoid masses that often fill the uterine cavity and extend into or through the endocervical canal – often have extrauterine disease at presentation

Treatment

- usually treated as “very high grade endometrial carcinoma” since behaviour and treatment similar (i.e. surgical staging, adjuvant chemotherapy and radiation)

2. Leiomyosarcoma

- account for one third of uterine sarcomas
- when occurs, often coexists with benign leiomyomata (fibroids)
- 50% of time, leiomyosarcomata arise within a fibroid (“sarcomatous degeneration”)
- average age of presentation is 55 years but may present in pre-menopause
- histologic distinction from leiomyoma
 - increased mitotic count (>10 mitoses/10 high power fields)
 - tumour necrosis
 - cellular atypia
- often diagnosed postoperatively after uterus removed for presumed fibroids

Clinical Features

- “rapidly” enlarging fibroids in a pre-menopausal woman
- enlarging fibroids in a postmenopausal woman

Treatment

- hysterectomy/BSO usually without node dissection due to high propensity for vascular spread (i.e. liver/lung metastases)
- adjuvant chemotherapy may be used if tumour has spread beyond uterus, for palliation
- radiation therapy does not improve local control or survival
- poor outcome overall, even for early stage disease

3. Endometrial Stromal Sarcoma

- usually presents in perimenopausal or postmenopausal women with abnormal uterine bleeding
- diagnosed by histology of endometrial biopsy or D&C

Treatment

- hysterectomy/BSO (ALWAYS remove ovaries as ovarian hormones may stimulate growth)
- adjuvant therapy based on stage and histologic features (hormones and/or radiation)
- hormonal therapy (progestins) may be used for metastatic disease in low grade ESS

A rapidly enlarging uterus, especially in a postmenopausal woman, should prompt consideration of leiomyosarcoma.

Ovary

BENIGN OVARIAN TUMOURS

- see Table 14
- most are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
- pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
- peritoneal irritation may result from an infarcted tumour – rare

MALIGNANT OVARIAN TUMOURS

- see Table 14

Epidemiology

- lifetime risk 1.4% (1/70)
- in women >50 years, more than 50% of ovarian tumours are malignant
- causes more deaths in North America than all other gynecologic malignancies combined
- 4th leading cause of cancer death in women
- 65% epithelial; 35% non-epithelial
- 5-10% of epithelial ovarian cancers are related to hereditary predisposition

Ovarian Tumour Markers

Epithelial cell – CA-125

Stromal

Granulosa cell – inhibin

Sertoli-Leydig – androgens

Germ cell

Dysgerminoma – LDH

Yolk sac – AFP

Choriocarcinoma – beta-hCG

Immature Teratoma – none

Embryonal cell – AFP + beta-hCG

Risk Factors (for **epithelial** ovarian cancers)

- nulliparity
- early menarche/late menopause
- age
- family history of breast, colon, endometrial, ovarian cancer
- race: Caucasian

Protective Factors (for **epithelial** ovarian cancers)

- OCP: likely due to ovulation suppression (significant reduction in risk even after 1 year of use)
- pregnancy/breastfeeding
- tubal ligation (recently questioned)
- hysterectomy (without removal of ovaries)
- bilateral salpingo-oophorectomy (prophylactic surgery performed for this reason in women with known high risk – i.e. BRCA mutation carriers)

Clinical Features

- most women with epithelial ovarian cancer present with advanced stage disease since often “asymptomatic” until disseminated disease
 - vague non-specific symptoms associated with early stage disease
- when present, non-specific symptoms may include:
 - vague abdominal symptoms (nausea, bloating, dyspepsia, anorexia, early satiety)
 - symptoms of mass effect
 - ♦ increased abdominal girth – from ascites or tumour itself
 - ♦ urinary frequency
 - ♦ constipation
 - ♦ fluid wave – signs of ascites
 - postmenopausal bleeding; irregular menses if pre-menopausal (rare)

Low Malignant Potential (also called “Borderline”) Tumours

- pregnancy, OCP and breastfeeding are found to be protective factors
- ~15% of all epithelial ovarian tumours
- tumour cells display malignant characteristics histologically, but no invasion is identified
- able to metastasize, but not commonly
- treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
 - NO proven benefit of chemotherapy
- generally slow growing, excellent prognosis
 - 5-year survival >99%
 - recurrences tend to occur late, may be associated with low grade serous carcinoma

**Risk/Protective Factors for Epithelial Ovarian Cancer****NO CHILD**

Nulliparity
OCP, breast-feeding, tubal ligation, hysterectomy (protective)
Caucasian
Family History
Increasing age (>40)
Late menopause
Delayed child-bearing

Any adnexal mass in postmenopausal women should be considered malignant until proven otherwise.

Most (70%) epithelial ovarian cancers present at stage III disease.

Diagnosis requires surgical pathology.

Table 14. Ovarian Tumours

Type	Description	Presentation	Ultrasound/Cytology	Treatment
FUNCTIONAL TUMOURS (all benign)				
Follicular cyst 	Follicle fails to rupture during ovulation	Usually asymptomatic May rupture, bleed, tort, infarct causing pain ± signs of peritoneal irritation	4-8 cm mass, unilocular, lined with granulosa cells	Symptomatic or suspicious masses warrant surgical exploration Otherwise if <6 cm, wait 6 weeks then re-examine as cyst usually regresses with next cycle OCP (ovarian suppression) – will prevent development of new cysts Treatment usually laparoscopic
Lutein cyst	Corpus luteum fails to regress after 14 days, becoming cystic or hemorrhagic	More likely to cause pain than follicular cyst May delay onset of next period	Larger (10-15 cm) and firmer than follicular cysts	Same as for follicular cysts
Theca-lutein cyst	Due to atretic follicles stimulated by abnormal β-hCG levels	Associated with molar pregnancy, ovulation induction with clomiphene		Conservative Cyst will regress as β-hCG levels fall
Luteoma of pregnancy	Usually bilateral Due to prolonged elevation of β-hCG	Associated with multiple pregnancy		Same as for theca-lutein Regresses postpartum
Endometrioma	See <i>Endometriosis</i> , GY15			
Polycystic Ovaries	See <i>PCOS</i> , GY23			
BENIGN GERM-CELL TUMOURS				
Benign cystic teratoma (dermoid) 	Single most common ovarian germ cell neoplasm Elements of all 3 cell lines, contains dermal appendages (sweat and sebaceous glands, hair follicles, teeth)	May rupture, twist, infarct 20% bilateral 20% occur outside of reproductive years	Smooth-walled, mobile, unilocular Ultrasound may show calcification which is pathognomonic	Treatment usually laparoscopic cystectomy; may recur

Table 14. Ovarian Tumours (continued)

Type	Description	Presentation	Ultrasound/Cytology	Treatment
MALIGNANT GERM-CELL TUMOURS				
General Information	Rapidly growing, 2-3% of all ovarian cancers	Usually children and young women (<30 years)		Surgical resection (often conservative unilateral salpingo-oophorectomy ± nodes) ± chemo
Dysgerminoma	Produces lactate dehydrogenase (LDH)	10% bilateral		Usually very responsive to chemotherapy, therefore complete resection is not necessary for cure
Immature teratoma	No tumour marker identified			
Yolk sac tumour	Produces alpha fetoprotein (AFP) Rare	Unilateral		More aggressive subtype, often need chemo (BEP)
Embryonal	Produces AFP and β-hCG			
Carcinoma	Rare			
Choriocarcinoma	Produces β-hCG			
EPITHELIAL OVARIAN TUMOURS (may be benign, malignant or borderline)				
General Information	Derived from mesothelial cells lining peritoneal cavity Classified based on histologic type 80-85% of all ovarian neoplasms (includes malignant)		Varies depending on subtype	Benign Cystectomy vs. unilateral salpingo-oophorectomy Malignant 1. Early stage (stage 1): BSO ± hysterectomy ± omentectomy ± peritoneal washings ± staging (peritoneal biopsies + node dissection) ± adjuvant chemotherapy 2. Advanced stage: Upfront cytoreductive (debulking) surgery vs. neoadjuvant chemotherapy Adjuvant chemotherapy: IP chemotherapy vs. IV Carbo/Taxol
Serous	Most common ovarian tumour 50% of all ovarian cancers 75% of epithelial tumours 70% benign	20-30% bilateral	Lining similar to fallopian tube epithelium Often multilocular Histologically contain Psammoma bodies (calcified concentric concretions)	
Mucinous	85% benign 20% of epithelial tumours	Rarely complicated by <i>Pseudomyxoma peritonei</i> : implants seed abdominal cavity and produce large quantities of mucin	Resembles endocervical epithelium Often multilocular May reach enormous size	Query poor response to chemotherapy Unclear role for radiation in patients with no residual disease (rare) If mucinous – remove appendix as well
Endometrioid	20% of epithelial ovarian Ca High malignant potential		Histology resembles endometrium	
Clear cell	≤1% of epithelial ovarian Ca High malignant potential		Histology resembles mesonephric cells	
Brenner tumour	≤1% of epithelial ovarian Ca Majority benign		Fibrotic tumour with transitional cell-like epithelial core	
SEX CORD STROMAL OVARIAN TUMOURS				
General Information				Surgical resection of tumour Chemotherapy may be used for metastatic disease not resectable
Fibroma (benign)	From mature fibroblasts in ovarian stroma	Non-functioning Occasionally associated with Meig's syndrome	Firm, smooth rounded tumour with interlacing fibrocytes	
Granulosa-theca cell tumours (benign or malignant)	Can be associated with endometrial cancer Inhibin is tumour marker	Estrogen-producing → feminizing effects (precocious puberty, menorrhagia, postmenopausal bleeding)	Histologic hallmark of cancer is small groups of cells known as Call-Exner bodies	
Sertoli-Leydig cell tumour (benign or malignant)	Can measure elevated androgens as tumour markers	Androgen-producing → virilizing effects (hirsutism) deep voice, recession of front hairline)		
METASTATIC OVARIAN TUMOURS				
From GI tract, breast, endometrium, lymphoma	4-8% of ovarian malignancies		Krukenberg tumour = metastatic ovarian tumour from other site (usually GI tract, commonly stomach or colon, breast) with "signet-ring" cells	

Investigation of Suspicious Ovarian Mass

- goals of management: address symptoms and optimal surgical staging of malignancy
- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist prior to surgery to facilitate optimal surgery
 - bimanual examination
 - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
 - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for pre-operative gynaecologic oncology referral (see sidebar)
- bloodwork: CA-125 for baseline, CBC, liver function tests, electrolytes, creatinine
- radiology: transvaginal U/S best to visualize ovaries; CT scan abdomen and pelvis best to look for metastatic disease
- bone scan or PET scan **not** indicated
- try to rule out other primary source if suspected based on:
 - occult blood per rectum: if positive, endoscopy ± barium enema
 - if gastric symptoms, gastroscopy ± upper GI series
 - if abnormal vaginal bleeding, endometrial biopsy to rule out concurrent endometrial cancer, colposcopy ± ECC to rule out cervical cancer if abnormal cervix
 - mammogram if breast lesion identified or risk factors present

Screening

- no effective method of mass screening
- routine CA-125 level measurements or U/S **not** recommended
 - more women suffer from false positive results than helped
- controversial in high risk groups – starting age 30, transvaginal U/S and CA-125 (no consensus on interval)
 - familial ovarian cancer (>1 first degree relative affected, BRCA-1 mutation)
 - other cancers (i.e. endometrial, breast, colon)
 - BRCA-1 or BRCA-2 mutation: may recommend prophylactic bilateral oophorectomy after age 35 or when child-bearing is completed

Table 15. FIGO Staging for Primary Carcinoma of the Ovary (Surgical Staging)

Stage	Description
I	Growth limited to the ovaries
IA	1 ovary, no ascites, no tumour on external surface, capsule intact
IB	2 ovaries, no ascites, no tumour on external surface, capsule intact
IC	1 or 2 ovaries with any of the following: capsule ruptured, tumour on ovarian surface or malignant cells in ascites
II	Growth involving one or both ovaries with pelvic extension
IIA	Extension ± metastases to uterus/tubes
IIB	Extension to other pelvic structures
IIC	II A/B with malignant cells in ascites or positive peritoneal washings
III	Tumour involving one or both ovaries with peritoneal implants outside the pelvis and/or positive retroperitoneal or inguinal nodes. Superficial liver mets is Stage III.
IIIA	Microscopic peritoneal metastasis beyond pelvis, LNs negative
IIB	Macroscopic peritoneal metastasis beyond pelvis <2 cm, LNs negative
IIC	Implant >2 cm and/or retroperitoneal or inguinal nodes
IV	Distant metastasis beyond peritoneal cavity

FIGO: International Federation of Gynecology and Obstetrics

Risk of Malignancy Index (RMI)

Moore et. al. *Am J Obst Gynecol.* May 2010.

$$RMI = U \times M \times CA-125$$

ULTRASOUND FINDINGS (1 pt for each)

- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions
- U = 1 (for U/S scores of 0 or 1)
- U = 4 (for U/S scores of 2-5)

MENOPAUSAL STATUS

- Postmenopausal: M = 4
- Pre-menopausal: M = 1

ABSOLUTE VALUE OF CA-125 SERUM LEVEL

For RMI > 200: Gynecologic Oncology referral is recommended

Causes of Elevated CA-125

- Age influences reliability of test as a tumour marker
- 50% sensitivity in early stage ovarian cancer (poor) – therefore not good for screening

MALIGNANT

- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

NON MALIGNANT

- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure

CA-125 is indicated for monitoring response to treatment.

Malignant Ovarian Tumour Prognosis

5-year Survival

- Stage I: 75-95%
- Stage II: 60-75%
- Stage III: 23-41%
- Stage IV: 11%

Cervix

BENIGN CERVICAL LESIONS

- Nabothian cyst/inclusion cyst
 - no treatment required
- endocervical polyps
 - treatment is polypectomy (office procedure)

MALIGNANT CERVICAL LESIONS

- majority are squamous cell carcinomas (95%), adenocarcinomas increasing (5%), rare subtypes include small cell, adenosquamous
- 8,000 deaths annually in North America
- annual Pap test reduces a woman's chance of dying from cervical cancer from 0.4% to 0.05%
- average age: 52 years old

Figure 15. The Cervix

Cervical cancer is caused by HPV infection.

Systematic Review of RCTs for HPV Vaccination Prophylactic Vaccination Against Human Papillomavirus Infection in Women: A Systematic Review of Randomized Controlled Trials

Rambout L, Hopkins L, Fung Kee Fung M, et al. *CMAJ* 2007; 177

Purpose: To assess the effectiveness of HPV vaccination for preventing HPV infection and precancerous cervical lesions.

Study: Systematic review of studies of prophylactic HPV vaccination.

Data Sources: MEDLINE, EMBASE, Cochrane Central Registry of Controlled Trials, and the Cochrane Library.

Patients: Of 457 studies, nine were included in the review (six of these were RCTs). A total of 40,323 females were enrolled. All participants had received HPV vaccinations that included coverage of the HPV 16 strain.

Main outcomes: Frequency of high-grade cervical lesions, persistent HPV infection, low-grade cervical lesions, external genital lesions, adverse events, and death.

Results: HPV vaccination was associated with a reduction in the frequency of high-grade cervical lesions caused by vaccine-type HPV strains compared with control groups. The HPV vaccination was also found to be efficacious in reducing persistent HPV infection, low-grade lesions, and genital warts.

Conclusion: Prophylactic vaccination of women between 15-25 years not previously infected with vaccine-type HPV strains, has been found to be efficacious in preventing HPV infection and precancerous cervical lesions.

Liquid-based Cytologic Smear vs. Conventional Pap Smear

Am J Obstet Gynecol 2001; 185(2):308-17

Purpose: To assess the cytologic diagnosis and sample adequacy of liquid-based cervical cytologic smear (ThinPrep) versus conventional Papanicolaou smear.

Study: Systematic review of prospective trials comparing ThinPrep and conventional Pap smears.

Data sources: MEDLINE, PubMed, Silver Platter were searched for literature published in English between January 1990 and April 2000. Selection criteria included split-sample (SS) and direct-to-vial (DV) (case-cohort) studies.

Patients: 25 studies met the selection criteria (n=533,039 women; 221,864 in ThinPrep group; 378,659 in conventional smear group; 67,484 in both groups)

Main outcomes: (i) Frequency of diagnoses of ASCUS, LSIL, HSIL. (ii) Adequacy of sample collection (contains squamous cells, endocervical cells, and possibly metaplastic cells).

Results: Liquid-based smears (ThinPrep) had significantly improved cytologic diagnosis of LSIL (OR = 1.27 to 2.15) and diagnosis of HSIL (OR = 2.26), but no difference in rate of diagnosis of ASCUS (OR = 1.03). Liquid-based pap smear also resulted in improved sample adequacy (OR = 1.64 to 2.11).

Conclusion: Liquid-based cytologic smears resulted in better diagnosis of cervical premalignant lesions (HSIL and LSIL) and improved sample adequacy, compared to conventional Pap smears.

Etiology

- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from squamous to columnar)
 - a new squamocolumnar junction forms as a result
- the transformation zone (TZ) is the area located between the original and the current squamocolumnar junction (Figure 15)
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia → carcinoma in situ (CIS) → invasion
- slow process (~10 years on average)
- growth is by local extension
- metastasis occurs late

Risk Factors

- HPV infection
 - see *Sexually Transmitted Infections*, GY26
 - high risk of neoplasia associated with types 16, 18
 - low risk of neoplasia associated with types 6, 11
 - >99% of cervical cancers contain one of the high risk HPV types
- smoking
- high risk behaviours (risk factors for HPV infection)
 - multiple partners
 - other STIs (HSV, trichomonas)
 - early age first intercourse
 - high risk male partner
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
 - immigrant Canadians
 - First Nations Canadians
 - geographically isolated Canadians
 - sex-trade workers
 - low socioeconomic status

Prevention: Quadrivalent HPV Recombinant Vaccine (Gardasil®)

- currently indicated for females 9 to 26 years of age for prevention of diseases caused by HPV types 6, 11, 16 and 18 (genital warts, cervical, vulvar and vaginal dysplasias and cancers)
- for optimal benefit of vaccination, should be administered before onset of sexual activity (i.e. before exposure to virus)
- administered IM at time 0, 2 and 6 months, may be given at the same time as Hep B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 days after last dose of vaccination
- side effects: pain, swelling, erythema, low grade fever
- contraindications: pregnant women and women who are nursing (limited data)

Clinical Features

- squamous cell carcinoma (SCC)
 - exophytic, fungating tumour
- adenocarcinoma
 - endophytic, with barrel-shaped cervix
- early
 - asymptomatic
 - discharge: initially watery, becoming brown or red
 - post-coital bleeding
- late
 - 80-90% present with bleeding: either post-coital, postmenopausal or irregular bleeding
 - pelvic or back pain (extension of tumour to pelvic walls)
 - bladder/bowel symptoms
- signs
 - friable, raised, reddened or ulcerated area visible on cervix

Cervical Screening Guidelines (Pap Test)

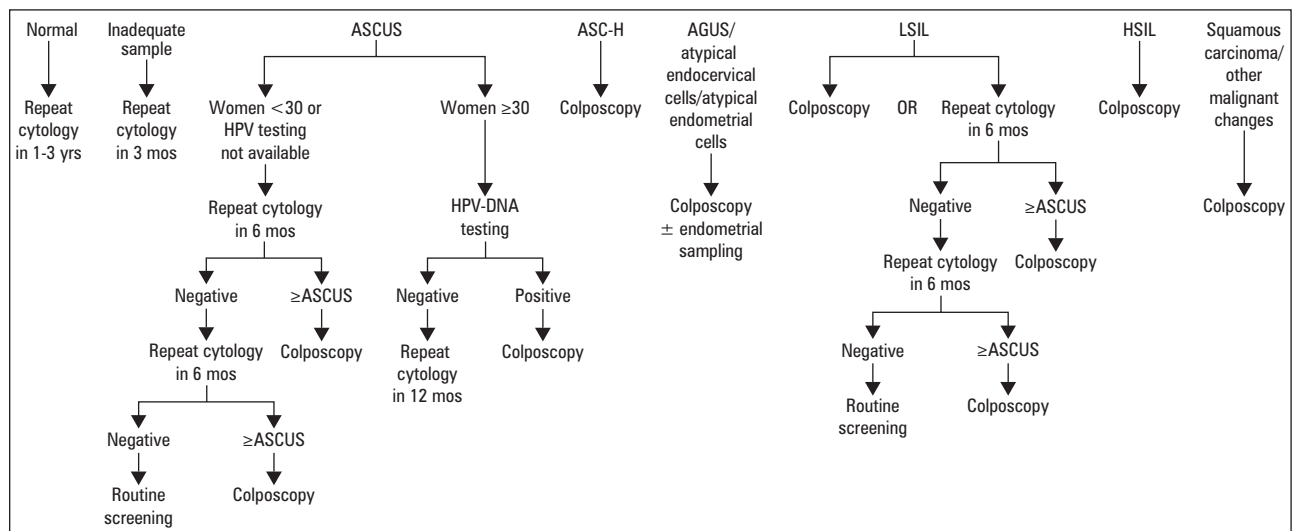

- endocervical and exocervical cell sampling (aim is to sample the TZ)
- best identifies squamous cell abnormalities, less reliable for glandular abnormalities
 - false positives 5-10%, false negatives 10-40% (for single test)
 - false negative rate 50% for existing cervical cancer
- all women: start annual screening at age 21, or 3 years after onset of vaginal intercourse
 - women ≥ 30 years: if 3 normal Paps in a row, and no previous abnormal Paps, can get screened every 2-3 years (if adequate recall mechanism in place)
 - women ≥ 70 years: if 3 normal Paps in a row and no abnormal Paps in last 10 years, can discontinue screening (if remain at low risk)
- pregnant women and women who have sex with women should follow the routine cervical screening regimen
- women who have had a hysterectomy:
 - total: discontinue screening if hysterectomy was for benign disease and no history of cervical dysplasia or HPV infection
 - subtotal: continue screening according to guidelines
- exceptions to guidelines:
 - immunocompromised (transplant, steroids, DES exposure)
 - HIV and high risk
 - previously unscreened patients

Table 16. Cytological Classification

Bethesda Grading System	Classic System/ Cervical Intraepithelial Neoplasia (CIN) Grading System
Within normal limits	Normal
Infection	Inflammatory atypia (organism)
Reactive and reparative changes	
Squamous cell abnormalities	
Atypical squamous cells of undetermined significance (ASCUS)	Squamous atypia of uncertain significance
Atypical squamous cells, cannot exclude HSIL (ASC-H)	
Low grade squamous intraepithelial lesion (LSIL)	HPV atypia or mild dysplasia (CIN I)
High grade squamous intraepithelial lesion (HSIL)	Moderate dysplasia (CIN II)
	Severe dysplasia (CIN III)
	Carcinoma in situ (CIS)
Squamous cell carcinoma (SCC)	Squamous cell carcinoma (SCC)
Glandular cell abnormalities	
Atypical glandular cells of undetermined significance (AGUS)	Glandular atypia of uncertain significance
Endocervical adenocarcinoma	Adenocarcinoma
Endometrial adenocarcinoma	
Extrauterine adenocarcinoma	
Adenocarcinoma, not otherwise specified (NOS)	

The Bethesda Classification System is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. The diagnosis of cervical intraepithelial neoplasia (CIN) or cervical carcinoma requires a tissue sample, obtained by biopsy of suspicious lesions (done during colposcopy), to make a histologic diagnosis.

**Figure 16. Decision Making Chart for Pap Test (not applicable for adolescents)**

Adapted from Ontario Cervical Screening Practice Guidelines, June 2005. Cervical screening guidelines unique to each province.

Diagnosis

- see *Colposcopy*, GY9
- apply acetic acid and identify acetowhite lesions, punctation, mosaicism, and abnormal blood vessels to guide cervical biopsy
- endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
- diagnostic excision (loop electrosurgical excision procedure, LEEP) if:
 - lesion extends into endocervical canal
 - positive ECC
 - discrepancy between Pap test results and colposcopy
 - microinvasive carcinoma
- consider cold knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including EUA), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, IVP, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy, results do not influence clinical stage

Table 17. FIGO Staging Classification of Cervical Cancer (clinical staging)

Stage	Description
I	Confined to cervix
IA	Microinvasive (diagnosed only by microscopy)
IA ₁	Stromal invasion not >3 mm deep, not >7 mm wide
IA ₂	3-5 mm deep; not >7 mm wide
IB	Clinically visible lesion confined to cervix, or microscopic lesion >IA
IB ₁	Clinically visible lesion ≤4 mm in greatest dimension
IB ₂	Clinically visible lesion >4 mm in greatest dimension
II	Beyond uterus but not to the pelvic wall or lower 1/3 of vagina
IIA	No obvious parametrial involvement
IIA ₁	Clinically visible lesion ≤4 mm in greatest dimension
IIA ₂	Clinically visible lesion >4 mm in greatest dimension
IIB	Obvious parametrial involvement
III	Extends to pelvic wall, and/or involves lower 1/3 of vagina and/or causes hydronephrosis or non-functioning kidney
IIIA	Involves lower 1/3 vagina but no extension into pelvic side wall
IIIB	Involves lower 1/3 vagina and extends into pelvic side wall and/or hydronephrosis or non-functioning kidney
IV	Carcinoma has extended beyond true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum
IVA	Spread of the growth to adjacent organs
IVB	Distant metastases

Table 18. Treatment of Patients with Cervical Dysplasia and Cervical Cancer

	Treatment
CIN I (LSIL)	Observe with regular cytology (every 6 months) Many lesions will regress or disappear (60%) Colposcopy if positive on 2 consecutive smears Lesions which progress should have area excised by either LEEP, laser, cryotherapy or cone biopsy (with LEEP, tissues obtained for histological evaluation)
CIN II and CIN III (HSIL)	Colposcopy referral Ablation or excision therapy: LEEP, laser, cryotherapy, cone excision, cautery Hysterectomy – only if no desire for future childbearing
Stage IA ₁ (=microinvasive SCC if: <3 mm invasion and no CLS)	Cervical conization if future fertility desired Simple hysterectomy if future fertility is not desired
Stage IA ₂ , IB ₁	Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study) Advantage is that ovaries can be spared if pre-menopausal For fertility preservation, may have radical trachelectomy and nodes instead of radical hysterectomy for early-stage disease Concurrent chemoradiation therapy if adverse prognostic factors on radical surgical specimen, poor surgical candidate, or if significantly adverse prognostic factors present at time of diagnosis
Stages IB ₂ (>4 cm), II, III, IV	Concurrent chemoradiation therapy

Abnormal Pap Tests in Pregnancy

- incidence – 1/2,200
- Pap test at all initial prenatal visits
 - if abnormal Pap or suspicious lesion, refer to colposcopy
- if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
- if invasive cancer ruled out, management of dysplasia deferred until after completion of pregnancy (may deliver vaginally)

Cervical cancer is most prevalent in developing countries and therefore is the only gynecologic cancer that uses clinical staging. This facilitates consistent international staging with countries that do not have technologies such as CT and MRI.

Cervical Cancer Prognosis

5 Year Survival

- Stage 0: 99%
- Stage I: 75%
- Stage II: 55%
- Stage III: 30%
- Stage IV: 7%
- Overall: 50-60%

- if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
 - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility) or concurrent chemoradiation therapy
 - recommendations in T2/T3: delay of therapy until viable fetus and C/S for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Vulva

BENIGN VULVAR LESIONS

Non-Neoplastic Disorders of Vulvar Epithelium

- biopsy is necessary to make diagnosis and/or rule out malignancy
- **hyperplastic dystrophy** (squamous cell hyperplasia)
 - surface thickened and hyperkeratotic
 - pruritus most common symptom
 - typically postmenopausal women
 - treatment: 1% fluorinated corticosteroid ointment bid for 6 weeks
- **lichen sclerosis**
 - subepithelial fat becomes diminished, labia become thin and atrophic, membrane-like epithelium, labial fusion
 - pruritus, dyspareunia, burning
 - 'figure of 8' distribution
 - most common in postmenopausal women but can occur at any age
 - treatment: ultrapotent topical steroid 0.05% clobetasol x 2-4wks then taper down
- **mixed dystrophy** (lichen sclerosis with epithelial hyperplasia)
 - hyperkeratotic areas with areas of thin, shiny epithelium
 - treatment: fluorinated corticosteroid ointment

Any suspicious lesion of the vulva should be biopsied.

Tumours

- papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNANT VULVAR LESIONS

Epidemiology

- 5% of genital tract malignancies
- 90% squamous cell carcinoma; remainder melanomas, basal cell carcinoma, Paget's disease, Bartholin's gland carcinoma
 - Type I disease: HPV-related disease (50-70%)
 - ♦ more likely in younger women
 - ♦ 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
 - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
 - ♦ usually postmenopausal women

Risk Factors

- HPV infection (see above)
- VIN (vulvar intraepithelial neoplasia): precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
 - progression to cancer rarely occurs with appropriate management
 - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects [if required]) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)

Clinical Features

- many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus or lesion most common
- less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
- patterns of spread
 - local
 - groin lymph nodes (usually inguinal → pelvic nodes)
 - hematogenous

Investigations

- physical examination
- ± colposcopy
- ALWAYS biopsy any suspicious lesion

Table 19. FIGO Staging Classification and Treatment of Vulvar Cancer

Stage	Description	Treatment
0	Intraepithelial neoplasia (VIN), carcinoma in situ	Local excision/superficial vulvectomy Laser ablation Local immunotherapy (imiquimod)
I	Tumour confined to vulva	Radical local excision + groin node dissection if >1 mm invasion
IA	≤2 cm lesion, confined to vulva, perineum ± stromal invasion ≤1 mm, no LN involment	Sentinel node dissection acceptable if lesion <4 cm and no suspicious nodes on examination
IB	>2 mm lesion or stromal invasion >1 mm, no LNs, confined to vulva or perineum	
II	Tumour any size with adjacent extension to 1/3 lower urethra, 1/3 lower vagina or anus Negative inguino-femoral LNs	Individualized Radical surgical excision ± chemoradiation
III	II plus positive inguino-femoral LNs	Individualized
IIIA	1 LN met (≥5 mm) or 1-2 LN mets (<5 mm)	Chemoradiation ± radical surgical excision
IIIB	2 LNs (≥5 mm) or >3 LNs mets (<5 mm)	
IIIC	Positive LNs with extracapsular spread	
IV	Regional (2/3 upper urethra, 2/3 upper vagina) spread or distant spread	Palliative therapy Individualized
IVA	(i) Spread to upper urethra ± vaginal mucosa, bladder, rectal mucosa or fixed to pelvic bone (ii) Fixed or ulcerated inguino-femoral LN	Chemoradiation ± radical surgical excision
IVB	Distant mets including pelvic LN	

Prognosis

- depends on stage and particularly nodal involvement (single most important predictor followed by tumour size)
- lesions >4 cm associated with poorer prognosis
- toxicities of therapy common
 - surgical site infection
 - lymphedema
 - radiation fibrosis, cystitis, proctitis
- overall 5-year survival rate: 79%

Vagina

BENIGN VAGINAL LESIONS

- **inclusion cysts**
 - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
 - no treatment required
- **endometriosis**
 - dark lesions that tend to bleed at time of menses
 - treatment is excision
- **Gartner's duct cysts**
 - remnants of Wolffian duct, seen along side of cervix
 - treatment conservative unless symptomatic
- **urethral diverticulum**
 - can lead to recurrent urethral infection, dyspareunia
 - surgical correction if symptomatic

MALIGNANT VAGINAL LESIONS**Risk Factors**

- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

Investigations

- cytology
 - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy!)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are actually metastatic from one of these sites)
- staging (see Table 20)

VAIN (Vaginal Intra-Epithelial Neoplasia)

- grades: analogous to cervical dysplasia
- treatment
 - must rule out invasive cancer via biopsies and colposcopy prior to conservative treatment
 - laser ablation vs. surgical excision vs. local immunotherapy (e.g. imiquimod)

Squamous Cell Carcinoma (SCC)

- 80-90% of vaginal cancer
- 2% of gynecological malignancies
- most common site is upper 1/3 of posterior wall of vagina
- 5-year survival – 42%
- clinical features
 - asymptomatic
 - painless discharge and bleeding
 - vaginal discharge (often foul-smelling)
 - vaginal bleeding especially during/post-coitus
 - urinary and/or rectal symptoms 2° to compression
- treatment
 - usually concurrent chemoradiation therapy for 1° vaginal cancer
 - consider radical hysterectomy/upper vaginectomy if early stage lesion and young patient

Adenocarcinoma

- most are metastatic, usually from the cervix, endometrium, ovary, or colon
- most primaries are clear cell adenocarcinomas
- 2 types: non-DES and DES syndrome
- management as for SCC

Diethylstilbestrol (DES) Syndrome

- fetal exposure to DES (due to maternal use) predisposes to cervical or vaginal clear cell carcinoma, occurs in 30-95% of exposed females
- if exposed, <1 in 1,000 risk of developing clear cell adenocarcinoma
- clinical features
 - adenosis is persistent Müllerian type glandular epithelium in vagina
 - DES exposure associated with malformations of upper vagina, cervix, and interior of uterus (T-shaped); cockscomb or hooded cervix, cervical collar, and pseudopolyps of cervix
- patients with DES exposure should have annual Pap tests (cervix and vagina) and digital vaginal exam for subepithelial masses
 - if any abnormality, refer for colposcopy

Table 20. FIGO Staging Classification of Vaginal Cancer (Clinical Staging)

Stage	Description
0	Intraepithelial neoplasia (VAIN), carcinoma in situ
I	Limited to the vaginal wall
II	Involves subvaginal tissue, NO pelvic wall extension
III	Pelvic wall extension
IV	Extension beyond true pelvis OR bladder/rectum involvement
IVA	Bladder ± rectal mucosal spread ± extension beyond true pelvis
IVB	Spread to distant organs

Prognosis
5 Year Survival Rates
 Stage I 70%
 Stage II 40%
 Stage III 30%
 Stage IV 15-20%

Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)
- usually adenocarcinoma
- analogous to ovarian cancer (may be implicated in pathogenesis of ovarian cancer)
- more common in fifth and sixth decade

Clinical Features

- classic triad present in minority of cases, but very specific
 - watery discharge (most specific) = “hydrops tubae profluens”
 - vaginal bleeding or discharge in 50% of patients
 - crampy lower abdominal/pelvic pain
- most patients present with a pelvic mass (see *Ovarian Cancer*, GY38 for guidelines regarding diagnosis/investigation)

Treatment

- as for malignant ovarian tumours

Classic Triad (<15% of patients)
 1. Watery vaginal discharge
 2. Pelvic pain
 3. Vaginal bleeding

Current hypotheses suggest epithelial serous ovarian cancer originates from malignant fallopian tube cells.

With development of hypertension early in pregnancy (i.e. <20 weeks), think gestational trophoblastic disease!

Gestational Trophoblastic Disease/Neoplasia (GTD/GTN)

- refers to a spectrum of proliferative abnormalities of the trophoblast

Epidemiology

- 1/1000 pregnancies
- marked geographic variation – as high as 1/125 in Taiwan
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

HYDATIDIFORM MOLE (Benign GTD)

- **complete mole**
 - most common type of hydatidiform mole
 - diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues or membranes present
 - 46XX or 46XY, chromosomes completely of paternal origin (90%)
 - 2 sperm fertilize empty egg or 1 sperm with reduplication
 - 15-20% risk of progression to malignant sequelae
 - risk factors
 - ♦ geographic (South East Asia most common)
 - ♦ others (maternal age >40 years, β -carotene deficiency, vitamin A deficiency) – not proven
 - clinical features
 - ♦ often present during apparent pregnancy with abnormal symptoms/findings:
 - vaginal bleeding (97%)
 - excessive uterine size for LMP (51%)
 - theca-lutein cysts >6 cm (50%)
 - pre-eclampsia (27%)
 - hyperemesis gravidarum (26%)
 - hyperthyroidism (7%)
 - beta-hCG >100,000 mIU/mL
 - no fetal heart detected
- **partial (or incomplete) mole**
 - hydropic villi and focal trophoblastic hyperplasia are associated with fetus or fetal parts
 - often triploid (XXY, XYY, XXX) with chromosome complement from both parents
 - ♦ usually related to single ovum fertilized by two sperm
 - low risk of progression to malignant sequelae (<4%)
 - associated with fetus, which may be growth-restricted and/or have multiple congenital malformations
 - clinical features
 - ♦ typically present similar to threatened/spontaneous/missed abortion
 - ♦ pathological diagnosis often made after D&C

Investigations

- quantitative beta-hCG levels (tumour marker) abnormally high for gestational age
- U/S findings:
 - if complete: no fetus (classic “snow storm” due to swelling of villi)
 - if partial: molar degeneration of placenta \pm fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high risk of developing persistent GTN post-evacuation
 - local uterine invasion as high as 31%
 - beta-hCG >100,000
 - excessive uterine size
 - prominent theca-lutein cysts

Treatment

- suction D&C with sharp curettage and oxytocin
- Rhogam® if Rh negative
- consider hysterectomy (if patient no longer desires fertility)
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

Follow-up

- contraception required to avoid pregnancy during entire follow-up period
- serial beta-hCGs (as tumour marker) every week until negative x 3 (usually takes several weeks), then monthly for 6-12 months – prior to trying to conceive again
- increase or plateau of beta-hCG indicates GTN → patient needs chemotherapy

GTN (MALIGNANT GTD)

- **invasive mole or persistent GTN**
 - diagnosis made by rising or plateau in beta-hCG, development of metastases following treatment of documented molar pregnancy (see sidebar)
 - histology: molar tissue from D&C
 - metastases are rare (4%)
- **choriocarcinoma**
 - often present with symptoms from metastases
 - highly anaplastic, highly vascular
 - no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
 - may follow molar pregnancy, abortion, ectopic, or normal pregnancy
- **placental-site trophoblastic tumour**
 - rare aggressive form of GTN
 - abnormal growth of intermediate trophoblastic cells
 - low beta-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

**GTN Diagnosis**

1. 4 values of persistently elevated beta-hCG plateau (days 1, 7, 14 and 21) or sequential rise of beta-hCG for 2 weeks (days 1, 7, 14) or longer
2. Lung metastases on CXR (rare)

CLASSIFICATION of GTN

- **non-metastatic**
 - ~15% of patients after molar evacuation
 - may present with abnormal bleeding
 - all have rising or plateau of beta-hCG
 - negative metastases on staging investigations
- **metastatic**
 - 4% patients after treatment of complete molar pregnancy
 - metastasis more common with choriocarcinoma which tends toward early vascular invasion and widespread dissemination
 - if signs or symptoms suggest hematogenous spread, don't biopsy (they bleed)
 - ♦ lungs (80%): cough, hemoptysis, CXR lesion(s)
 - ♦ vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
 - ♦ pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
 - ♦ liver (10%): elevated LFTs, U/S or CT findings
 - ♦ brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
 - highly vascular tumour → bleeding → anemia
 - all have rising or plateau of beta-hCG
 - classification of metastatic GTN
 - ♦ divided into good prognosis and bad prognosis
 - ♦ features of bad prognosis
 - long duration (>4 months from antecedent pregnancy)
 - high pre-treatment beta-hCG titre: >100,000 IU/24h urine or >40,000 mIU/mL of blood
 - brain or liver metastases
 - prior chemotherapy
 - metastatic disease following term pregnancy
 - ♦ good prognosis characterized by the absence of each of these features

Lungs are #1 site for malignant GTN metastases. When pelvic exam and chest x-ray are negative, metastases are uncommon.

Investigations – For Staging

- history and physical
- bloodwork: CBC, electrolytes, creatinine, beta-hCG, TSH, LFTs
- imaging: CXR, U/S pelvis, CT abdo/pelvis, CT brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF beta-hCG
 - ratio of plasma beta-hCG:CSF beta-hCG <60 indicates metastases

Table 21. FIGO Staging and Management of Malignant GTN

Stage	Findings	Management
I	Disease confined to uterine corpus	Single agent chemotherapy for low risk disease (WHO score ≤6) 1st line: pulsed – actinomycin D (Act-D) IV q2 wks Alternatives: MTX-based regimen 20% of patients need to switch to alternate single-agent regimen Combination chemotherapy (EMA-CO: etoposide, MTX, ACT-D, cyclophosphamide, vincristine) if high risk (WHO score ≥7) or if resistant to single agent chemotherapy Can consider hysterectomy if fertility not desired or placental-site trophoblastic tumour
II	Metastatic disease to genital structures	As above
III	Metastatic disease to lungs with or without genital tract involvement	As above
IV	Distant metastatic sites including brain, liver, kidney, GI tract	Usually high risk (EMA-CO) with surgical resection of sites of disease Persistence/resistance to chemotherapy Consider radiation for brain mets

Follow-up (for GTN)

- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
 - weekly beta-hCG until 3 consecutive normal results
 - then monthly x 12 months
- stage IV
 - weekly beta-hCG until 3 consecutive normal results
 - then monthly x 24 months

Treatment

- chemotherapy for all stages (see Table 21)

Common Medications

Table 22. Common Medications

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
acyclovir (Zovirax®)	Antiviral; inhibits DNA synthesis and viral replication	First Episode: 400 mg PO tid x 7-10d Recurrence: 400 mg PO tid x 5d	Genital herpes	S/E: headache, GI upset D/I: zidovudine, probenecid
bromocriptine (Parlodel®)	Dopaminomimetic Agonist at D ₂ R Antagonist at D ₁ R Acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin	Initial: 1.25-2.5 mg qhs with food Then: 2.5 mg bid with meals	Galactorrhea + amenorrhea 2° to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas)	S/E: nausea, vomiting, headache, postural hypotension, somnolence C/I: uncontrolled hypertension, pregnancy-induced hypertension, CAD D/I: domperidone, macrolides, octreotide
clomiphene citrate (Clomid®)	Increases output of pituitary gonadotropins which induces ovulation	50 mg daily x 5 days Try 100 mg daily if ineffective 3 courses = adequate trial	Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy	S/E: Common – hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare – ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects C/I: pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding
clotrimazole (Canesten®)	Antifungal; disrupt fungal cell membrane	Tablet: 100 mg/d intravaginally x 7d or 500 mg x 1 dose Cream (1 or 2%): 1 applicator intravaginally qhs x 3-7d Topical: apply bid x 7d	Vulvovaginal candidiasis	S/E: vulvar/vaginal burning
danazol (Cyclomen® – CAN) (Danocrine® – US)	Synthetic steroid that inhibits pituitary gonadotropin output and ovarian steroid synthesis Has mild androgenic properties	200-800 mg in 2-3 divided doses Used for 3-6 months Biannual hepatic U/S required if >6 month use	Endometriosis 1° menorrhagia/DUB	S/E: weight gain, acne, mild hirsutism, hepatic dysfunction C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding, severely impaired renal/hepatic/cardiac function, porphyria, genital neoplasia D/I: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives
doxycycline	Tetracycline derivative; inhibit protein synthesis	100 mg PO bid x ≥7d	Chlamydia, gonococcal infection, syphilis	S/E: GI upset, hepatotoxicity C/I: pregnancy, severe hepatic dysfunction D/I: warfarin, digoxin
fluconazole (Diflucan®)	Antifungal; disrupt fungal cell membrane	150 mg PO x 1 dose	Vulvovaginal candidiasis unresponsive to clotrimazole	S/E: headache, rash, nausea, vomiting, abdo pain, diarrhea D/I: terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin
leuprolide (Lupron®)	Synthetic GnRH analog Induces reversible hypoestrogenic state	3.75 mg IM q1month or 11.25 mg IM q3months Usually ≤6 months, check bone density if >6 months	Endometriosis Leiomyomata DUB Precocious puberty	S/E: hot flashes, sweats, headache, vaginitis, reduction in bone density C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding
menotropin (Pergonal®)	Human Gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development	75-150 U of FSH and LH IM qd x 7-12d, then 10,000 U hCG one day after last dose	Infertility	S/E: bloating, irritation at injection site, abdo/pelvic pain, headache, nausea and vomiting C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy
metronidazole (Flagyl®)	Bactericidal; forms toxic metabolites which damage bacterial DNA	2 g PO x 1 dose or 500 mg PO bid x 7d	Bacterial vaginosis, trichomonas vaginitis	S/E: headache, dizziness, nausea, vomiting, diarrhea, disulfiram-like reaction (flushing, tachycardia, nausea and vomiting) C/I: pregnancy (1 st trimester) D/I: cisapride, warfarin, cimetidine, lithium, alcohol

Table 22. Common Medications (continued)

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
oxybutinin (Ditropan®)	Anticholinergic – relaxes bladder smooth muscle, inhibits involuntary detrusor contraction	5 mg PO bid-tid	Overactive bladder (urge incontinence)	S/E: dry mouth/eyes, constipation, palpitations, urinary retention C/I: glaucoma, GI ileus, severe colitis, obstructive uropathy, use with caution if impaired hepatic/renal function
tolterodine (Detrol®)	Anticholinergic	1-2 mg PO bid	Overactive bladder (urge incontinence)	S/E: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain C/I: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function
tranexamic acid (Cyklokapron®)	Anti-fibrinolytic, reversibly inhibits plasminogen activation	1-1.5 g tid-qid for first 4 days of cycle Ophthalmic check if used for several weeks	Menorrhagia	S/E: nausea, vomiting, diarrhea, dizziness, rare cases of thrombosis C/I: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age <15 yrs
urofolitropin (Metrodin®)	FSH	75 U/d SC x 7-12 d	Ovulation induction in PCOS	S/E: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdo pain C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy
combined oral contraceptive pill (OCP)	Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration		Contraception Disorders of menstruation	S/E: Estrogen-related – nausea, breast changes (tenderness, enlargement), fluid retention/bloating/edema, weight gain, migraines, thromboembolic events, liver adenoma, intermenstrual bleeding Progestin-related – amenorrhea/intermenstrual bleeding, headaches, breast tenderness, increased appetite, decreased libido, mood changes, hypertension, acne/oily skin, hirsutism D/I: rifampin, phenobarbital, phenytoin, primidone C/I: Absolute – known/suspected pregnancy, undiagnosed abnormal vaginal bleeding, prior thromboembolic events, thromboembolic disorder, active thrombophlebitis, cerebrovascular or coronary artery disease, estrogen-dependent tumours, impaired liver function associated with acute liver disease, congenital hypertriglyceridemia, smoker age >35 years, migraines with focal neurological symptoms (excluding aura), uncontrolled hypertension Relative – non focal migraines with aura <1 hour, diabetes mellitus complicated by vascular disease, SLE, controlled hypertension, hyperlipidemia, sickle cell anemia, gallbladder disease
intrauterine device (IUD) copper IUD (Nova-T®) progesterone-releasing IUD (Mirena®)	Copper IUD: mild foreign body reaction in endometrium which is toxic to sperm and alters sperm motility Progesterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last five years	Same as above	S/E: intermenstrual bleeding, bloating, headache (Mirena®), increased blood loss, duration of menses and dysmenorrhea (copper IUD only), expulsion (5% in the first year, greatest in first month), uterine wall perforation (1/5000), greater risk of ectopic pregnancy if pregnancy occurs, increased risk of PID within first 10 days of insertion only C/I: Absolute – known or suspected pregnancy, undiagnosed genital tract bleeding, acute or chronic PID, lifestyle risk for STIs, known allergy to copper or Wilson's Disease (copper IUD only) Relative – valvular heart disease, past history of PID or ectopic pregnancy, abnormalities of uterine cavity, intracavitary fibroids, severe dysmenorrhea or menorrhagia (copper IUD only), cervical stenosis, immunosuppressed individuals

Basics of Hematology	2	Disorders of Secondary Hemostasis	29
Complete Blood Count		Hemophilia A (Factor VIII Deficiency)	
Blood Film Interpretation		Hemophilia B (Factor IX Deficiency)	
Bone Marrow Aspiration and Biopsy		Factor XI Deficiency	
Common Presenting Problems	5	Liver Disease	
Anemia		Vitamin K Deficiency	
Polycythemia		Disseminated Intravascular Coagulation (DIC)	
Thrombocytopenia		Venous Thrombosis	31
Thrombocytosis		Approach to Treatment of Venous Thrombosis	
Pancytopenia		Hypercoagulable Disorders	33
Neutrophilia		Hematologic Malignancies and Related Disorders	34
Neutropenia		Myeloid Malignancies	35
Lymphocytosis		Acute Myeloid Leukemia (AML)	
Lymphocytopenia		Myelodysplastic Syndromes (MDS)	
Eosinophilia		Myeloproliferative Neoplasms	37
Agranulocytosis		Polycythemia Rubra Vera (PRV)	
Leukemoid Reactions		Chronic Myeloid Leukemia (CML)	
Approach to Lymphadenopathy	10	Idiopathic Myelofibrosis (IMF)	
Approach to Splenomegaly	11	Essential Thrombocythemia (ET)	
Microcytic Anemia	12	Lymphoid Malignancies	41
Iron Metabolism		Acute Lymphoblastic Leukemia (ALL)	
Iron Deficiency Anemia		Lymphomas	42
Anemia of Chronic Disease		Hodgkin's Lymphoma	
Lead Poisoning		Non-Hodgkin's Lymphoma (NHL)	
Sideroblastic Anemia		Malignant Clonal Proliferations of Mature B Cells	46
Thalassemia		Chronic Lymphocytic Leukemia (CLL)	
Normocytic Anemia	16	Multiple Myeloma (MM)	
Aplastic Anemia		Monoclonal Gammopathy of Unknown Significance (MGUS)	
Hemolytic Anemia (HA)	17	Waldenstrom's Macroglobulinemia	
Thalassemia		Complications of Hematologic Malignancies	49
Beta-Thalassemia Minor (Thalassemia Trait)		Hyperviscosity Syndrome	
Beta-Thalassemia Major		Tumour Lysis Syndrome	
Alpha-Thalassemia		Blood Products and Transfusions	50
Sickle Cell Disease		Blood Products	
Autoimmune Hemolytic Anemia (AIHA)		Red Blood Cells	
Microangiopathic Hemolytic Anemia (MAHA)		Platelets	
Hereditary Spherocytosis		Coagulation Factors	
Hereditary Elliptocytosis		Acute Blood Transfusion Reactions	
G6PD Deficiency		Delayed Blood Transfusion Reactions	
Macrocytic Anemia	22	Common Medications	54
Vitamin B ₁₂ Deficiency		Antiplatelet Therapy	
Folate Deficiency		Anticoagulant Therapy	
Hemostasis	24	Chemotherapeutic Agents	
Three Phases of Hemostasis		Landmark Hematology Trials	57
Disorders of Primary Hemostasis	26	References	58
Immune Thrombocytopenic Purpura (ITP)			
Heparin-Induced Thrombocytopenia (HIT)			
Thrombotic Thrombocytopenic Purpura (TTP)			
and Hemolytic Uremic Syndrome (HUS)			
Von Willebrand's Disease (vWD)			

Basics of Hematology

Erythrocyte – carries oxygen from lungs to peripheral tissues

Reticulocyte – immature erythrocyte

Neutrophil – granulocyte integral in innate immunity; main cell in acute inflammation

Eosinophil – involved in response to parasites (especially helminths) and allergic response

Basophil – granulocyte mainly involved in allergy and parasitic infection

Lymphocyte – integral cell in adaptive immunity

Monocyte – involved in innate immunity; can differentiate into macrophage or dendritic cell

Platelet – mediator of primary hemostasis

Plasma – liquid component of blood containing water, proteins, coagulation factors and immunoglobulins

Serum – equivalent to plasma minus clotting factors and fibrinogen

Figure 1. Hematopoiesis

- over 10^{11} blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies
- lifespan of mature blood cells
 - erythrocytes (120 days); neutrophils (~1 day); platelets (10 days); lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
 - spleen: part of reticuloendothelial system; removes aged RBCs, removes antibody-coated bacteria/cells, site of antibody production
 - thymus: site of T-cell maturation, involutes with age
 - lymph nodes: sites of B and T cell activation (adaptive immune response)

Complete Blood Count

Table 1. Common Terms Found on CBC

Test	Definition	Normal Values*
Red blood cell (RBC) count	The number of RBCs per volume of blood	$4.2-6.9 \times 10^9/\text{mm}^3$
Hemoglobin (Hb)	Amount of oxygen-carrying protein in the blood	130-180 g/L (13-18 g/dL) (male) 120-160 g/L (12-16 g/dL) (female)
Hematocrit (Hct)	Percentage of a given volume of whole blood occupied by packed RBCs	45%-62% (male) 37%-48% (female)
Mean corpuscular volume (MCV)	Measurement of size of RBCs	$80-100 \mu\text{m}^3$
Mean corpuscular Hb (MCH)	Amount of oxygen-carrying Hb inside RBCs	27-32 pg/cell
Mean corpuscular Hb concentration (MCHC)	Average concentration of Hb inside RBCs	32%-36%
RBC distribution width (RDW)	Measurement of variance in RBC size	11.0%-15.0%
White blood cell (WBC) count	The number of WBCs per volume of blood	$4.3-10.8 \times 10^9/\text{mm}^3$
WBC differential	Includes neutrophils, eosinophils, basophils, lymphocytes and monocytes	
Platelet count	The number of platelets per volume of blood	$150-400 \times 10^9/\text{mm}^3$
Mean platelet volume (MPV)	Measurement of platelet size	
Reticulocytes	Immature RBCs that contain no nucleus but have residual RNA	Normally make up 1% of total RBC count

*Normal values may vary depending on site

Clinical Use of RDW

To distinguish the etiologies of microcytosis:
Fe deficiency – increased RDW (anisocytosis)
Thalassemia minor – normal RDW

Absolute Neutrophil Count (ANC) =
WBC count \times (%PMNs + %bands)
Beware of fever + ANC $<0.5 \times 10^9/\text{L}$ =
FEBRILE NEUTROPENIA

Approach for Interpreting CBC

- consider values in the context of individual's baseline
 - up to 5% of population without disease may have values outside "normal" range
 - an individual may display a substantial change from their baseline without violating "normal" reference range
- is one cell line affected or are several?
 - if all lines are low: consider pancytopenia (see *Pancytopenia*, H7)
 - if RBCs and platelets are low: consider microangiopathic hemolytic anemia (MAHA) (see H21)
 - if single cell line affected: see corresponding section in *Common Presenting Problems*, H5

Blood Film Interpretation

RED BLOOD CELLS

Size

- microcytic (MCV<80), normocytic (MCV=80-100), macrocytic (MCV>100)
- anisocytosis: RBCs with increased variability in size (increased RDW)
 - iron deficiency anemia, thalassemia major, myelofibrosis

Colour

- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
 - iron deficiency anemia, anemia of chronic disease, hemolytic anemias, sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
 - increased RBC production by the marrow

Shape (see Table 2 and Figure 2)

- poikilocytosis: increased proportion of RBCs of abnormal shape
 - iron deficiency anemia, myelofibrosis

Table 2. Common Erythrocyte Shapes

Shape	Definition	Associated Conditions
Discocyte	Biconcave disc	Normal RBC
Spherocyte	Spherical RBC (due to loss of membrane)	Hereditary spherocytosis, immune hemolytic anemia
Elliptocyte/Ovalocytes	Oval-shaped, elongated RBCs <ul style="list-style-type: none"> Elliptocytes: the RBC long axis is $\geq 2\times$ the length of the short axis Ovalocytes: the RBC long axis is $< 2\times$ the length of the short axis 	Hereditary elliptocytosis, megaloblastic anemia, myelofibrosis, iron-deficiency, MDS
Schistocytes (helmet cells)	Fragmented cells (due to traumatic disruption of membrane)	Microangiopathic hemolytic anemia (HUS/TTP, DIC, pre-eclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, prosthetic heart valve
Sickle cell	Sickle-shaped RBC (due to polymerization of hemoglobin S)	Sickle cell disorders: HbSC, HbSS
Codocyte (target cell)	"Bull's eye" on dried film	Liver disease, hemoglobin SC, thalassemia, Fe deficiency, asplenia
Dacrocyte (teardrop cell)	Single pointed end, looks like a teardrop	Myelofibrosis, thalassemia major, megaloblastic anemia
Acanthocyte (spur cell)	Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids)	Severe liver disease (spur cell anemia), starvation/anorexia, post-splenectomy
Echinocyte (burr cell)	RBC with numerous regularly spaced, small spiny projections	Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, storage artifact
Rouleaux formation	Aggregates of RBC resembling stacks of coins Due to increased plasma concentration of high molecular weight proteins	Pregnancy: most common cause; due to physiological increase in fibrinogen Inflammatory conditions: due to polyclonal immunoglobulins Plasma cell dyscrasias: due to monoclonal paraproteinemia, eg. multiple myeloma, macroglobulinemia Storage artifact

Figure 2. Morphology

Table 3. RBC Inclusions (see Figure 2)

Inclusions	Definition	Associated Conditions
Nucleus	Present in erythroblasts (immature RBCs)	Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), extramedullary hematopoiesis (in BM infiltration)
Heinz bodies	Denatured and precipitated hemoglobin	G6PD deficiency (post-exposure to oxidant), thalassemia, unstable hemoglobins
Howell-Jolly bodies	Small nuclear remnant resembling a pyknotic nucleus	Post-splenectomy, hyposplenism (sickle cell disease), neonates, megaloblastic anemia
Basophilic stippling	Deep blue granulations indicating ribosome aggregation	Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, hereditary (pyrimidine 5'nucleotidase deficiency)
Sideroblasts	Erythrocytes with Fe containing granules in the cytoplasm	Hereditary, idiopathic, drugs, hypothyroidism (see <i>Sideroblastic Anemia</i> , H15)

WHITE BLOOD CELLS

- lymphocytes: comprise 30-40% of white cells
 - Reed-Sternberg cell: giant, multinucleated B-lymphocyte
 - ♦ seen in Hodgkin's lymphoma, other lymphoproliferative disorders, reactive nodes
 - smudge cells: lymphocytes damaged during preparation of the blood smear indicating cell fragility
 - ♦ seen in Chronic Lymphocytic Leukemia (CLL) and other lymphoproliferative disorders
- neutrophils
 - normally only mature neutrophils (with 2-4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
 - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B₁₂ or folate deficiency)
 - left shift: increase in granulocyte precursors (bands, metamyelocytes, myelocytes, promyelocytes, blasts) in circulation
 - ♦ seen in acute infections, pregnancy, hypoxia, shock, CML
- blasts
 - immature, undifferentiated cells; associated with acute leukemia, MDS, severe infection
 - Auer rods: clumps of granular material that form long needles in the cytoplasm of myeloblasts
 - ♦ pathognomonic for Acute Myeloid Leukemia (AML)

PLATELETS

- small purple anuclear cell fragments

**Bone Marrow Aspiration and Biopsy**

- sites: posterior iliac crest, sternum, anterior iliac crest
- possible analyses
 - aspiration: histology, flow cytometry, cytogenetics, molecular studies, microbiology (C&S, AFB)
 - biopsy: for histology

Indications

- unexplained CBC abnormalities
- diagnosis and evaluation of plasma cell disorders and leukemias
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of undetermined origin, suspected mycobacterial, fungal or parasitic infections, or granulomatous disease
- unexplained splenomegaly
- confirm normal bone marrow in potential allogenic hematopoietic cell donor

Contraindications

- absolute: hemophilia, severe DIC
- thrombocytopenia not a contraindication – may need platelet transfusion prior to procedure

Common Presenting Problems

Anemia

Definition

- a decrease in red blood cell (RBC) mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
 - adult males: Hb <135 g/L, (13.5 g/dL) or Hct <41%
 - adult females: Hb <120 g/L, (12 g/dL) or Hct <36%

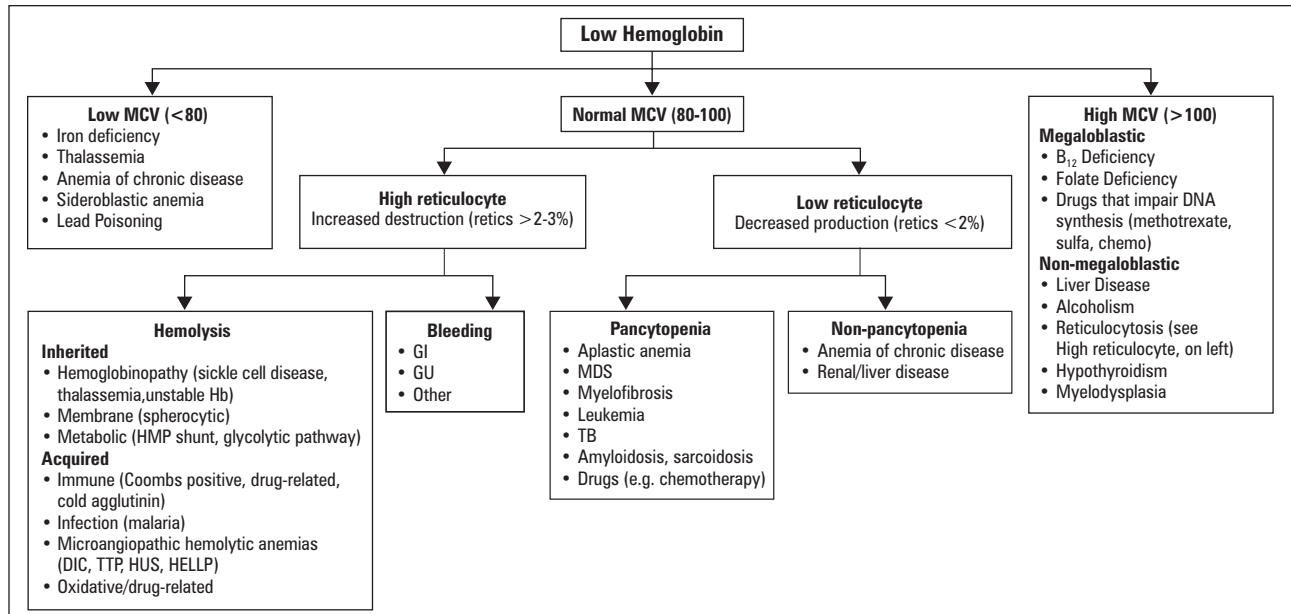

Figure 3. Approach to Anemia

Clinical Features

- history
 - symptoms of anemia: fatigue, malaise, weakness, dyspnea, decreased exercise tolerance, palpitations, headache, dizziness, tinnitus, syncope
 - acute vs. chronic, bleeding, systemic illness, diet, alcohol, family history
 - rule out pancytopenia (recurrent infection, mucosal bleeding/easy bruisability)
- physical signs
 - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L (<9 g/dL), ocular bruits at Hb <55 g/L (<5.5 g/dL)
 - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
 - dermatologic: pallor in palmar skin creases at Hb <75 g/L (<7.5 g/dL), jaundice (if due to hemolysis)

Investigations

- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential (note MCV, RDW)
- reticulocyte count
- blood film
- rule out gastrointestinal disease in iron deficiency anemia
- additional laboratory investigations as indicated (see *Microcytic Anemia*, H12, *Normocytic Anemia*, H16, *Hemolytic Anemia*, H17 and *Macrocytic Anemia*, H22)

Reticulocytes

- Reticulocytes are immature erythrocytes and are markers of erythrocyte production
- Normally they should increase when there is a decrease in RBC
- With blood loss, reticulocytes should increase 2-3x initially and then 5-7x over the next week
- A normal reticulocyte count in anemia should be interpreted as a sign of decreased production

Polycythemia

Definition

- an increase in the number of RBCs: Hb >185 g/L or Hct >52% (males); Hb >165 or Hct >47% (females and African males)

Etiology

- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, “stress” (Gaisböck’s syndrome)
- absolute erythrocytosis
 - primary (low or normal erythropoietin)
 - ♦ polycythemia rubra vera (PRV) (see PRV, H38)
 - secondary (elevated erythropoietin)
 - ♦ poor tissue oxygenation/hypoxia
 - ♦ pulmonary disease: COPD, sleep apnea, pulmonary hypertension
 - ♦ cardiovascular disease: R → L shunt (Eisenmenger syndrome)
 - ♦ RBC defects (Hb with increased O₂ affinity, methemoglobinemia)
 - ♦ carbon monoxide poisoning (heavy smoking)
 - ♦ high altitude
 - inappropriate production of erythropoietin
 - ♦ renal cell carcinoma, cerebellar hemangioblastoma, hepatocellular carcinoma, uterine leiomyomas, ovarian tumour
 - ♦ other: polycystic kidney disease, post-kidney transplant, hydronephrosis, androgens

Clinical Features

- secondary to high red cell mass and hyperviscosity
 - headache, dizziness, tinnitus, visual disturbances
 - symptoms of angina, CHF
- thrombosis (venous or arterial) or bleeding (abnormal platelet function)
- physical findings
 - hepatomegaly, plethora (ruddy complexion) of face (70%) and/or palms

Investigations

- RBC mass: normal suggests relative erythrocytosis (confirms increased red cell production, rules out decreased plasma volume)
- serum erythropoietin (Epo): increased Epo suggests autonomous production or hypoxia and rules out PRV
 - search for tumour as source of Epo as indicated (e.g. abdominal U/S, CT head)
- arterial pO₂: decreased pO₂ suggests hypoxic etiology
- sleep studies if history suggestive of sleep apnea
- carboxyhemoglobin (hemoglobin-carbon monoxide complex) level, hemoglobin O₂ affinity

Treatments

- if secondary: treat underlying cause
 - O₂ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours
- phlebotomy

Must rule out factitious thrombocytopenia – platelet clumping (secondary to EDTA antibodies)

Thrombocytopenia

Definition

- platelet count $<150 \times 10^9/L$

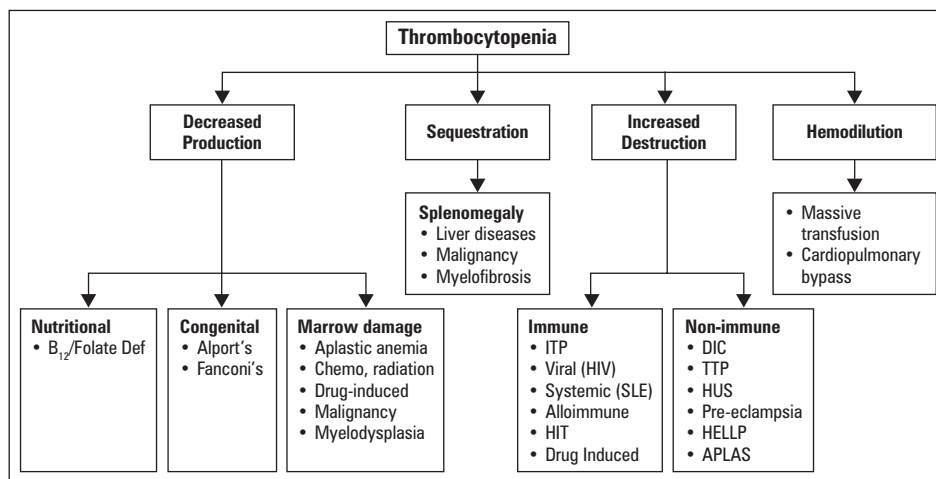

Figure 4. Approach to Thrombocytopenia

Adapted from Cecil's Essentials of Medicine

APLAS = Antiphospholipid Antibody Syndrome

Clinical Features

- history: bleeding gums, epistaxis, bleeding post-surgical procedures, metromenorrhagia
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura
 - hemarthrosis and deep muscle hematomas are rarely initial signs in patients with primary hemostatic disorders
- see *Disorders of Primary Hemostasis*, H26, for complications of thrombocytopenia

Investigations

- CBC and differential
- blood film
 - decreased production: possible other cell line abnormalities, blasts, hypersegmented PMNs, leukoerythroblastic changes
 - increased destruction: large platelets, schistocytes (seen in MAHA)
- work-up for nutritional deficiencies: vit B₁₂, RBC folate
- LFTs

Thrombocytosis

Definition

- platelet count $>500 \times 10^9/L$
- reactive thrombocytosis: acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms)
- autonomous thrombocytosis: due to myeloproliferative or myelodysplastic disorders [e.g. CML, primary myelofibrosis, polycythemia rubra vera (PRV), myelodysplastic syndrome (MDS)]

Clinical Features

- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, constitutional symptoms indicating malignancy
- autonomous thrombocytosis more likely to cause vasomotor symptoms (headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, aquagenic pruritus)
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative disorders

Investigations

- CBC, peripheral blood smear, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, plasma fibrinogen, ferritin)
- if reactive process has been ruled out, bone marrow biopsy may be required to determine cause of autonomous thrombocytosis

Pancytopenia

Definition

- a decrease in all hematopoietic cell lines

Clinical Features

- anemia – fatigue
- leukopenia – recurrent infections
- thrombocytopenia – mucosal bleeding and ecchymoses

Investigations

- CBC and differential, blood film
- investigate secondary causes: HIV test, serum B₁₂, RBC folate, ANA
- often requires bone marrow biopsy to determine cause

PNH = Paroxysmal Nocturnal Hemoglobinuria

Neutrophilia

Definition

- absolute neutrophil count (ANC) $>7.7 \times 10^9/L$

Etiology

- primary neutrophilia
 - hereditary neutrophilia (autosomal dominant)
 - chronic idiopathic neutrophilia in otherwise healthy patients
 - chronic myelogenous leukemia (CML)
 - other myeloproliferative disorders (PRV, ET, myelofibrosis)
 - leukocyte adhesion deficiency
- secondary neutrophilia
 - smoking – most common cause of mild neutrophilia
 - infection – leukocytosis with left shift \pm toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
 - inflammation – e.g. RA, IBD, chronic hepatitis, MI, PE, burns
 - malignancy – hematologic (i.e. marrow invasion by tumour) and nonhematologic (especially large cell lung cancer)
 - stress/exercise/epinephrine – movement of neutrophils from marginated pool into circulating pool
 - medications – glucocorticoids, beta-agonists (e.g. epinephrine), lithium

Left Shift

Refers to an increase in granulocyte precursors in the peripheral smear (myelocytes, metamyelocytes, promyelocytes, blasts). If present, implies increased marrow production of granulocytes (e.g. inflammation, infection, G-CSF administration, CML).

The presence of predominantly blasts in the peripheral smear without cells between mature neutrophil and blast suggests clonal cell disorder (MDS, acute leukemias).

Clinical Features

- look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
- examine oral cavity, teeth, peri-rectal area, genitals and skin for signs of infection

Investigations

- CBC differential: mature neutrophils or bands $>20\%$ of total WBC suggests infection/inflammation
- blood film: Döhle bodies, toxic granulation, cytoplasmic vacuoles in infection
- review other blood counts

Neutropenia

Definition

- mild:** ANC $1.0\text{--}1.5 \times 10^9/L$
- moderate:** ANC $0.5\text{--}1.0 \times 10^9/L$ (risk of infection starts to increase)
- severe:** ANC $<0.5 \times 10^9/L$

Etiology

- decreased production
 - hematological diseases – idiopathic, aplastic anemia, myelofibrosis, BM infiltration
 - infection – TB, typhoid, EBV, malaria, viral hepatitis, HIV
 - drug-induced – alkylating agents, antimetabolites, anticonvulsants, antipsychotics, anti-inflammatory agents, anti-thyroid drugs
 - toxic – high dose radiation, chemicals (e.g. benzene, DDT)
 - nutritional deficiency – B₁₂, folate
 - idiopathic – constitutional neutropenia, benign cyclic neutropenia
- peripheral destruction
 - antineutrophil antibodies
 - spleen or lung trapping
 - autoimmune disorders – RA, SLE
 - Wegener's granulomatosis
 - drugs – haptens (e.g. α -methyl dopa)
- excessive margination (transient neutropenia)
 - idiopathic (most common)
 - overwhelming bacterial infection
 - hemodialysis
 - racial variation (e.g. people of African descent commonly have mild neutropenia)

Clinical Features

- fever, chills (only if infection)
- infection by endogenous bacteria (e.g. *S. aureus*, gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth and throat following colonization by opportunistic organisms
- avoid digital rectal exam

Investigations

- depends on degree of neutropenia and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

Treatment

- regular dental care – chronic gingivitis and recurrent stomatitis major sources of morbidity
- febrile neutropenia (see [Infectious Diseases](#), ID44)
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
 - if no response to G-CSF, then immunosuppression (e.g. steroids, cyclosporine, methotrexate)

Lymphocytosis

Definition

- absolute lymphocyte count $>4 \times 10^9/L$

Etiology

- infection
 - viral infections (majority)
 - TB, pertussis, brucellosis, toxoplasmosis
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. rheumatoid arthritis)
